We shall now proceed to describe, in a general manner, the process of the growth of the plant, and the gradual formation of these several portions. The germination of the seed is a mystery of nature yet undeveloped; but when the seed has germinated, and the existence of the plant has commenced, the labours of physiologists have enabled us to trace the various processes by which its increase is effected. Mr Knight has related, in the papers which we have already mentioned as having been published in the Philosophical Transactions, a series of most conclusive experiments made by him, in order to ascertain the course of the sap, the manner of its deposition, and the method of its influence on the growth of the tree. He removed a ring of bark about half an inch in breadth, from a number of trees, and compared the growth of these trees with that of others not so treated. This was done early in the spring. The effects were, that although the branches shot, and the parts above the incisions in the incised trees did not appear to suffer, there was no increase in the parts below the incisions; and that while the upper lips made considerable advances towards establishing a reunion, the lower lips of the wounds remained without alteration. In the course of the summer the wood from which the rings of bark had been stripped, became dry and lifeless to some considerable depth beneath its surface, and several buds made their appearance below the incisions. In those trees in which a shoot produced by one of these buds was suffered to remain, the parts of the stem below the shoot very soon began to increase in size, while the part between the shoot and the annular incision still remained so nearly stationary as to be, in the autumn, almost a year's growth less in diameter than the part of the stem above the incision. Mr Knight varied these experiments in many different ways, but in every case he found the result to be the same; that is, those parts of the stem and branches which were above the incisions, and had a communication with the leaves through the bark, increased rapidly; while those below the incision scarcely grew at all, but remained with little perceptible change, until a new communication was obtained through the bark with the leaves of a shoot from some bud below the incision; the increase of the timber thus evidently depending upon the growth of the leaves.

These experiments were so far conclusive as to establish that the current of sap which ran upwards from the roots, was not impeded in its passage by the annular incisions and the removal of the belt of bark; but that it was probably the downward current which was interrupted, and also that it was this downward current by which the annual increase of the tree was effected. By a series of experiments with coloured infusions, Mr Knight traced the upward current through the pores of the wood beyond the annular incisions in the bark, and found that it had neither coloured the bark nor the sap between it and the wood. He traced the coloured infusion along the leaf-stalk into the leaf, through one series of vessels; and he observed another series of vessels which were conveying a colourless fluid in an opposite direction, that is, out of the leaf. He traced this second series of tubes downwards, and found that they entered the inner bark, and, without having any communication with the tubes of the wood, descended through the inner bark from the very extremities of the leaves, apparently to the points of the roots. Mr Knight considers that there are two series of these descending tubes, one of which forms the new annual layer of alburnum, and the other the new annual layer of internal bark. It thus appears that the sap is conveyed upwards through the pores of some part of the wood, into the leaves, and that when there, probably by its exposure to light and air, and by the evaporation which takes place, it undergoes some peculiar process of elaboration which fits it for contributing to the sustenance and growth of the tree. It also appears that the cause of the growth is the deposition which takes place in the downward passage of this perfected sap. The sap, after this curious preparation in the leaves, is called cambium.

The same persevering physiologist then pursued his investigations a step farther. He took trees, and not only removed a ring of bark, but also a ring of the younger wood, to such a depth as to cut through and remove the whole of the alburnum. These trees did not exhibit the slightest symptom of vegetation in the ensuing spring; which fact evidently proved that the ascent of the sap had been prevented, and also that it had been prevented by the removal of the alburnum; for the previously-mentioned experiment had shewn that the removal of the bark was not attended with such an effect.[1]

It is the generally received opinion that the ascent of the sap through the alburnum is the reason that this graually becomes perfect wood, in consequence of the de- psition of matter which then takes place, and fills up its pres; so that the *rationale* of the process appears to be, at the sap of one year deposits nourishment, in its up- ard passage, which strengthens the sap-wood or alburnum previous years; that then, after being elaborated in the aves, it becomes cambium, and in its descent adds bulk oth to the alburnum and the bark. It must however be oserved, that there is not in timber any appearance of gradual change from alburnum to perfect wood. On e contrary, in all cases the division is most decided; ne concentric layer is perfect wood, the next in succes- on is alburnum. Mr Knight gives it as his opinion, that towards the conclusion of summer, the true sap, that is, e cambium, simply accumulates in the alburnum, and us adds to the specific gravity of winter-felled timber, and creases the quantity of extractive matter." He says he as "reason to believe that the true sap descends through e alburnum as well as through the bark; that is, that the perabundance of true sap is there deposited, and enriches e upward current of aqueous sap, or the sap of the ensu- g spring." In confirmation of this, he tested the ascend- g current of spring sap, extracted from the trunks of trees various heights, and found that the specific gravity in- reased with the height, and that the taste also very sen- bly altered. He argues from the foregoing facts, that by irdling trees in the spring, and suffering them to grow un- l the ensuing winter, the wood above the girdling would e increased in specific gravity. In one experiment, in hich the belt of bark had been abstracted for several ears, he found that the specific gravity of the wood above as 0·590, while below it was only 0·491, and also that the lburnum had acquired a greater degree of hardness, and onsequently of durability. This is important, for Du Ha- ncl established by experiment very conclusively, that the trength of timber of the same species varied very nearly s its weight. There are many other theories as to the rowth of plants, founded also on experiment, but we can- ot, within the limits of this article, enter into the *rationale* f the whole of them. We have therefore taken this of Ir Knight, because, although there may be some points in t which may be objected to, we conceive that, as a whole, t probably approaches more nearly to the truth than does ny other, and indeed leaves but little doubt upon the nind as to its general correctness.

---

[1] This experiment is continually making on a far more extended and therefore more conclusive scale, in the removal of the whole of the bark excepting the liber, from the cork oak, *Quercus Suber*, which takes place once in about eight or ten years, not only without injury, but with actual advantage, to the tree, which vegetates with increased luxuriance.

There are not less than 140 species of oak known, and lthough there are many sorts cultivated and growing in England, botanists and arborists agree that there are prin- cipally two varieties; these are, the Durmast oak, and an- other, which is commonly called the old English oak, al- hough both are supposed to be indigenous. In the Dur- nast oak, the *Quercus sessiliflora*, the acorns grow in clus- ers close to the twig, and the leaves are set on short leaf- stalks: while in the old English oak, the *Quercus Robur*, or *Quercus pedunculata*, the acorns grow generally singly, at most two together, on stalks of from one to two inches n length, and the leaves are close to the twig, without the intervention of any length of leaf-stalk. These are the principal distinguishing marks between the two varie- ties. Many writers attempt to draw distinctions from the colour and shape of the leaves, and the colour and appear- ance of the bark; but it is doubtful whether these may be depended upon, as, from a careful examination of the evi- dence, it is more than probable that the colour and appear- ance vary much with the soil and locality. There is no doubt, however, as to the comparative inferiority of the tim- ber of the Durmast oak. Almost all the English writers on timber have asserted it, and both Buffon and Du Hamel cor- roborate their assertions, and give a most decided prefer- ence to the oak bearing large acorns on separate stalks, over the oak bearing acorns in clusters; which characteristics are just the distinguishing differences that have been particularized as existing between the English and the Durmast oaks.

In favourable soils the old English oak has seldom more than twelve to fifteen concentric layers of alburnum; but in the Durmast oak there are frequently from twenty to twenty-five or even thirty. This proves at once, by analogy, the inferiority of the Durmast oak; for it is an established fact, that the best hard-wood timber is that in which the proportion of heart-wood to sap is the largest; besides which, the numerous layers of alburnum form the basis of a proportion which shows the greater age the Durmast timber must attain before it becomes perfect wood. And therefore it is evident, that in order to attain large scantling, comparatively older timber must be felled, and consequently a greater risk be incurred of its being overgrown. The following table of the number of concentric layers of sap-wood observed in various species of timber trees is extracted from a valuable work on Naval Timber by Patrick Matthew; a work which abounds in much sound practical information, though mixed up with many things irrelevant to its subject.

Trees of Home Growth.

Common oak, some trees	10,	others 14,	others 18.
Spanish chestnut,	2,	5,	6.
Scotch elm, *U. Montana*	16,	25,	32.
English elm, *U. Campestris*	0,	10,	0.
Red-wood willow	8,	14,	0.
Laburnum	3,	5,	0.
Wild cherry	16,	24,	0.
Black Italian poplar	9,	0,	0.
Scotch fir	20,	30,	40.
Pinaster	0,	10,	0.
White larch	5,	12,	18.

Trees of Foreign Growth.

Memel fir	0,	others 44,	others 0.
Red Canada pine	0,	100,	0.
Yellow Canada pine	38,	44,	0.

Several of these, which are not cultivated generally as timber trees, are yet valuable, and are made available for local building purposes, and for the manufacture of the conveyances and implements for agriculture. Of these, the red-wood willow may claim the first rank in utility. It is a timber much used in France in cottages and farm buildings, and it has the advantage of being very easily worked. The numerous varieties of the willow tribe are also useful in the manufacture of baskets. The woods of the laburnum, the cherry, and the apple and pear trees, are greatly used by cabinet-makers for articles of furniture.

Although in most parts of England there is soil favourable to the growth of timber, it may well be supposed that all soils are not equally favourable to all timber, nor will they produce timber of equally good quality. Thus in England the Sussex oak has always been celebrated as being superior to all other; and in France the oak of Provence enjoys a similar reputation. Still, an oak tree grown in a soil but ill adapted for it, as, for instance, a marshy soil, will retain its superiority of species over the inferior timbers, as the willow and the poplar, to which such a soil is less unfavourable, although in quality it will fall very short of the standard of perfection for oak timber. In fact, oak grown on such soils will in some measure partake of the qualities of the timber to which they are better adapted, and be of more open texture, of softer fibre, and of less durability than average oak timber. Oaks of slow growth, those, for instance, from the mountains of Scotland, and from Cumberland and Yorkshire, are proverbially hard and durable. The oak from marshy soils is often of a dull-red colour, or has "foxey" stains in it, as this incipient decay is called. These stains are generally around the heart of the tree. Timber grown in loose soils is often what is termed "quaggy;" that is, the centre of the tree is full of shakes and clefts. Sometimes a shake will extend around a great portion of the trunk, between two of the annual concentric layers, so as to divide them from each other. This is called a cup-shake, and the timber is said to be "cuppy." It is not attributable to the soil, but is supposed to originate in the effect of frosts on the aqueous sap in its ascent. When the alburnum of a tree has been wounded, or a branch improperly lopped or damaged, the subsequent growth of the tree will cover it, and it is then called a rind-gall, which, should the injured part have had time to become decayed, or partially so, or even sodden with the rains, will frequently cause an extensive rottenness in the plant. This is remarkably the case with elm timber. Doatiness, probably dottiness, which is a spotted or speckled appearance, like small stains in the wood, is most commonly a disease of beech timber; it is, however, occasionally seen in all, and frequently in the American oak. These diseases are in general incidental to the soil.

In treating of soils in connection with the qualities of the timber which grows upon them, it may be necessary to remember that the object is not to compare various sorts of timber, but to compare the differences in the same species in connection with the soils which produced them. It may also be observed, that as oak is by far the most valuable timber of English growth, the general inquiries we may enter into in the course of this article principally apply to it, unless other species of timber are particularized.

We have already casually adverted to marshy soils, and to the state of the timber grown on them. The grain of such timber is open, its colour of a deep yellow, sometimes with a tinge of red, especially towards the heart; the texture is soft, and the fibre coarse. The quantity of alburnum, and also of bark, is large in comparison with the quantity of perfect wood, and the outer surface of the bark is very coarse and rough. The wood splits easily, and when split it has not the same bright and varnished appearance possessed by the best timber. The chips from the axe do not cling well together, but fall into separate fragments; and a shaving or a small splinter may be easily crumbled between the finger and thumb. When such timber is weighed, although it is far more saturated with moisture, it is of less specific gravity; and when weighed after seasoning, the weight lost will be comparatively greater. Such timber, it is evident, will be more subject to decay, and to become worm-eaten, the softness of its texture inviting the attacks of these insects.

These peculiar characteristics attach more or less to timber grown in all soils which are of a moist nature, whether they are marshy, or wet from long-continued periodical inundations. They also apply to timber grown in deep sandy soil, in which almost the only nutriment for the roots is the water which percolates downward, and the bottom damps which rise upward through it. In all these soils the timber is of rapid growth, and the trees attain early to a large size. A similar result attends the timber grown in sandy soils on a clay bottom, for the water which falls not being able to penetrate the clay, cannot escape, and the roots of the trees are therefore virtually in the same circumstances as if they were growing in marshy land. As a general axiom, timber trees have an antipathy to stagnant waters; and therefore these observations on marshy soils, and on sandy soils with clayey bottoms, refer themselves to this fact. The soil generally the best adapted for the growth of timber appears to be a rich loam. This may have a considerable admixture of sand, without any apparent detriment to the timber. In such soils roots can penetrate and spread without difficulty, while the loam is capable of retaining sufficient moisture to dissolve and hold in solution the various substances that are found combined with it, so as to fit them to be absorbed as food by the roots of the plants. If the soil be too sandy, it neither retains the moisture sufficiently long in it, nor does it contain adequate nutriment. If, instead of a loam, some of the very stiff clays be mixed with the sand, they do not counteract this quality; for although such clay is capable of combining with a great quantity of water, it will not easily absorb and mix with it; and the tender roots have great difficulty in penetrating the masses of clay. For these reasons, soils composed wholly of stiff clay are not favourable to the growth of good timber, but the lighter clayey earth produces very fine oaks. As has been before stated, sand or gravel, with a large mixture of rich loamy earth, is precisely that sort of dry generous soil which affords ample nourishment to the roots of trees, and allows of their spreading themselves freely in search of it. Of all timber, however, oak accommodates itself most easily to soil; growing in almost every thing but sterile sand, if there be sufficient depth of stratum. Wherever oak will grow, even in those soils the least genial to its growth, it is a valuable timber. This fact cannot be too often pressed upon the attention of landholders. It is admirably adapted for planting in hedgerows between arable fields, because it is found to be less destructive to the undergrowth than almost any other timber; and as its roots seek their nourishment deep in the soil, they not only do not impoverish the ground for the growing crop, but are themselves protected from any injury which they might otherwise sustain from the tillage. Oaks so planted require, however, to be protected during several years, as their early growth is slow. The timber grown in such exposed situations is seldom large; the trees are stunted and crooked; but this rather increases their value for shipbuilding purposes, as they convert as compass or knee timber. The timber of hedge-row oak is very close grained; that of park-grown oak is more open, and the trees being better protected, spread more freely and grow to a very large size, with strong lateral branches; while forest oak will frequently grow to a great height without pushing out any lateral shoots. Forest oak is invariably inferior in quality to that which grows singly; and in forests the trees that grow on the skirts are always the best timber. The oak flourishes in variable climates, which is probably the cause of the superiority of the English oak.

In whatever soil planted, each vegetable will retain its own peculiar characteristics. These apparently result from some property inherent in the plant itself, which leads it to extract only that nourishment from the soil which is appropriate to it. This has been illustrated by the example of a pea and a grain of wheat both planted in the same soil, and both treated in exactly the same manner: the corn will have absorbed silex from the earth, which will visibly form a component of its stalk, while the pea will not have taken up any. This indicates that at least a degree of selection with respect to their food is inherent in vegetables, without which indeed it would be difficult to account either for plants of various sorts all flourishing equally well in the same soil, or for others which cannot be reared in certain soils. This selection of food is however limited; for it is a well-ascertained fact that vegetable life is destroyed by the same poisonous substances that are fatal to animal life, and that plants do not possess the power of refusing to absorb such substances when mixed with the food in which their roots are plunged. Although the root of corn would absorb silex and the pea refuse it, they would both perish from the unavoidable absorption with their food, of substances inimical to animal and vegetable life. This is, however, merely saying that the vegetable is not possessed of greater powers of discriminating the beneficial from the hurtful, than is the animal under similar circumstances.

A curious fact connected with the supply of food for trees is also established, proving that there is not only a proportion between the spread of the roots and that of the branches of tree, but that the branches on any one side of the trunk f the tree are dependent for their support on the roots hich protrude from the trunk on that same side. Both uffon and Du Hamel found experimentally, that when the mbs and branches of any part of a tree showed symptoms f decay, the corresponding roots were invariably in a disased state. They also found that on that side of a tree om which the roots had pushed most vigorously, the annual oncentric layers of wood were thicker, and that consequent- the form of a section of the tree would be eccentric toards that side.

The facility with which the roots of plants seek out for emselves the best localities, is surprising. If two trees of fferent species be growing on the edge of a marshy space, at tree which requires most moisture will push its roots wards the marsh, while that which requires a dry soil will ish its roots into the dry firm ground. Du Hamel relates instance in which he dug two trenches crossing each her at right angles; he then returned the soil into these enches, and planted a tree at the point of their intersecon. Some years after, upon examining the roots, it was und that they had invariably pushed into the four lines of enches, leaving the intermediate undisturbed earth wholly touched by them.

An equally important consideration with the quality of e soil, is its quantity, that is, its depth from the surface. fact, in speaking of soils in connexion with the growth timber trees, it must of course be understood that it is t merely the surface-soil which is meant, but that soil in hich the roots of the trees would push and spread,—the il for several feet in depth. It often happens that the rface-soil may be well adapted for tillage and for vegetaon, and yet the sub-soil, that which is essential to the owth of timber trees, may be totally incapable of supplyg them with nourishment. Trees which grow singly, as hedge-rows or in parks, do not require equal depth of il with those which grow in forests, because they have the wer of spreading their roots in search of food. But for rest trees, either oak, chestnut, or beech, a depth of at least ur feet of appropriate soil is absolutely necessary to proce fine timber trees. Elm and ash do not require so eat a depth.

Buffon has given a scale for the ages at which it is desirle to fell timber. It is dependent upon the depth of soil in hich it grows. He says that a depth of from two to three et will not support a tree in a thriving condition for a nger period than fifty years. From three to four feet of il will enable the tree to continue improving until about venty years old; and in a soil from four to five feet deep it ll flourish for a century. These periods are for strong and vourable soils. In lighter soils at least ten years must be ken from each period, and the timber will then also be ferior in quality. As a general rule, the more generous d favourable to the growth of the timber the soil may be, e longer it is advantageous to wait before felling it. Trees ould never be allowed to become stag-headed, that is, to ve their upper branches bare of leaves. It is in the top anches that the first symptoms of the decline of the tree e to be perceived. The leaves have a faded, weakly aparance, gradually diminish in number, and finally the anches become barren of foliage, and decay. The least pearance of want of vigour in the vegetation of the top a tree should be the signal for its being felled; and en then it is also a sure token that the timber is past its ime.

The nature of the soil in a tract of country may be obrved, either by opening it, or by examining the products. us, at all times of the year, if plants which grow only on rshy land are found on any tract, we may evidently asme that tract to be marshy land, whatever its temporary pearance may be. The nature of the sub-soils may often be ascertained by the ditches. The goodness of earth is easily tested by making an excavation in it. If the whole of the excavated earth can be returned into the cavity, the soil is poor, but if, on the contrary, there is an excess, its quantity is a sure criterion by which to judge of the richness.

In the preceding observations as to soil, moisture has been decried as unfavourable to the growth of good timber; but it must be observed, that a deficiency of moisture has also its evils, although they are not of the same kind as those which arise from a superabundance of it. Water is absolutely necessary to the growth of timber; for even if the soil be rich, and light, and well adapted for the reception of the roots, and for affording them nourishment, there must be sufficient moisture in it to form a vehicle for a supply of that nourishment, otherwise the trees will be of very slow growth, not from the lack of proper nourishment, but from the want of a sufficient supply. The timber does not appear to suffer from this in its quality, but in its size. On the contrary, indeed, wood of such growth is extremely heavy, hard, and dense, as, for instance, the Scotish mountain oak. Where there is a greater supply of moisture, the growth of the timber will be more rapid; and, in consequence, although its fibre will be tough, its grain even, and its colour the same as the other, the concentric layers will be thicker, and therefore there will be fewer of them in the same space; but, to compensate for this, we have in a less number of years an equal sized tree, which has the advantage when felled of being in its prime, while the tree of slower growth may have already, from great age, the defects attendant on what is called overgrown timber. There is also another point to be considered; the quicker the growth of the tree, the more it will shrink when converted as timber. Trees of rapid growth, therefore, are not fitted for any thing but large conversions. Timber of slow growth, and of considerable age, is by far the best adapted for panelling and for furniture.

These remarks afford an idea of the difference in the appearance of timber grown on good soil from that produced on bad soil. As to this difference, it may however be desirable to enter more into detail. An oak tree, grown on the soil adapted to the development of its best properties, not only has its concentric layers thin and close together, but they are also of very uniform thickness, and the texture of the grain is fine. When the wood is split it has a glossy varnished appearance, and is of a very pale yellow or straw colour. There is sometimes as much as one fourth difference in weight between samples of oak timber; and the heaviest loses a much less proportion of its weight in drying, and will also, if immersed in water, absorb less, than the lightest. The alburnum of the best timber is small in quantity, and the bark thin and of an even smooth texture. In breaking such wood, it produces a sharp decided noise. Having comparatively little moisture in its composition, and being less hygrometric in its nature than wood of more open texture, it is little subject to decay; and its grain being hard, it is not easily pierced by insects.

The great size to which oak trees will attain when favourably situated as to soil and locality, is truly astonishing. We will mention two instances as examples of this fact. One is the celebrated chapel-oak of Allonville in the Pays de Caux in France, which is still standing. The other is that of an oak which was felled in Monmouthshire in 1791. The oak of Allonville measures at its base thirty-five feet in circumference, and at six feet above the level of the ground it is twenty-six feet in girth. It is hollow, and the interior is fitted up as a chapel. This transformation was effected in 1696. The computed age of the tree is between eight and nine centuries. The other instance, the Monmouthshire oak, produced, when it was converted, the following enormous quantity of materials:—

The main stem, 91 feet long, when sided,	330 cubic feet.
A branch 29 feet long, sided 17 inches,	58 —
— 24 — 19 —	60 —
— 19 — 17 —	38 —
The two main slabs produced 86¼ feet of 3 inch-plank; other conversions; in all,	216 —
13 sided knees, taken together,	217 —
Other minor but useful conversions,	276 —
Total,	1195

the weight of which was nearly 30 tons. The bark weighed 3 tons 17 cwt. 3 qrs. There were 31¾ cords of cord-wood, 84 hogshead, 67 barrel, and 106 kilderkin staves, 256 coopers' ends: 28 hogshead, 38 barrel, and 49 kilderkin heads were also converted from the slab wood.

The largest oak on record grew in Dorsetshire. It was called Damory's Oak, and was used as an ale-house. It was sixty-eight feet in circumference, and the room formed in it was sixteen feet in length. This tree was blown down in 1703.

As a general average of the size of oak timber, 56 cubic feet for each end or log of rough timber, and 30 cubic feet for each end of sided timber, may be assumed as tolerably correct. In order to convert rough timber into sided timber, about two thirds the diameter of the rough log, in the middle of its length, is assumed as the most advantageous siding; and, on an average, it is estimated that not above one third of each log or end of rough timber is used in the principal conversion from it, and this principal conversion is estimated to be about three fourths of the total conversions.

In consequence of the great value of the bark of oak, it is the practice to fell the timber in the spring of the year, because then the bark is easily detached from the tree, while the bark of winter-felled timber is lost. There can be little doubt, however, that the durability of the wood is much deteriorated by this practice. It was a received opinion among the ancients that timber should be felled in the fall of the year; and not only do modern experiments confirm this opinion, but modern discoveries as to the flow and return of the sap, and its nature at various seasons, tend to show the reason for its correctness. The practice which almost all the eminent arborists have recommended, and supported by their experiments, is to bark trees standing in the spring, and then allow them to remain in this state at least one twelvemonth. This was not an uncommon practice in some of the midland counties of England, and was first strongly recommended in the reign of James the Second by Dr Plott, an arborist of great celebrity at that time. Buffon presented a memoir in 1738 to the Royal Academy of Sciences in Paris, "on increasing the Solidity, Strength, and Durability of Timber;" for which purposes it was recommended to strip the tree of its bark during the season of the rising of the sap, and then to leave it to dry completely before being felled. Du Hamel gives most minute accounts of experiments made by himself, all tending to the same conclusion; and Dr Hunter, in his notes on Evelyn's Sylva, says, "that by stripping off the bark, and allowing the tree to stand and die before it is cut, the sappy part becomes as hard and firm as the heart." Here is a collection of opinions, of such weight, that the general fact which they assert must be considered to be established beyond contradiction. Buffon also says that he caused pines, firs, and other species of evergreens, to be barked standing; and as he found them live longer after the operation than oaks which had been also stripped, he considered their wood acquired proportionately greater hardness, strength, and durability. He recommended the practice for fir trees destined to be converted into ships' masts.

Elm, of which there are two principal varieties, like oak, will not bear a damp soil with stagnant waters, but it thrives well in moist declivities, provided the land be not too rich. The trees grown on too damp a soil either die prematurely, or their timber is of a soft spongy nature, and prone to decay. There are two British varieties of this timber, the *Ulmus Montana*, or Wych elm, and the *Ulmus Campestris*, or, as they are sometimes called, the Scotish and the English elms. Of these the Wych elm is decidedly the most valuable as timber, and, when used in situations where it is kept constantly moist, is extremely durable; but no elm timber will bear the trials of change of temperature and moisture to which oak in all its varieties is comparatively insensible. The close and interwoven grain of elm, the absence of decided longitudinal fibre, and its power to resist rending from exposure to the heat of the sun, and the alternations of weather, cause its timber to be very useful for small articles, such as the blocks used in the rigging of a ship. It is valuable in many parts of the millwright's machinery, where the wood is subjected to great friction. It is also valuable and much used both for the timbers and for the planking of ships below the surface of the water; and the planks of clinker-built boats are very generally of elm. There is one peculiarity about elm timber, namely, that the alburnum or sap-wood is possessed of nearly equal power to resist decay with that which is matured; that is, when both are used in situations where they are not exposed to alternations in moisture. A variety of timber has of late years been introduced into the market under the name of Canada elm, or American rock elm. It is a smooth, even textured, pale coloured, and strongly fibrous wood, almost devoid of knots, and admirably adapted for boat-building, and all works which require a flexible and close-textured wood. The Canada elm appears to have many of the peculiarities of toughness and flexibility which distinguish the ash.

Chestnut, *Fagus Castanea*, and Beech, *Fagus*, appear to suffer the least of all the timber trees from being planted in moist sandy soils; but as the chestnuts push their roots far downwards, they require a proportionate depth of soil. The roots of beech, on the contrary, spread widely, but without going to any considerable depth. Beech is a timber which easily adapts itself to and flourishes in almost any soil. Even among rocks its roots will, like those of firs and larches, insinuate themselves into the smallest fissures, and find means to extract sufficient nourishment to produce a useful timber. Beech-timber, when used shortly after being felled, and for works where its dampness will be continued, is a long-enduring wood. It is largely applied in the mercantile navy, for the lower planks of the bottom of ships. The best variety has its wood of a yellow tinge. Chestnut is even a more durable timber than oak, and was much used formerly; but the cultivation of it has been so neglected that few trees remain in this country. Ash, *Fraxinus Excelsior*, which is another valuable timber tree, accommodates itself to all soils. It will grow in marshy grounds and in arid lands, in depth of soil or in shallow soils. It will push its roots into hard gravelly bottoms, and even into the sandstone rocks; but the ash-timber from very poor soils is brittle, and loses the elasticity which is the valuable peculiarity of this wood. Ash is a very useful timber for carts and implements of husbandry, for machinery, for tools of almost all trades; and it supplies oars to our shipping. Of late it has also been much used in the construction of the beds for locomotive steam-engines, tenders, and carriages.

In consequence of the immense consumption of timber for the maintenance of our fleets, there is much imported. We import oak of excellent quality as planking, from the forests on the shores of the Baltic, especially from those of Poland. From Italy and from both shores of the Adriatic, sided timber and plank are imported in large quantities. The Italian timber is extremely subject to rends, but is both strong and durable; and the Adriatic oak has been lebrated for centuries. The Americas do not produce he oak timber; but considerable quantities are imported om Canada, in consequence of the lowness of the price at hich it can be sold in England. There are two sorts of k growing in America, the white and the red, but both e very inferior to European timber. There is, however, American oak, called the live oak, produced principally the Floridas, which has the character of being among the ost durable timbers in existence. It is said to be compa- tively incorruptible, but it is not a timber much known in ritain. The great resource of our dock-yards for timber large scantling is an African timber, called Tortosa, ore commonly only "African." It is a heavy, hard, close- ained, and even textured wood, well adapted for beams, and r internal works, but does not resist alternations of mois- re, and deteriorates rapidly whenever it is in contact with on. The wood round the bolt-heads is carbonized in an credibly short space of time—incredible when the strength, xture, and hardness of the wood are considered; but it pears to be a timber wholly without any protective olea- nous or terebinthinous juices. There are several species timber that are much used in Britain in the construc- n of merchant-ships, but which are unknown in the royal ck-yards. We shall in a subsequent portion of this article tice these, for the purpose of showing their relative values. e consider that the most satisfactory course we can pur- e to effect this object, without occupying more space than n be appropriated to this article, will be to give the tabu- arrangement of woods, as enforced by Lloyd's surveyors, der the direction of the committee of that establishment.

We have hitherto confined our remarks to the hard-wood nber trees, and have said but little of the numerous firs ich are so valuable to us. Their timber is admirably apted, by its growth, lightness, and strength to supply our vies with masts and spars; while, from its comparatively all cost, and the ease with which it is worked, it is also ed very largely for all purposes of building. Indeed it is estionable whether fir is not more generally useful to us an any other species of timber. Du Hamel, in his treatise *u Transport et de la Conservation des Bois*, has drawn distinction between firs and pines, although it is usual to signate the timber of both as fir timber. Pines, he says, ve the leaves thready and slender, growing in clusters om the same leaf-stalk, while firs have straight leaves, each owing separate, but many growing on the same leaf-stalk, e the teeth of a comb. These are the general character- ics between the two sorts of trees which produce fir tim- r. The pines grow with their trunks much less tapering wards their tops than the firs; they are therefore, from ape, more adapted for masts than firs. Their wood is also re resinous, and the resin is of a more glutinous nature, d therefore less easily evaporated; it also, in consequence this quality, enables the timber to resist better the absorp- n of water or moisture when exposed to it. The pine is re durable than the fir, and its fracture is, even when rtially decayed, much more fibrous, and takes place with re previous warning. The timber of the pine, when althy, is close-grained, even textured, and of a bright-yel- w colour. The fir is, although frequently little inferior appearance in other respects, always of a much paler ade of colour.

The most valuable of all the varieties of fir timber is that hich is called Riga fir. It is the red-wood pine of the rth of Europe, the *Pinus Sylvestris*, which, although read over a very large portion of the globe, appears to urish in its greatest perfection in the forests of Lithuania d Poland, where the cold is severe and the soil generous. ga fir is not only extremely flexible and elastic, but is by r the most durable of all the pine timbers; and as long as could be procured of sufficient size, it was therefore gene- lly used in the royal navy not only for topmasts, but also to build the lower or standing masts. At present, from the increased difficulty of procuring large sticks, the use of it is confined to topsail-yards and the smaller description of spars. The American continent also produces this red-pine timber of good quality, although much inferior to that of the north of Europe. It is imported from Canada and from Virginia. The Canadian red pine is of small size, seldom exceeding fourteen hands. The Virginian pine is large, sticks of twenty-four and twenty-five inches in diameter not being uncommon. It is a resinous and flexible wood; but the sticks are more subject than the Canadian red pine to the defect of having large knots in them, which, from not being firmly united to the surrounding timber, that is, not being what is technically called "well collared," injure its value. The red pine thrives extremely well in Scotland, where it is called Scotish fir. There are many extensive forests of it in that part of Great Britain, but the timber will not bear comparison with that which is imported. Notwithstanding this, Du Hamel makes "Scotish pine" the generic name of the best variety of the pine timber, that which we designate as "Riga." The French dock-yards are supplied with mast-timber from the red pine of the Pyrenees and of the island of Corsica; but neither of these varieties of this timber is considered at all on an equality with that which is grown in the more northern parts of Europe. Indeed a low temperature of climate appears to be essential to the production of superior fir timber. The firs on the northern sides of hills and mountains, in all temperate climates, thrive better than those growing on the southern exposure, and even the timber on the northern side of an exposed fir tree is far superior to that on its southern side.

Yellow pine, the *Pinus Strobus*, which is imported from Canada, is the principal timber now available for large masts and yards, and is therefore very generally used both in the royal and the mercantile navies. It has neither the flexibility nor the elasticity of the red pine, nor is it so durable, but it is much lighter. Its great recommendations are its large size and its comparatively small cost. Sticks of this timber run from sixteen to twenty-seven or twenty-eight inches in diameter; and for bowsprits they are sometimes received in the royal yards as large as twenty-nine and thirty inches in diameter; but sticks of these large diameters are becoming very scarce. To Mr Cradock of Portsmouth dock-yard, a member of the late School of Naval Architecture, we are indebted for the following information as to the more extensive application of this species of fir for spars of all sizes in the American navy than in our own. In June of the year 1837, he surveyed the mast and spars of the American frigate Independence, then lying at Spithead. "They were generally as large, and in some instances the spars were larger, than those of the Britannia, a British first rate; and the whole of them, without any exception, were made of yellow-pine timber. Her topgallant-masts were about twenty feet longer than those of the Britannia, and yet were only of the same diameter, while those of the Britannia are made of Riga hand-masts. The topmasts were of the same length and diameter as those of the Britannia, which are made of Virginia red pine; the topsail-yards were three feet longer, and were yet only one inch more in diameter than those of the Britannia, which of course are made of Riga; and so on with the other spars. This proves, that the yellow-pine timber may be safely used if necessary for all masting purposes, with a very little increase in the diameter of the spars made from it, and with thicker battens on the yards."

The yellow-pine timber grows also in Great Britain, where it was first introduced by an earl of Weymouth, and thence is called the Weymouth pine; but it does not appear to thrive in this climate.

Scotish and Norwegian spruce spars, *Pinus Abies*, are very generally used in the mercantile navy for yards and topmasts, and also in the royal navy for the smaller description of spars and boats' masts. They are tough, close-grained, and elastic, but are very full of large knots; and care is therefore required in selecting them. The timber also is soft and far from durable, it having very little appearance of resin. The Norwegian spruce grows frequently to a large size.

Cedar, *Pinus Cedrus*, would be among the most valuable of all timber trees, were it sufficiently common to be available for building purposes. It is almost indestructible from time, and no insects will ever attack it. It thrives well in this climate, but hitherto has only been planted either as an object of curiosity or of ornament. It requires a more generous soil than any other of the tribe of pines, and is considered to be a timber of very slow growth. Pitch-pine is also a very valuable timber for building purposes, but it is too heavy for spars.

Fir sticks, the Riga hand-masts especially, are very liable to have serious defects in them, which it is often impossible to discover until the stick is worked. They are technically called upsets. The grain appears to be partly separated, so that a shaving from the stick at that place would bend to a sharp angle at the upset, as if partly broken. There always appears to be a greater or less accumulation of the turpentine about the injury, as if it had originally exuded at the wound, and become congealed around it. These defects are most frequently found in the smaller sticks, those especially that are more resinous and knotty than others; and they sometimes are so numerous as to extend, at very short distances apart, for a great portion of the length of the stick. Mr Cradock, who has long superintended the mast-making at Portsmouth dock-yard, considers them to be the effect of violent winds on the more exposed trees of a forest. He founds this opinion on the facts that they are most common in the most flexible timber; that they are not perceived in sticks of large diameter; and that in the firs of little flexibility, as the yellow pine, they are seldom or never found; although the sticks of this fir, from being cut in every variety of direction, to form the components of made-masts, are more searched than any other. The cowdee, a New Zealand timber, lately introduced both in the royal and mercantile navies, is, he says, much subject to this defect; and he has observed it once in a poon topmast. The defect seldom or never appears in the outer layers of the timber, but only after some of these have been removed by the axe, and the older timber laid bare of the sap-wood.

The sap-wood in all fir timber is useless, and very generally there is a large proportion of it in comparison to the quantity of heart-wood. It is rather a curious fact, that there appears to be a difference between the pines and the generality of the hard-wood timber in this, that a small proportion of sap-wood in fir is indicative of the inferiority of the timber. Thus the red pine of Scotland has fewer layers of sap-wood than either the red pine of Canada or of the Baltic. As a general remark, it may be stated, that the greater the quantity of sap-wood there is about a tree of any description of fir timber, the better will be the quality of the spine, which is the technical name given to the mature wood.

The cowdee, which is now largely imported into this country, is a close and even-grained timber, almost entirely free from knots. It grows to so large a size as to be available for the topmasts and other principal spars of the largest classes of vessels; but from its want of elasticity, and its liability to warp and rend, it is not so suitable for small conversions. It varies greatly in its quality, even so much as often to be of different colours, grain, and texture, in the same stick. It is of about the same average weight as Virginia red pine

Larch timber, *Pinus Larix*, formerly unknown in Great Britain, has, within the last century, been very extensively planted. The first plantations of it were made on the vast estates of the duke of Atholl, in the Highlands of Scotland. The following account, which is extracted from Knowles on Preserving the Navy, was, as the author of that work states, furnished to him by the late duke, and it contains, consequently, the results of the longest experience as to the growth of larch timber in Britain which can be obtained. The account is interesting, because plantations of larch are becoming very numerous, as they are found to be very profitable. The returns from a larch plantation during the time the trees are arriving at their full growth, are estimated to be at least double what they would have been from an equal plantation of any other timber. " Seedlings of larch were probably first brought into Scotland in the year 1738, by Mr Menzies; but it has been asserted by some, that they were introduced into that part of this country in 1734, by Lord Kames. Some were left at Dunkeld, and some at Blair Athole, by the former gentleman; and being exotic plants, were placed by the gardeners in greenhouses. Not thriving in those situations, they were planted in the pleasure-grounds, where they grew luxuriantly. When the present duke succeeded to the titles and estates (in 1774), there was a considerable number of trees in a thriving state; and on a general survey of his estates in 1783, there were found to be 900 Scotish acres of plantation, 600 of which were of larch; since which time his grace has planted extensively every year, and in the spring of 1820, 10,820 Scotish, or about 12,984 English acres, were covered with trees. The different species were, of

	Scotch Acres.
Oak	800
Scotish firs	1,500
Spruce firs	500
Mixed plantations in the pleasure-grounds	200
Birch	200
Larch	7,620
	10,820

" The larch thrives in very exposed situations. The lower range of the Grampian Hills, which extends to Dunkeld, are at an altitude there of from 1000 to 1700 feet above the level of the sea. The larch trees are planted as high as 1200 feet up these hills, and grow exceedingly well; a situation where the hardy Scotish firs cannot rear their heads. The spruce fir, however, thrives equally well as the larch on high and exposed hills. The growth of the larch trees is very rapid, and Scotish fir of the same age will measure only half the quantity; and so much is the wood esteemed in Scotland, that while the former is worth 2s. 6d. per cubic foot, the latter brings only 1s. 3d. The following account of a larch tree, planted in the year 1738, and measured February 1819, will give some notion of its growth.

Above the ground,	1 ft.		2 ft.		3 ft.		4 ft.		5 ft.		6 ft.		10 ft.		20 ft.		30 ft.		40 ft.		50 ft.		60 ft.		70 ft.		75 ft.

" The top was fifteen feet in height, making the whole height ninety feet; and the tree measured 300 feet, or six loads, in cubical contents. The white and red larch trees are those chiefly planted. The duke has made trial of the black or American, and also of the Russian larch, but has found that they do not thrive well. The timber in question has been used for many years in Scotland for almost all local purposes, such as posts, rails, mill-wheels, fishing and ferry-boats; and in all these situations has been found to be very durable. The author has seen part of a ferry-boat twenty-three years old, which remained very sound, and the iron nails driven into it as perfect as when they first came from the forge. This perhaps was occasioned by their being constantly covered with an insoluble varnish (the Venice turpentine of the shops), with which the larch abounds. The duke of Atholl has recently built a vessel of 10 tons wholly of larch, the necessary knees and crooks being formed from the roots of the trees; the lower masts and boats are also of that wood, the topmasts and yards of spruce firs grown upon his estates. One of the qualities of larch for building merchant-ships, is its great lightness, a cubic foot weighing, when seasoned (which it does rapidly), only thirty-four pounds. Although it is not so strong as many sorts of wood, it has great resilience. Cabinet-work of great beauty has been made from larch; it polishes well, and when seasoned is not found to warp or shrink. In addition to its other properties, it is slow of combustion, and is said to let shot through without splintering. A most important fact in agriculture has arisen from planting larch trees on rocky ground; the vegetable compost formed thereon by the falling of the leaves has been the cause of producing herbage for feeding cattle, and made that land which on the average did not formerly bring more than 8d. or 9d. per acre, now to be worth from 12s to 14s. per acre annually."

Larch timber, although so generally planted, and so generally thriving, requires considerable attention in the selection of proper soil for it. It is very subject to a heart-rot, which seizes on the roots, and rapidly proceeds up the centre of the stem of the plant, which swells considerably for several feet above the surface of the ground. Larch cannot bear a cold, damp soil, or any stagnation of water, or even the moisture of the rich vegetable moulds. Nor will it thrive in the light sandy soils; for although it dislikes marshy stagnant waters, its roots require to be preserved from the droughts of summer. Sandy and gravelly soils, if situated so as to receive from declivities the moisture percolating through them, will produce excellent larch timber; as will also the sides of rocky hills and mountains, in which no moisture can stagnate, and into the fissures and clefts of which the roots easily penetrate, and find ample nourishment. Larch trees attain to a very great height. In some of the public buildings of Venice, there are said to be single-pieced beams of larch which are 120 feet in length. It must be very durable, for it is almost the only wood which was used in the palaces and public buildings of that city. Larch is imported from Canada under two names, hackmatack and tamarack; at least the timbers bearing those names have every appearance of being identical with the Scotish larch.

On the Measurement of Timber.

Timber is bought and sold by solid measure, according to the number of cubic feet in the tree or log. The measurement of timber is therefore the operation by which the cubic contents are determined; that is, the multiplying together the three dimensions, or the mean length, the breadth, and the depth of each log. If the log should vary much in size in different parts, then the length, breadth, and depth of each of these parts must be multiplied together, and the contents of the log will be the sum of the products. When the log tapers, a mean breadth or depth is taken; the object in every case being to attain the most correct approximation to the contents of the log. In measuring rough logs, it is however usual to gird the log at the measuring place with a string, and then, folding the string into four equal parts, to assume this fourth part of the girth to be one side of the square area at the measuring place; which area, when multiplied by the length, will give the solid contents of the log. The arithmetical operation, simple as it is, is universally superseded by the more simple and far more correct plan of referring to published tables of contents, calculated for every foot in length of a log, and every quarter of an inch in the side of the square. Those most generally used for this purpose are in Hoppus's Practical Measurer.

In measuring standing timber, the length is taken as high as the tree will measure twenty-four inches in circumference, less than which measurement is not considered as timber. At half this height, the measurement for the mean girth of the timber in the stem of the tree is taken; one fourth of this girth is assumed to be the side of the equivalent square area. The buyer has in general the option of choosing any spot between the but-end and the half-height of the stem as the girding place. All branches, as far as they measure twenty-four inches in girth, are measured in with the tree as timber. An allowance, which varies according to circumstances, is generally deducted for the bark. In oak it is from about one tenth to one twelfth of the circumference at the girding place; in other sorts of timber it is less. In all, however, this allowance depends much upon special agreement.

It is usual to speak of timber by the load, which means fifty cubic feet of squared timber, or forty cubic feet of rough timber. A load of plank is dependent upon its thickness. Thus it will require 200 square feet of three-inch plank to make the load of fifty cubic feet; therefore the load of plank is the number of square feet of its respective thickness, which is necessary to make the load of fifty cubic feet. Deals are measured, according to their thickness and lengths, by the hundred, reckoning 120 to the hundred.

The practice of receiving and measuring timber for the use of the royal navy is more specific and strict in its detail than that which has been described; and as the customs of the public service in this branch of commerce must greatly influence the timber market, we shall proceed to give an outline of them.

Rough oak timber must be so hewn or squared, that at each measuring place the width of the surface or square shall not be less than one fourth the diameter of the piece at the place where the measurement is to be taken. The lengths for measurement are regulated by the several stops or joggles. Each piece of timber is measured for contents, by calliper measurements, as far as the spine[1] will hold twelve inches in diameter; and no tops are received excepting the spire and one other limb, remaining on the piece, and admitting of being converted with it. These limbs are only measured as far as they will hold twelve inches in diameter, unless the timber will convert as compass timber, in which case it is measured as far as it will hold nine inches in diameter.

Rough elm timber is measured in the same manner as the oak, excepting that the piece is measured as far as it will hold nine inches in diameter.

Sided timber, which may be defined as the rough log with two and opposite slabs sawn from it, is measured according to the following conditions. The term "siding" is synonymous with thickness, and the term "moulding" with breadth. It must measure at least twelve inches in parallel thickness. The moulding at the but-end must not exceed the siding by more than one half. The moulding at the middle of the length must not exceed the siding by more than one fourth, nor by less than one eighth; and the moulding at the top-end must not exceed the siding by more than one eighth, nor be less than the siding. The piece must be fairly tapered from the but-end to the middle of the length, and must not have more than four inches in the two wanes taken together on either side; that is to say, if there be but one wane,[1] that wane shall not exceed four inches. The piece must be so sided, that between the wanes, at half its length, there shall not be less than the siding with one eighth in addition, and the pane at the top-end must not be less than two thirds the pane at the middle of the length. The piece is measured for contents as far as it holds between the wanes three fourths of its siding. It must be so hewn the moulding way, that the surface of the square shall not be less than one fourth the diameter of the piece at that place, and this dimension must be set off previously to the diameter for measurement being taken. No but-length is allowed, but the timber is measured for contents at the middle of the length. If any piece of timber has length beyond the prescribed proportion of pane, and which is really convertible with the piece, it is received at a reduction of price. Timber having five inches or more of naturally grown rounding in any twelve feet or less of its length, is denominated compass timber.

---

[1] Spine is the technical term used to designate the perfect wood.

Timber of certain sidings must have at least certain proportionate lengths. These are as follow:

Siding.			Length.	
20	inches to	19½	must be at least	24 feet.
19	....	18½	....	22 ...
18	....	17½	....	20 ...
17	....	16½	....	18 ...
16	....	15½	....	16 ...
15	....	14½	....	14 ...
14	....	12	....	12 ...
12	....	10	....	10 ...

Compass oak timber is measured in the same manner as straight timber, with the exception that its moulding must not exceed its siding less than one fifth of that siding; and that the moulding at the but-end is to be measured as large as it will hold without more than four inches on the two wanes on either side taken together.

Thick-stuff is a name used to designate all planks beyond a certain arbitrarily assumed thickness, which is now four and a half inches and upwards, to ten inches inclusive. All below four and a half inches in thickness is called plank. It must be cut straight and of a parallel thickness, and the breadth for measurement, which is taken at half the length of the piece, must not exceed nineteen inches nor be less than twelve inches clear of sap. This breadth, at the middle of the length, is measured by taking in half the wanes, thus, , provided the breadth clear of the sap is within two inches of the breadth at which the piece is received. No thick-stuff can be received of less length than twenty-three feet, at which length it must measure nine inches clear of the sap; and all extra length, as far as it measures nine inches between the sap, is measured into the contents.

The rules for measuring thick-stuff and plank vary slightly, in order to accord with the growth of the sort of timber from which they are converted. For example, in the case of Lorraine oak thick-stuff, the minimum length is twenty-four feet; the measurement for breadth, which must not exceed eighteen inches, nor be less than fourteen inches, is taken at eight feet from the but-end of the piece. The piece must be square edged from end to end, and must measure nine inches at the top-end clear of sap on the most sappy side. English elm thick-stuff of five inches and four and a half inches in thickness, must not be less than fourteen inches broad in the middle of the length, nor less than twelve inches broad at the top-end clear of shakes and dead sap. The planks must average twenty-six feet in length, and no plank may be of less length than twenty-three feet. North American rock elm thick-stuff of five inches and four and a half inches in thickness, is received at twelve inches broad, clear of shakes and sap, of the average length of twenty-eight feet, but none shorter than twenty-four feet in length.

English oak plank of four inches thick must be at least twenty-two feet, and of three inches thick at least twenty feet in length. The breadth between the sap at those lengths must be seven inches, and the plank is measured as far as it holds six inches clear of sap. The breadth for measurement, which is taken at half the length of the piece, and clear of sap, must not be less than nine inches for the four-inch plank, and eight inches for the three-inch plank. This is taking in half the wanes, provided the breadth clear of sap be within two inches of the breadth at which the piece is received.

Dantzig oak plank of four and a half and four inches thick is to mete at thirty-two feet long, with a minimum length of twenty-four feet. It is to be from twelve to fifteen inches broad, and cut square edged its whole length. Plank of three and a half and three inches thick is to mete at twenty-eight feet long, with a minimum length of twenty-four feet, and to be from twelve to fourteen inches broad. Lorraine plank must be square edged from end to end. No plank of four inches in thickness is to be less than twenty-four feet in length, or more than sixteen inches or less than thirteen inches in breadth, at seven feet from the but-end. The length is to be measured for superficial contents as far as the plank runs eight inches in breadth, clear of sap on the most sappy side. For three-inch plank, the minimum length is twenty feet. The breadth at six feet from the but must not exceed sixteen inches, nor be less than twelve inches; and the length is to be measured for superficial contents, as far as the plank runs seven inches in breadth, clear of sap on the most sappy side. The sap on the two edges taken together on either side of this plank, after the edge is squared, must not exceed one inch; that is to say, if there be no sap on one edge, that on the other edge must not exceed one inch.

Fir timber received for general purposes is measured for its size at the middle of its length, and the size for measurement must be the mean of the sizes taken at the but and top, and the spine must be seen on the four sides from end to end of the piece. The red-pine timber, whether from the north of Europe or from Virginia, is not received of less length than eighteen feet, nor less in diameter than eleven inches. The Canada red-pine timber, which must be felled above Montreal, must not be of less length than twenty feet. The North American yellow pine must be at least twenty feet in length, and sixteen inches square. That which is received for the cheeks of made-masts is required to run as high in dimensions as sixty-three feet in length, and eighteen inches square at the measuring place.

Fir that is received especially for mast-making is required to be of certain proportionate dimensions. It is divided into two sorts, inch-masts and hand-masts. The inch-masts are designated according to the number of inches they measure in diameter at a measuring place called the partners, after they have been chopped on each square, so as to show spine; and their length must be nine feet more than three times the number of feet which they have inches in diameter. The distance of the partners from the but-end is in a given ratio to the whole ngth of the stick. Between the partners and the top-d certain measuring places are determined, at each of ich places, called "quarters," the diameter of the stick ist be in a given proportion to the diameter at the rtners; and all these conditions must be fulfilled before e stick can be received at the number of inches first as-ned as the diameter at the partners. If the sticks are ended for yards, the measuring place is at the slings, in e middle of the length, and the stick is measured from at point towards each end, the quarters being set off each y. If the sticks are intended for bowsprits, the given ameter is at the bed, and the quarters are set off towards ch end.

---

[1] Wane is the technical term used to designate the hypothenuse of an angular portion of timber which is wanting to complete the rectangular boundary of a log; while pane is the term applied to the side of the log between the wanes.

All these proportions for masts, yards, and bowsprits, e determined from tables which have been drawn out the purpose, and framed to suit the peculiarities of the owth of the various sorts of timber to be applied to these ferent uses.

Hand-masts are measured in their round state, accordig to the number of hands they are in circumference at e but, the hand being four inches. Their length must eighteen feet more than three times the number of feet at they are hands in circumference, and the top-end ist measure in circumference two thirds of the measurent of the but. Sticks which measure less than six hands e received under the general name of spars, and are denated as cant, barling, boom, middling, and small spars, cording as they measure above five, four, three, two, or e hand respectively.

On the Woods of India.

The following account of woods, the growth of our possions in the East Indies, is compiled from a series of rerts with which the writer of this article was favoured, rough the enlightened liberality of the Court of Directors the Honourable East India Company, and also from a per in the Asiatic Annual Register, written by Daniel mbert, Esq., which accompanied those reports. The rerts were made to the honourable court by their surveyor shipping in Bengal, John Millingar Seppings, Esq., a n of the late able surveyor of the royal navy, Sir Rort Seppings. The account embodies all those points in e reports which contain information consistent with the rpose of this article; and, as nearly as has been possible such a compilation, in order to insure correctness of inrmation, the language of the reports has been adhered to. e report of the experiments made by Captain H. C. ker has been given entire, as it would not admit of connsation; but in order to economize space, only the mean sults of the experiments have been printed; and the mber of experiments of which the given results are a ean, has been inserted in the table.

We have also been enabled, through the great kindness a friend, to enrich this article by a most valuable tabur series of original observations on the effect which seaning produces on almost every species of timber that has en treated of in the course of the foregoing remarks: which are appended some most interesting and judious observations and deductions by the author of the ble, Mr Bennett, of her majesty's dock-yard at Portsuth, a member of the late School of Naval Architecture.

The woods used in India for ship-building are, teak, ul, sissoo, jarrol, poon, and toon. Teak is the most rable among these timbers, but it varies very much in ality. There are two kinds of the Malabar teak, the rthern and southern; the first is far superior in point of rability, but is the most difficult to procure. The Malar teak is classed at Bombay as follows. No. 1, Northern, rved timber, which is brought a distance from Bombay from 130 to 140 miles; No. 2, Southern, Calicut teak; No. 3, Northern Pattey, or straight timber, used for small vessels and boats; No. 4, Bassein, or curved timber.

The great length of time which several vessels built of Malabar teak have lasted (from thirty to fifty years, in some particular instances nearly a century) has established the prime Malabar northern teak as the most valuable timber in the world for ship-building. It is, however, like every kind of wood, liable to early decay, if not properly or gradually seasoned, by exposure to a moderate current of air after being felled. Malabar teak is so seldom imported into Calcutta, from the expense of bringing it round Ceylon, and on account of the distance, that it may be said never to be used there for ship-building.

Pegu and Moulmein teak is extensively used by the ship-builders of the Hooghly, and is the only description of teak timber imported in any quantity to the Calcutta markets. It is brought in a half-wrought state, the logs or planks being squared. Pegu and Moulmein teak is a coarse, porous, open-grained wood, when compared with Malabar teak. It is not a timber which can be depended upon, particularly that which is of a pale-brown colour, which frequently goes very rapidly to decay. It is also of such a mixed quality, and the importation to Calcutta is so limited, that it is frequently difficult to select sufficient prime dark timber out of all the cargoes to build a ship of 200 tons burthen. Its weight, when moderately seasoned, may on an average be stated to be forty-two pounds per cubic foot, while the weight of Malabar teak on an average is from forty-five to fifty-two pounds per cubic foot. The forests of Tonga and Irrawaddy supply the whole of the Pegu teak. That of the Tonga forests is of the best quality, the country being high, and not flooded during the rainy season; whereas the forests of the Irrawaddy are always in a swampy state, and are part of the year covered with water sufficient to allow of the trees being floated from where they are felled. The Birmans are in the habit of tapping the teak trees, particularly those which are straight grown, to extract a varnish or oil, which is highly prized by them, and used chiefly for protecting their pagodas or temples from the weather, for which purpose it is very effectual. These edifices are built entirely of untapt teak, as the Birmans consider the timber to be much injured, both in its strength and its durability, by being deprived of this oil. The principal parts of these temples are sunk in the ground, and although so fixed, the timber remains perfectly sound, notwithstanding many of them have stood nearly a century.

The importation of teak from Moulmein and the Tenasserim coast has only taken place since the Birman war. Prior to that period, Calcutta was supplied almost exclusively from Rangoon, but only with straight teak. The Moulmein market first supplied crooked teak timbers, which sold at such prices as to induce the Rangoon merchants also to send crooked timber from thence. The quantity, however, is so very limited, that the greatest difficulty is at present experienced upon the Hooghly in completing vessels from 100 to 400 tons entirely of teak.

Inferior as the Pegu and Moulmein teak is in quality when compared with the Bombay teak, it is preferable either to the saul or the sissoo, which has been brought to Calcutta within the last fifteen years, and which will be presently noticed. The accounts of the forests of Pegu and Tenasserim are, that they are inexhaustible, and, if encouraged and properly worked, would supply timber of the largest size, and in sufficient quantity to meet the whole demand of the royal yards of Britain. In the batches of teak brought from the Tenasserim coast, a species of dark-coloured teak, approaching to black, may be noticed, which appears to be a superior description of timber. It is very tough, with the grain close and irregular. It is said to be brought down from the forests mixed with the common or brown teak. The following useful information as to the expense of both workmanship and material was obtained, in October 1832, from Captain Forzar, who was engaged in the Moulmein timber trade.

"The head Birmah carpenter, Mistry, offered to supply and trim teak timbers all round for a ship of 400 tons, at four rupees each; or to execute the whole of the work, as it regards the supply of carpenters, for 10,000 Sicca rupees, including joiners' work for the hull, and the masts, yards, &c."

"The price of teak crooks at Moulmein was,
1st sort large, to side about 12 to 15 in. 7 rup. each.
2d ditto middling, ditto 11 to 8 in. 3 to 5 rup. each."

"The 'Cashmere Merchant' cargo (imported into Calcutta) cost at Moulmein in 1832,

From 15 feet to 18 feet in length.
1st sort large... 9 rupees each.
2d do. middling 6 ditto.
3d do. small..... 4 ditto.

"Boat timbers, to side from three to six inches, and from four to seven feet long, cost from twenty to twenty-five rupees per hundred."

The other kind of teak used in India for ship-building is the Java teak, of which considerable quantities were imported into Calcutta during the time the English governed that island. Of late years scarcely any has been imported. The Java teak is of a very superior quality, and, judging from the state of the vessels built of it, it is nearly if not quite equal to Malabar teak.

All descriptions of teak, if sound, free from defects and from sap-wood, are proof against the white ants; whereas all other descriptions of timber enumerated in this memorandum are liable to the attacks of these insects.

Saul is a hard heavy wood. It is imported from Behar, Oude, and the inexhaustible forests that skirt the hills which form the northern boundaries of Bengal and Behar. It is used extensively in all Calcutta ships, for the timbers, beams, &c. It is of two kinds, the Goruckpore and Morung; the first is a most inferior timber, and goes rapidly to decay. An intelligent gentleman long engaged in the timber trade of this country writes as follows. The forests situated to the east of the Coosey river, and to the west of the Teestan, produce the only good saul in India, which, like the elephant, deteriorates in quality the farther it is produced to the westward. The best timber is found at the foot of the hills, on a rocky ground. Sauls of large dimensions are now becoming exceedingly scarce, as the whole of the forests within a reasonable distance of the navigable streams are completely exhausted; and every good timber must now be conveyed by land-carriage a journey of two days. A great part of the natives, and all the Europeans (with the exception of one gentleman), have given up timber cutting altogether. The great superiority of Morung saul over that produced to the west of these forests appears to have been but a recent discovery in Calcutta, though always well known to the native boat-builders. That found to the west of the Coosey river, for instance, Goruckpore and Bogah, being of a soft spongy nature, but little better than Mango wood, is now driven out of the market. The prejudice existing against the smaller timbers (dakar), on the ground of immaturity, would be done away with were it known that every fine tree produces a large and a small timber, the bottom the chakar, the top the dakar.

Good saul is inferior to the very fine description of sissoo which was used in Calcutta-built ships about thirty years ago. The best description of saul, if well seasoned, may be classed, in point of durability, with the best sort of African timber, now so extensively used by the ship-builders of England. The greatest care is necessary in the selection of saul for immediate use, on account of its requiring a long time to season. It is very heavy, and will not answer for any part of a ship exposed to the sun, as it shrinks very much. Saul continues to be used for the frame, beams, shelf-pieces, breast-hooks, and inside planking, of ships built at Calcutta.

Sissoo may be classed of two kinds, the dark and the light coloured. The first grows in the forests of the same districts where the best saul is to be found; but it has become so very scarce for some years past, that it is now seldom or never brought to Calcutta, although scarcely thirty years have elapsed since the forests of the north-west districts of Behar, where the finest sissoo timber is produced, were pronounced to be almost inexhaustible. The other kind (the light) has been the only crooked timber of late years brought down the country for ship-building: it is decidedly an inferior sort of wood, very subject to the dry rot, and to the attack of white ants.

Jarrol is of two sorts, the red and the white. The red jarrol grows to a size fit for the largest ships, and may be obtained in any quantity near Chittagong; at which place several fine ships have been built, some of which are now running, although from fifteen to twenty-five years old. They were built of red jarrol timbers, with Pegu teak plank. Jarrol is very extensively used in Rangoon-built ships, but of a mixed and inferior sort. Comparing the superior sort of jarrol with the best kind of sissoo or saul, it must be considered an inferior wood in point of durability. White jarrol is very inferior, and never should be used in ship-building.

Poon is also of two kinds, the dark and the light. It is a wood that answers very well for masts, for which it is used; but it is perfectly unfit to be introduced into the hull, either as timbers or planks. The Malacca red poon is that of which masts and yards are made.

Toon should never be used for ship-building. It has however been introduced into several Cochin-built ships, and after five years has been found perfectly rotten. It is a porous open-grained wood; and the only use it can be applied to is for making furniture, for which it is extensively used in Calcutta.

Perhaps the best test of the durability of a Calcutta-built ship which can be cited, will be the Hastings of seventy-four guns, built there in 1818. The hull is composed of saul, sissoo, Pegu and Java teak, all of the best kind. So great was the expense incurred in the building of this ship, that when completed, the account, after giving credit for her freight, exhibited the cost of the hull for sca 11,63,754 Sicca rupees, or, ten rupees to the pound, L.116,375 sterling. It is usual in Calcutta-built ships to convert the frame, with the knees, breast-hooks, &c. from sissoo timber; the beams and inside planking being of saul, and the bottoms, wales, topsides, decks, keels, stem, and stern-posts, of the Pegu teak.

Results of a Series of Experiments on the Elasticity and transverse Strength of different kinds of Timber. By Captain H. C. Baker, Superintendent of Suspension Chain-Bridges in Bengal.

The experiments, of which the results[1] only are here recorded, were conducted, as nearly as circumstances admitted, with similar apparatus to that used by Mr Barlow, and described in his treatise on the strength and stress of timber.

---

[1] The great extent of these experiments precludes the possibility of printing the whole of the results. In this article we have therefore confined ourselves to the averages which Captain Baker has deduced from them, and have merely stated in addition, the number of separate experiments from which these averages were shown. The experiments were made between the years 1827 and 1834.

The specimens, many of them, were obtained from the Commissariat Timber Depôt; some very fine ones from the Cossipore Gun-Carriage Agency, and others were the produce of the Calcutta market. Those of three and two feet n length were, generally speaking, cut from the sound fragments of the larger specimens.

The central deflections of the seven and six feet specimens were usually noted immediately after the application of each fifty pounds of fresh load, at which time the set aken by each appeared more regular than after some interval had elapsed. The first deflections were commonly recorded with 150 pounds weight, in some cases with only fifty pounds. Sometimes the specimen was turned upon he trestles and subjected to two or more trials; and in a few instances the load was left suspended for many hours, deflections being noted at different intervals of time.

The depth of the neutral axis was occasionally observed, but this has been found to vary so little (being generally ve eighths of the depth) as to render its insertion in the able of little practical utility.

The direct cohesive strength of the wood having also been subjected to experiment, the calculation of it from Mr Barlow's formula has not been thought necessary; but he curious in such investigations are here presented with bundant materials for pursuing the inquiry.

It is much to be regretted, that from the circumstances nder which most of the specimens were obtained, so little ccurate information respecting the timber could be procured. The age, size, time of felling, and circumstances nder which the trees had been respectively placed subsequently to their being cut down, would all have materially nhanced the value of this statement of results to the man of research; but, unluckily, no such information was accessible. Indeed in few cases was it even precisely known from what part of the timber the specimen itself was cut out, or what number was off the same trunk. The year of importation, where known, has been however inserted.

The following were the woods experimented on. Saul[1] *Sharea Robusta Rox*). This timber is too well known to render a lengthened description of it requisite; but its value or building purposes does not yet seem to have been fully appreciated. The great mechanical resistance it affords in cases of strain, however applied, renders it unquestionably he most valuable of Indian timber yet generally known or engineering purposes. The regularity of its deflections is indeed such as to render calculations of the requisite scantling for any particular stress, at all times simple and ure.

The general appearance of its fracture beautifully illustrates Mr Barlow's theory of the axis of motion or rotation being centrically situated; the upper or compressed fibres being smooth as though cut with a sharp knife, those in a ate of tension so fine and intimately blended as to resemble those of hemp rope when violently torn asunder.

The saul of the Calcutta market is seldom above thirty et in length, but the trees grow to a much greater height. From the injudicious practice of squaring it after felling, s mean girth is only about six to seven feet, but must be naturally much greater.

Saul has lately been very successfully substituted for teak in many of the component parts of the gun-carriages, checks, beams, and transoms; poles and framing of gun and ammunition boxes; occasionally spokes, naves, and fellies. Its toughness in cases of percussion must obviously render it a much safer material than teak to be near in action. It has also been used for door and window panels. It however shrinks more, from its greater density.

To both the above woods, the teak (*Tectona grandis*), in point of strength and elasticity, is decidedly inferior. Its brittleness renders it indeed rather hazardous to stand near the specimens when they are subjected to heavy strain, as the pieces, sometimes several of them, fly with considerable impetus in different directions.

A reference to the tables will show, that of a great number of specimens tried, three only, 80, 81, 88, of which only the mean result is given in this abridged table, see (1), at all approximate in results to those of Mr Barlow. The mean of my experiments is about 2·078, of Mr Barlow's 2·462, a number which exceeds that of the saul tried by me. Mr Barlow's specimens must therefore have been vastly superior to any in common use throughout India, for the comparative superiority of saul in point of strength is, I believe, indisputable.

The teak grows to a great height, seventy to eighty feet and more, but cannot be easily obtained good of that size, the heart being frequently very much decayed. It is a durable wood when exposed, and is not subject to the depredations of white ants until it has been very long in use. The uses to which teak is applied are too generally known to render much remark necessary; planking, boxes, panelling, doors, windows, venetians, furniture, beams of houses, are amongst the most common.

Sissooh (*Dalbergia Sissooh Rox*) in structure somewhat resembles the fine species of teak, but it is tougher and more elastic. The sissooh grows to the height of about thirty feet, but it is generally rather crooked, and therefore not so well adapted for beams. Sissooh is said to get harder with age.

It is by the natives employed for house-furniture, beams, cheeks; spokes, naves, and fellies of wheels; keels and frames of boats, blocks, printing presses; and generally in all work where crooked timber is required.

Jarrol (red) is a fine even wood in structure, and grows to great size in the Chittagong district; but that brought to the Calcutta market is too small to be of much use except for picture-frames and other similar purposes.

The Chittagong forests are said to be nearly cleared of the best or thorny species of jarrol; the others are of little value. It is considered a treacherous wood in ship-building.

In the following tables, it is necessary to bear in recollection that the letters represent the following qualities.

l. The length in inches.
a. The breadth or thickness.
d. The depth.
W. The breaking weight.
Δ. The last deflection.
W. Greatest weight whilst the elasticity continued unimpaired.
δ. Deflection ditto ditto.

---

[1] The saul and sissoo are obtained from the forests north of the Ganges line, between the 25th and 31st degrees of north latitude, and 74th and 88th degrees of east longitude, but chiefly from the tract lying north of Purneah and Goruckpore.

TABLE I.

Mean Results of a Series of Experiments on the Elasticity and Transverse Strength of different kinds of Timber grown in India. Made by Captain H. C. Baker, Superintendent of Suspension Chain-Bridges in Bengal.

Names of the Woods, and Dimensions of the Specimens.	Probable Date of Importation.	Number of Expcriments of which the Mean Results are given.	Specific Gravity.	Greatest weight and Deflection while the Elasticity remained perfect.		Breaking Weight in Pounds.	Ultimate Deflection in Inches.	Value of u from the Formula $U = \frac{l^2}{d\Delta}$.	Value of E from the Formula $E = \frac{l^3 W}{ad^3\delta}$.	Value of S from the Formula $S = \frac{lW}{4ad^2}$.
				Weight in Pounds.	Deflection in Inches.					
MORUNG SAUL.										
In specimens eighty-four inches long, two inches square, and seventy-two inches between the supports.

In order to make this valuable series of mean results as useful as possible, we have formed a similar Table from the mean results of the experiments made by Professor Barlow, and published by him in his work on the Strength of Timber. The two Tables taken together form a most interesting and perfect series of results.

TABLE II.

Mean Results of Experiments on the Elasticity and Strength of Timber, selected from Her Majesty's Dock-yard at Woolwich. Made by Professor Barlow.

Names of the Woods, and Dimensions of the Specimens.	Number of Experiments of which the Mean Results are given.	Specific Gravity.	Greatest Weight and Deflection while the Elasticity remained perfect.		Breaking Weight in Pounds.	Ultimate Deflection in Inches.	Value of U from the Formula $U = \frac{l^2}{d\,\Delta}$.	Value of E from the Formula $E = \frac{l^3\,W}{ad^3\delta}$.	Value of S from the Formula $S = \frac{lW}{4\,ad^2}$.
			Weight in Pounds.	Deflection in Inches.

On the Woods of British Guiana.

In Table III., which is the classification of timber adopted by the Committee of Lloyd's Register Book of British Shipping, there are two sorts mentioned as timber of the first quality, which are yet little known in this country in private building yards, and not at all in our public establishments. These are greenheart and morra. They are both the produce of British Guiana, a colony that will in all probability ere long be a chief source from which this country will draw her supplies of naval timber. The territories of the colony have never yet been clearly defined. Its extent has been variously stated, by some as not much exceeding 12,000 square miles, by others as extending over an area of 76,000 square miles. It is situated almost immediately under the equator, and has consequently the vigorous and luxuriant vegetation inherent to such regions. The forests of the interior are said to be of immense extent, and abounding in valuable timber trees. Among these are, the morra, which nearly resembles in appearance the best African oak; the simiri, or locust, a wood well known in England; and the siperi, or greenheart, so called from a peculiar green tinge which the timber has when cut with a tool. There are many other valuable timber trees, both for building and for ornamental work; but these perhaps are the most important to notice here.

The morra may be obtained easily to square twenty inches, and the logs run from thirty to fifty feet in length. It is said not to be susceptible of dry rot; but there can hardly yet be sufficient experience of it when combined in the masses of timber to be found in large ships, to establish this important point as indisputable. If it be as similar in its qualities as it is in its appearance to African oak, it certainly can claim no exemption from the attack of dry rot. The trees grow to a great height; and although the trunks are generally straight, the branches afford good compass timber.

But the most important timber produce of British Guiana is the greenheart. It is a hard close-grained wood, having, like teak, an oily feel to the touch. Its specific gravity is about equal to that of African oak, but it is decidedly superior to it in strength, toughness, and durability. These, however, are not its chief advantages: its great value consists in its being completely exempt from the attacks of worms. It is on this account used in Demerara for sluice-gates, piles, and all marine engineering works which would be exposed to their ravages. Experiments of a most conclusive nature as to its really resisting these insects have been made in this country. The port of Liverpool is much infested with worms, and the wood-work of the docks there is constantly destroyed by them. Clows of greenheart timber have now been down upwards of seven years at the west entrance of the Brunswick half-tide basin, and are as yet untouched; while experience has proved that clows of other timber in the same situation would have been destroyed in less than half that time.

This is a most important quality, and renders this timber invaluable for marine engineering works. It is imported in logs of from twelve to sixteen inches square, and from twenty to forty feet in length. It is exceedingly hard, and difficult to work as planking, although latterly some colonial vessels have been planked with it. There is another Guianian timber, the siruaballi, of a softer texture, and much used for planking, as it is also said to be able to resist the ravages of the worm.

TABLE III.

A Table exhibiting the different descriptions of Timber, of good quality, to be used in the Timbering, Outside and Inside Planking, of Ships, as the same will be applicable to the several terms of Years appointed for Ships to remain on the First Description of the First Class. From Lloyd's Register of British and Foreign Shipping for 1840–41.

Parts of a Vessel.	First Class. Twelve Years.	First Class. Ten Years.	First Class. Nine Years.	First Class. Eight Years.	First Class. Seven Years.	First Class. Six Years.	First Class. Five Years.	First Class. Four Years.	Parts of a Vessel.
Floors	English, African, Live oak East India teak Morung saul Greenheart Morra	Live oak and red cedar alternately Adriatic, Spanish, French oak South American or New South Wales hard wood	Other foreign white oak and red cedar		English ash Sound second-hand English or African oak or teak	English beech Larch Hackmatack	Baltic fir Red pine Black birch Foreign elm or ash Hardwood of good quality	White spruce	Frame
First futtocks		Live oak and red cedar alternately Adriatic, Spanish, French oak South American hard wood	Other foreign white oak below the light water-mark Red cedar		Other foreign oak above light water-mark Sound second-hand English or African oak or teak	English ash Larch Hackmatack			
Second futtocks		Live oak and red cedar alternately	Adriatic, Spanish, French oak South American hard wood Red cedar		Other foreign white oak	Larch Hackmatack Sound second hand English or African oak, or teak	Baltic fir Red pine	Elm Ash Black birch White spruce	
Third futtocks and top-timbers			Adriatic, Spanish, French oak South American or New South Wales hard wood Red cedar			Larch Hackmatack Pitch-pine Sound second hand English or African oak, or teak		Yellow pine Elm Ash Black birch White spruce	
Stem and stern post	English, African, Live oak East India teak		Adriatic, Spanish, French oak South American hard wood Red cedar			Hackmatack Larch		Black birch	
Transoms, knight-heads, hawse timbers, apron						Larch Hackmatack Sound second-hand English or African oak, or teak	Baltic fir Red pine	Yellow pine Elm Ash Black birch White spruce	
Main keelson	English, African, Live oak East India teak Morung saul Greenheart Morra	Adriatic, Spanish, French oak South American, or New South Wales hard wood Red cedar	Other foreign white oak		Pitch-pine Larch	Baltic fir Red pine American rock elm Hackmatack	Ash	Yellow pine Black birch White spruce	Keelson Beams Hooks Knees
Beams, hooks, and knees		Adriatic, Spanish, French oak South American hard wood New South Wales do. and red cedar for beams only		Other foreign white oak	Pitch-pine Larch Knees of fir, pitch-pine, or spruce	Baltic fir Red pine Hackmatack Sound second-hand English or African oak, or teak	Foreign elm Ash		
Keel to first futtock heads	English, African, Live oak East India teak Red cedar Foreign white oak English, American elm Beech South American or any hard wood	Pitch pine Larch Black birch	Baltic fir Red pine			Hackmatack	Yellow pine White spruce		

First futtock heads, to light water-mark	English African oak Live East India teak Red cedar Foreign white oak South American or New South Wales hard wood	Pitch pine	Baltic fir Red pine Larch	American rock elm			Yellow pine Black birch	White spruce	Outward planking
Light water-mark to wales	English African oak Live East India teak Morung saul Red cedar Greenheart Morra	Adriatic Spanish oak French South American or New South Wales hard wood	Foreign white oak Pitch pine	Baltic fir Red pine Larch		American rock elm Hackmatack	Yellow pine		
Wales to black strakes	English African oak Live East India teak Greenheart Morra	Red cedar Morung saul	Adriatic Spanish oak French South American or New South Wales hard wood	Other foreign white oak Pitch pine	Baltic fir Red pine Larch	Hackmatack	Yellow pine American rock elm	White spruce Black birch	
Topsides	English African oak Live East India teak Red cedar Greenheart Morra	Pitch pine Morung saul		Other foreign white oak					
Sheer strakes and plank sheer	English African oak Live East India teak Greenheart Morra	Red cedar Morung saul			Larch	Baltic fir Pitch pine Red pine Hackmatack	American rock elm	White spruce Yellow pine Black birch	
Waterways	English African oak Live East India teak Red cedar Greenheart Morra Morung saul Baltic fir Pitch pine Red pine Larch	South American or New South Wales hard wood		Foreign white oak Hackmatack			Yellow pine American rock elm	White spruce Black birch	Waterways
Limber strake	English African Adriatic oak Spanish French East India teak Morung saul Red cedar South American or New South Wales hard wood	Other foreign white oak		Pitch pine	Baltic fir Red pine Larch	American rock elm Hackmatack	Yellow pine Black birch	White spruce	Inboard planking and shelf-pieces
Bilge planks									
Ceiling lower hold				Pitch pine Baltic fir Red pine Larch					
Ceiling between decks		Other foreign white oak Pitch pine		Baltic fir Red pine Larch					
Shelf-pieces	English African oak East India teak Morung saul Red cedar Greenheart Morra	Foreign white Adriatic Spanish oak French South American or New South Wales hard wood		Pitch pine Larch		Baltic fir Red pine American rock elm Hackmatack	Yellow pine	White spruce Black birch	
Clamps					Baltic fir Red pine	American rock elm Hackmatack			

In this Table it is to be understood that any timber which has been named for a specific use in a preceding class, may be used for a similar purpose in any succeeding class; and also, that wherever blank spaces are left, it is to be understood that for that appropriation the timber is to be as for the preceding class.

The Committee of Lloyd's Register Book permit the best Honduras mahogany to be used for all those purposes to which African timber is permitted to be applied by this Table; but they do not yet deem it expedient that it should be inserted in their Table, as, although disposed to think favourably of it, they consider sufficient evidence as to its durability has not been obtained.

TABLE IV.

Table shewing the Original Dimensions and Solid Contents of various Specimens of Wood; together with their Dimensions, Weight, and Capacity after certain intervals of time; also the Weight of a Cubic Foot when seasoned and when unseasoned. Compiled by James Bennett, Esq. of H. M. Dockyard at Portsmouth, and formerly a Student at the late School of Naval Architecture, from specimens collected by himself, and now first published.

No.	Species of Timber.	Dimensions in Inches.	Date when Weighed and Measured.	Weight.	Capacity in Cubic Inches.	Weight. of a Cubic Foot.	Remarks.	
				lbs. oz.		lbs. oz.		
1	English oak.	6×6×6 6×6×6	June 1835. Aug. 1840.	5 10½ 5 7¼	216·0 216·0	45 4 43 10	3d Futtock.	Taken out of the Marlborough, 74; built in 1807, and broken up in 1835. Since kept in a room in which there is often a fire.

117	Cowdie.	12×6×6 12×6×5·9	1822. Aug. 1840.	10 15 9 13	432·0 424·8	43 12 39 14½	From New Zealand.
118	Ditto.	12×6×6 12×5·9×5·87	1822. Aug. 1840.	9 9 8 7¼	432·0 415·2	38 4 35 2½	Ditto.
119	Cowdie.	6×6×6	Aug. 1840.	4 8¼	216·0	36 2	Top. Same tree; a seasoned stick.
120	Ditto.	6×6×6	Aug. 1840.	4 9½	216·0	36 12	But.
121	Ditto.	6×6×6	Aug. 1840.	4 13½	216·0	38 12	Top. Same tree. It had been immersed some years in salt water.
122	Ditto.	6×6×6	Aug. 1840.	5 4¼	216·0	42 4	But.
123	Canada yellow pine.	6×6×6	Aug. 1840.	3 3¼	216·0	25 10	Top. From a line-of-battle ship's main-yard; 12 or 14 years old.
124	Ditto.	6×6×6	Aug. 1840.	3 8½	216·0	26 2	But.
125	Ditto.	6×6×6	Aug. 1840.	3 3½	216·0	25 12	Top. From a store-yard; 12 years old.
126	Ditto.	6×6×6	Aug. 1840.	3 2¾	216·0	25 6	But.
127	Ditto.	6×6×6	Aug. 1840.	3 7¾	216·0	27 14	Top. From a ship of war's bowsprit; about 16 years old.
128	Ditto.	6×6×6	Aug. 1840.	4 6½	216·0	35 4	But.
129	Ditto.	6×6×6	Aug. 1840.	3 8½	216·0	28 4	Top. Partially seasoned.
130	Ditto.	6×6×6	Aug. 1840.	4 2	216·0	33 0	But.
131	Ditto.	6×6×6	Aug. 1840.	3 13¾	216·0	39 14	Top. Immersed in salt water; just taken out.
132	Ditto.	6×6×6	Aug. 1840.	3 13½	216·0	30 12	But.
133	Poon.	6×6×6	Aug. 1840.	4 2½	216·0	33 4	Top. From an old top-mast.
134	Ditto.	6×6×6	Aug. 1840.	4 1½	216·0	32 12	But.

Remarks.

"In the above table, the first weight of each specimen was taken within or shortly after one year of the felling of the tree. This is to be generally understood, unless otherwise expressed.

"Few authors agree as it respects the weight of various species of timber in a seasoned and in an unseasoned state. This diversity of opinion often arises from an indefinite use of the terms 'seasoned,' and 'unseasoned;' and we need not be surprised at these seeming contradictions, when we remember that many other words which denote the state or condition of bodies, are equally indeterminate. Thus, when we speak of heat and cold, light and darkness, moisture and dryness, we may naturally inquire what diminution of heat occasions cold, what decrease of light causes darkness, or what absence of moisture constitutes dryness. Hence, generally speaking, the word 'seasoned' implies a relative rather than an absolute state of the wood. To prevent as far as possible any ambiguity on the subject, the dates and circumstances under which the wood was placed are carefully recorded, by which means the reader may form his own conclusions respecting the gradations of weight at intervals of time varying from one to twenty years. It should be understood, that large masses of timber, even if placed in dry situations for many years, in buildings or ships, would have their specific gravity diminished if cut into small portions. This will be manifest, if the reader refers to those specimens in the table which were taken out of a ship of war, the Marlborough.

"It occasionally happens that the specific gravity of timber is increased instead of being decreased by seasoning. This occurs when the shrinkage diminishes in a greater ratio than the weight. See No. 75 and 78.

"Shrinkage rarely takes place in the direction of the length of timber; when it does so occur, it seems to arise from a want of uniformity in the direction of the grain; for instance, when the wood is 'curly' and knotty. Independently of the length, the greatest shrinkage is in a direction at right angles with the 'silver grain;' the least in the direction of the plane of the 'silver grain.' Hence, when the heart of the tree is in the middle of the wood, so that the silver grain radiates from the heart to the exterior, there is no greater tendency to shrinkage in the one than in the other direction.

"In those cases in which the specimens are known to be tops and buts of trees, they are so distinguished; otherwise they must be supposed to be indiscriminately taken from the top, but, or middle of the trees. It is a generally-received opinion, that the but of English and other oak is heavier than the top; still men of great eminence differ on this subject. The view of Du Hamel may probably partly account for these conflicting ideas. He asserts, that in healthy vigorous trees, the but is heavier than the top; but that in trees past their maturity and on the decline, the top is heavier than the but. Whatever deference may be due to this opinion, an analysis of the facts contained in our table will show, that another cause materially affects the condition of the question, which is the hygrometrical state of the specimens subjected to experiment; for it is an interesting fact, which will be presently verified, that the but of a tree may be of greater, of equal, or of less specific gravity than the top, according as each is more or less advanced to a state of seasoning.

"Among others, the following results are derived from the foregoing table.

"1st, The average weight of a cubic foot of unseasoned English oak, derived from twenty-seven specimens, viz. No. 9 to 35 inclusive, is 1000 oz., or 62 lbs. 8 oz.

"2d, From the same specimens the average weight of a cubic foot of English oak allowed to season during the space of from thirteen to twenty years is 45 lbs. 9 oz.

"3d, Among the above twenty-seven seasoned specimens, the average weight of those which were kept in a warm room, in which there was occasionally a fire, was 47 lbs. 6 oz. to the cubic foot; whereas those which were kept in a shed weighed only 44 lbs. 13 oz. to the cubic foot. This result seems to warrant the conclusion, that within certain limits artificial heat does not season wood so expeditiously as natural heat and ventilation. It should be however remarked, that the average original weight of the specimens kept in a warm room exceeded that of those kept in the shed; the former weighing 63 lbs. $4\frac{1}{2}$ oz. to the foot, while the latter weighed 62 lbs. 3 oz. to the foot. The difference, however, is too small to vitiate the conclusion just drawn.

"4th, From the specimens of English oak in which the tops and buts are distinguished, it appears that in seasoned oak the top is heavier than the but; the average weight of a cubic foot of each being respectively 48 lbs. $7\frac{3}{4}$ oz., and 44 lbs. 4 oz. On the contrary, in unseasoned oak the but is heavier than the top, the average weight of a cubic foot of each being respectively 64 lbs. 14 oz., and 62 lbs. $13\frac{1}{3}$ oz. It hence follows, that there must be a medium state of seasoning, in which the top and but are equally heavy.

"5th, From specimens No. 37 to 42, it appears that the average weight of a cubic foot of French oak is, seasoned 48 lbs. $0\frac{1}{4}$ oz., and unseasoned 68 lbs. 2 oz. These specimens not having been seasoned four years, are not to be considered as having arrived at their ultimate state. Nos. 47 and 48 were not cut out until August 1840, although the trees were felled in 1836. These, however, together with 49 and 50, serve to show the degree of seasoning of the solid log, as compared with the seasoning of No. 37 to 42, being the same kind of timber cut into small portions.

"Taking the five specimens, 37 to 41, it will be seen that, both in a seasoned and in an unseasoned state, the tops are, at least at present, heavier than the buts. Thus,—

	Average Weight of a Cubic Foot of French Oak.			
	Seasoned.		Unseasoned.	
	lbs.	oz.	lbs.	oz.
But............	46	$11\frac{1}{2}$	51	0
Top............	51	10	68	14

"A like result will be obtained by examining the weight of No. 47 to 50, in which the logs remained some years in an unconverted state.

"6th, From an analysis of specimens, 53 to 59, it appears that the weight of a cubic foot of Adriatic oak, allowed to season twenty years, is 48 lbs. $6\frac{1}{2}$ oz. The same specimens unseasoned weighed 65 lbs. $10\frac{3}{4}$ oz. to the cubic foot. As the tops and buts are not particularly distinguished, no conclusion can be drawn respecting their comparative weights.

"7th, The specimens of Italian and American white oak are not sufficiently numerous to draw conclusions from them. The top and but of the Italian oak, No. 60 and 61, after being felled six years, were the same weight.

"8th, From specimens 64 to 86, it appears that the weight of a cubic foot of African oak allowed to season from thirteen to twenty years, is 60 lbs. 3 oz. The same specimens unseasoned weighed 64 lbs. 1 oz. to the cubic foot.

"It further appears that, both in a seasoned and unseasoned state, the buts are heavier than the tops. Thus,—

	Average Weight of a Cubic Foot of African Oak.			
	Seasoned.		Unseasoned.	
	lbs.	oz.	lbs.	oz.
But............	62	$12\frac{3}{4}$	66	$8\frac{1}{2}$
Top............	58	4	62	0

"9th, The average weight of a cubic foot of teak, seasoned during the space of nineteen years, is 42 lbs. $2\frac{1}{4}$ oz., unseasoned 48 lbs. 11 oz. Moreover, in an unseasoned state the weight of the but exceeds that of the top; while in an unseasoned state the weight of the top exceeds that of the but. Thus,—

	Average Weight of a Cubic Foot of Teak.			
	Seasoned.		Unseasoned.	
	lbs.	oz.	lbs.	oz.
But............	42	$13\frac{1}{4}$	47	10
Top............	41	11	48	6

"10th, With respect to larch, cedar, Riga fir, and a few varieties of the pines, their weights may be seen by inspecting the table. But it was thought that the specimens were not sufficiently numerous to justify any general conclusion respecting their weights in different states of seasoning.

"11th, Of the Dantzig fir, the average weight of a cubic foot of the unseasoned specimens is 39 lbs. There are only two seasoned specimens recorded; their average weight to the cubic foot is 32 lbs. $9\frac{3}{4}$ oz.

"Of the unseasoned specimens, from No. 103 to 112, the average weight of the buts (39 lbs. $14\frac{3}{4}$ oz.) exceeds that of the tops (35 lbs. $15\frac{1}{2}$ oz.).

"12th, The specimens of cowdie are not sufficiently numerous to form a decided opinion respecting the weight of this wood. Omitting No. 121 and 122, which, when weighed, was still saturated with salt water, we find the average weight of a cubic foot of the seasoned timber to be 36 lbs. $15\frac{3}{4}$ oz.; while the mean weight of the two specimens No. 117 and 118, in their unseasoned state, is 41 lbs. to the cubic foot. The but exceeds the top in weight.

"13th, With respect to Canada yellow pine, there are no specimens recorded in the table in an unseasoned state.

"In taking an average weight of the seasoned specimens, No. 129 to 132 are neglected, inasmuch as two are 'partially seasoned,' and two were weighed shortly after being taken out of salt water. With this explanation, the average weight of seasoned yellow pine is 27 lbs. $10\frac{2}{3}$ oz. per cubic foot.

"Out of the five trees from which the ten specimens of yellow pine are cut, it appears that in three of the trees the buts are heavier than the tops, whereas in the remaining two the tops are heavier than the buts."

The following articles may be referred to for information on timber: HORTICULTURE, PLANTING, STRENGTH OF MATERIALS, and SHIP-BUILDING. Some of the most celebrated works which may be consulted, besides those already mentioned, are, Sir John Hill, M. D., on the Construction of Timber as explained by the Microscope; first published in 1770: the work of Forsyth on Fruit and Forest Trees, which is also of importance, as he was the first to treat on vegetable surgery: the Planter's Guide, by Sir Henry Steuart of Allanton: and especially the Arboretum et Fruticetum Britannicum, by J. C. Loudon, in eight volumes; one of the most scientific and important books published on the subject. There are many other works which may be advantageously read, but it would exceed our limits to enumerate them.

The concluding short table will give some idea of the immense consumption of timber incidental to our being a maritime power; and the estimate that each ton of our merchant shipping has consumed at the very least a load and a quarter of timber, will perhaps tend to diminish the surprise which may have been excited in the early part of the article, by the assertion that the demand for timber was fast outrunning the supply, and exhausting the forests.

TABLE V.

An Account of the Quantity and Description of Timber, Thick-stuff, Plank, and Deals, necessary to complete a Ship of War of each Class, with the exception of the fitting up of the Bulkheads of the Cabins, and the Accommodations for the Crew.

In this Table the contents of the "sided oak" and of the elm timber are expressed in sided contents, which are derived from the converted contents by assuming the converted contents to be to the sided contents as 2 to 5. The sided contents of the fir timber are derived from the converted contents by assuming them to be to each other as 4 to 3. The quantities of deals are expressed in "feet running" of the rough deals expended on the ships. (B. Z.)

TIMBUCTOO, an African city, situated on the banks of the Joliba or Niger, in 17° 40′ north latitude, and 2° 30′ west longitude, being nearly the very latitude in which Ptolemy placed the town which he calls Cuphæ; and it is very remarkable that the principal stream of the Niger, which passes to the south and to the eastward of Timbuctoo, is laid down by Ptolemy as passing in the same direction in regard to Cuphæ.

This town, which has long been the object of European research, is greatly reduced from the magnitude and importance which it attained under the Arabian and Mahommedan power when triumphant in Africa. It now contains only about 13,000 inhabitants; but these are much superior to the inhabitants of the other African towns. According to Sidi Hamed, it is built on a plain surrounded on all sides with hills except on the south, on which side the plain extends to the river. About ten or twelve miles to the south of Timbuctoo stands Cabra, which is its port on the Joliba. De Caillé describes the city and its environs as dreary and desolate; but this may be accounted for by the circumstance of his having visited it at the close of the dry season; for other travellers have described the adjacent country as verdant and fruitful. Timbuctoo may be regarded as the principal mart for this part of Africa. It is the great central point to which the commercial travellers from Algiers, Tripoli, Tunis, Egypt, &c. resort. The Moors resident in Timbuctoo receive consignments of merchandise from Adrar, Taffilet, Towat or Twat, Ardamas (Ghadames), Tripoli, &c.; and some of the shops are well stored with articles of European manufacture. The king or governor of Timbuctoo, who is a negro, is himself a merchant.

The city forms a sort of triangle, measuring about three miles in circumference. The streets are clean, and wide enough to allow three horsemen to pass abreast. It is principally inhabited by negroes of the Kissoor nation. The Moorish merchants, after having made what they consider a fortune, generally return to their own country to enjoy the fruits of their labours. Fire-wood is scarce, and the town is indifferently supplied with water, which is procured from reservoirs, which have been excavated to the depth of thirty-five or forty feet for the purpose of collecting the rain-water. The inhabitants are zealous Mahommedans. They are neat in their dress, and in the interior of their dwellings, but are represented to be very licentious in their manners. The Tooariks, a warlike nation spread over the Great Desert, render the inhabitants of this and the other towns their tributaries.

TIME, a succession of phenomena in the universe, or a mode of duration marked by certain periods or measures, chiefly by the motion and revolution of the sun.

TIME, in *Music*. See MUSIC.

TIMERYCOTTA, a town and fortress of Hindustan, in the Carnatic, district of Palnaud, seventy-seven miles S.S.E. from Hyderabad. Long. 79. 20. E. Lat. 16. 17. N.

TIMON the *Sceptic*, who is not to be confounded with Timon the *Misanthrope*, was a Phliasian, a disciple of Pyrrho, and lived in the time of Ptolemy Philadelphus. He took so little pains to invite disciples to his school, that it has been said of him, that as the Scythians shot flying, Timon gained pupils by running from them. He was fond of rural retirement, and was so much addicted to wine that he had a successful contest with several celebrated champions in drinking. Like Lucian, he wrote with sarcastic humour against the whole body of philosophers. The fragments of his satirical poem *Silli*, often quoted by the ancients, have been carefully collected by Stephanus in his *Poesis Philosophica*, and by Brunck in his *Analecta*. Timon lived to the age of ninety years.

TIMON, surnamed *Misanthropos*, or the *Man-hater*, was a famous Athenian, who lived about 420 B. C. He was one day asked, why he loved the young Alcibiades, while he detested all the rest of the human race; on which he replied, "It is because I foresee that he will be the ruin of the Athenians."

TIMOR, East, the largest and southernmost of the Molucca Isles, intersected by the ninth degree of south latitude, and extending obliquely in a north-east and south-east direction. In length it is 250 miles, and from thirty to sixty in breadth. It is mountainous in the interior, the ridge by which it is intersected rising as high as the Peak of Teneriffe; while the south-east shores are exceedingly low, and overrun with mangroves. Gold, washed down from the mountains, is said to be found in the streams; but the natives are represented as extremely jealous of the researches of Europeans; and a body of Dutch sent into the interior on an exploring expedition was cut off by them. The chief products of the island are sandal-wood and bees' wax. Another article of export is biche de mer or sea-slug, which is partly procured near the island, and partly fished on the coast of New Holland, and brought to this island for sale. The bread-fruit tree grows here in great luxuriance, as does also mountain rice. Sandal-wood, bees' wax, honey, and slaves, are exported; and rice, arrack, sugar, tea, coffee, betel-nut, and the manufactures of China, with some from India and Europe, are received in return. The Dutch established themselves in this island at Coepang in 1630. Their territory did not extend beyond four or five miles round Fort Concordia. During the war which terminated in 1801, the communication with Batavia was interrupted, and the town was taken by the English. When Captain Flinders visited the island in 1803, he saw only two European residents at Coepang, besides the soldiers and the governor. The original inhabitants retain the mountains of the interior, to which they have been driven by the Malays, who possess the sea-coast. Some attempts have been made by the Dutch to establish Christianity, but with little success, the inhabitants remaining mostly in their original ignorance. Long. of the extreme south-west point of Timor, 123. 29. E. Lat. 10. 22. S.

Timor Laut, an island in the Eastern Seas, about seventy miles long by twenty-five in average breadth. It is situated between the 7th and 8th degrees of south latitude, and the 132d and 133d of east longitude. Nothing further is known of it.

TIMOTHEUS, one of the most celebrated poet-musicians of antiquity, was born at Miletus, an Ionian city of Caria, 446 years B. C. He was contemporary with Philip of Macedon, and not only excelled in lyric and dithyrambic poetry, but in his performance upon the cithara. According to Pausanias, he perfected that instrument, by the addition of four new strings to the seven which it had before; though Suidas avers that it had nine before, and that Timotheus only added two, the tenth and eleventh. The account of Pausanias is confirmed in the famous decree against him, still extant, and preserved at full length in Boethius. Mr Stillingfleet has given an extract from it, in proof of the simplicity of the ancient Spartan music. The fact is mentioned in Athenæus; and Casaubon, in his notes upon that author, has inserted the whole original text from Boethius, with corrections. The following is a faithful translation of this extraordinary Spartan decree. "Whereas Timotheus the Milesian, coming to our city, has dishonoured our ancient music, and, despising the lyre of seven strings, has, by the introduction of a greater variety of notes, corrupted the ears of our youth; and by the number of his strings, and the novelty of his melody, has given to our music an effeminate and artificial dress, instead of the plain and orderly one in which it has hitherto appeared; rendering melody infamous, by composing in the chromatic instead of the enharmonic: the kings and the ephori have therefore resolved to pass a censure upon Timotheus for these things; and further, to oblige him to cut all the superfluous strings of his eleven, leaving only the seven tones, and to banish him from our city, that men may be warned for the future not to introduce into Sparta any unbecoming custom." The same story, as related in Athenæus, has this additional circumstance, that when the public executioner was on the point of fulfilling the sentence, by cutting off the new strings, Timotheus, perceiving a little statue in the same place, with a lyre in his hand of as many strings as that which had given the offence, and showing it to the judges, was acquitted. It appears from Suidas, that the poetical and musical compositions of Timotheus were very numerous, and of various kinds. He attributes to him nineteen nomes, or canticles, in hexameters; thirty-six proems, or preludes; eighteen dithyrambics; twenty-one hymns; the poem in praise of Diana; one panegyric; three tragedies, the Persians, Phinidas, and Laertes; to which must be added a fourth, mentioned by several ancient authors, called Niobe, without forgetting the poem on the birth of Bacchus. Stephanus of Byzantium makes him author of eighteen books of nomes, or airs, for the cithara, to 8000 verses; and of 1000 Προοίμια, or preludes, for the nomes of the flutes. Timotheus died in Macedonia, according to Suidas, at the age of ninety-seven; though the marbles, much better authority, say at ninety; and Stephanus of Byzantium fixes his death in the fourth year of the 105th Olympiad, two years before the birth of Alexander the Great. Hence it appears that this Timotheus was not the famous player on the flute so much esteemed by that prince, who was animated to such a degree by his performance as to seize his arms, and who employed him, as Athenæus informs us, together with the other great musicians of his time, at his nuptials. From an inattention to dates, and from forgetting that of these two musicians of the same name the one was a Milesian and the other a Theban, they have been hitherto often confounded.

TIMPANI (Ital.), kettle-drums. See Music.

Tindal.

TINDAL, Matthew, a well-known English writer, was the son of the Rev. John Tindal of Beer-Ferres in Devonshire, and was born about the year 1657. He studied at Lincoln College in Oxford, whence he removed to Exeter, and was afterwards elected fellow of All Souls. In 1685 he took the degree of LL.D. In the reign of James II. he declared himself a Roman Catholic, but soon renounced that religion. After the revolution he published several pamphlets in favour of government, and the liberty of the press. His principal works are theological and ecclesiastical, but some of them are more connected with his character as a civilian. One of these is "An Essay concerning the Law of Nations and the Rights of Sovereigns." Another consists of "Discourses on the Obedience to the Supreme Powers, and the Duty of Subjects in all Revolutions." His "Rights of the Christian Church asserted," exposed him to a violent contest with the high church clergy; and his treatise entitled "Christianity as old as the Creation," published in 1730, made much noise, and was answered by several writers, particularly by Dr Conybeare, Dr Foster, and Dr Chapman. Its tendency was evidently deistical. Dr Tindal retained his fellowship till his death, which took place at London on the 10th of August 1733. He left in manuscript a second volume of his "Christianity as old as the Creation," the preface to which has been published.

TINDAL, Nicholas, the nephew of Dr Tindal, was born in 1687, and educated at Exeter College, Oxford, where he took the degree of A.M. in 1713. He became a fellow of Trinity College, and obtained several pieces of preferment in the church. In 1738 he was appointed chaplain of Greenwich Hospital; and here he died on the 27th of June 1774, at the age of eighty-seven. He was the author or translator of several works, but is chiefly remembered for his translation and continuation of Rapin's History of England.

TINE, an island of Turkey, on the western side of the Archipelago, separated from Andros by a channel three quarters of a mile across. It is about ninety square miles in extent, and contains about 16,000 inhabitants, who cultivate the land with great care. It yields corn, pulse, cheese, and fruits; but the product which affords the greatest employment is the breeding of silk-worms and the winding of silk. Although naturally sterile and rocky, it is more productive than any of the islands in its vicinity. Long. 25. 14. E. Lat. 37. 50. N.

TINGANO, a small river on the eastern coast of Malacca, which falls into the sea of China. Long. 103. 9. E. Lat. 5. 27. N.

TINGI, a cluster of small islands in the Chinese Sea, near the eastern coast of Malacca. Long. 104. 21. E. Lat. 2. 23. N.

TINGORAN, a small island in the Chinese Sea, near the eastern coast of Malacca. Long. 103. 33. E. Lat. 4. 8. N.

TINGTCHEOU, a city of China, of the first rank, in the province of Fokien, situated among the mountains which separate it from Kiangsee. Long. 116. 4. E. Lat. 25. 48. N.

TINIAN, one of the Ladrone Islands, in the North Pacific Ocean, about forty-two miles in circumference, first discovered by a Manilla ship, which was cast away here in 1638. The author of Anson's Voyage gives a most pleasing and romantic description of this island, as found by the crew of the Centurion in the year 1742. Commodore Byron, who visited this island in 1762, gives a description in every respect the reverse of that of Anson. He found it overgrown with weeds, and forests impenetrable, owing to a thick growth of underwood; the climate moist and sultry, and extremely unhealthy, owing to the violent and incessant rains; in addition to which it is infested with musquitoes and other venomous insects, as well as centipedes and scorpions. Tinian was visited in 1767 by Wallis, in 1787 by Captain Portlock, in 1788 by Captain Sever, and afterwards by other navigators, who all confirm the account given of it by Commodore Byron.

TINNEVELLY, an extensive district of the south of India, in the province of the Carnatic, 150 miles in length by fifty in breadth, situated principally between the 8th and 10th degrees of north latitude, and occupying the south-east extremity of what is called the peninsula. It is bounded on the north by Madura and Marawas; on the south-east it is separated from Ceylon by the Gulf of Manaar; and on the west it is bounded by Travancore. It is, generally speaking, an open and level country, though it contains some woods and several hills, and is tolerably well cultivated thirty miles north of the town of Tinnevelly. It contains no ruins of magnitude; but is watered by many streams flowing from the western mountains, and in favourable seasons yields abundant crops of rice and cotton, the latter of an excellent quality. The chief towns are Tinnevelly, Tutecoria, Vypaur, Callacand, Natradacotta, and Coilpatam. Towards the southern and eastern extremities are many salt marshes. Owing to their low situations, an inundation some years ago broke into them from the sea, and did much mischief, rendering the soil unfit for cultivation. The population consists chiefly of Hindoos, who retain much of their primitive customs and manners. During the first wars in which the British were engaged in this country, it abounded with petty chiefs, called polygars, who were constantly quarrelling with each other, and plundering the country. They resided in fortresses in the midst of woods, where it was extremely difficult to follow them with a regular force. In this disorderly state the country continued till the year 1792, when it was taken possession of by the British, who reduced to obedience a number of their chieftains. When the war commenced in 1799 with Tippoo Sultan, those polygars took advantage of the absence of the army, and broke into rebellion. As soon as a sufficient number of troops could be spared, a large force was sent against them, and before 1803 they were all subdued; and this occasion was taken for disarming them, demolishing their forts and strongholds, and reducing them immediately to the civil authority of the Company. The rents were raised from 70,000 pagodas in 1803, to 569,315 pagodas, or to L.190,000.

TINNEVELLY, the capital of the above district, is situated about twenty-five miles east of a range of mountains, and is large and populous. On three sides it is surrounded by extensive rice-fields, and on the west by rocky ground. The situation is not healthy, owing to the exhalations from the fields. Long. 71. 1. E. Lat. 8. 48. N.

TINNING, the covering or lining any thing with melted tin, or tin reduced to a very fine leaf. Looking-glasses are foliated or tinned with plates of beaten tin, the whole extent of the glass. They are applied or fastened by means of quicksilver.

TINTERN, a village of the county of Monmouth, in the hundred of Ragland. It stands on the banks of the river Wye, in a most picturesque situation, about five miles above Chepstow. Tintern is much visited on account of the remains of its abbey, which present, in good preservation, a view of the ecclesiastical architecture of the twelfth century. It was founded for Cistertian monks in the year 1131, and the ruins of its church still show a most striking view of beauty and grandeur. Its appearance by moonlight is peculiarly enchanting. In 1831 the village contained 313 inhabitants, who are employed in making iron wire. The excursion by water on the Wye to this place is very pleasing, either from Monmouth or from Chepstow.

TIPERAH, an extensive district of Bengal, situated on the eastern side of the Brahmapootra or Megna river, and between the 22d and 24th degrees of north latitude. On the north it is bounded by Silhet and Dacca; on the south by Chittagong and the sea; on the west it has the river Megna; and on the east it is divided from Ava or the Birman dominions by mountains and impervious woods, abounding with wild elephants and other ferocious animals. It is estimated to contain about 7000 square miles; a considerable portion of it is wild and desolate, and thinly inhabited by the Kookies, a savage race. The eastern division is productive, yielding abundant crops of rice and cotton; and a quantity of salt is also manufactured on the sea-coast on account of government. It devolved to the British in 1765, along with the rest of Bengal. Population 750,000, in an equal proportion of Hindoos and Mahommedans.

TIPPERARY, an inland county in the province of Munster, in Ireland, is bounded on the north by Galway and King's counties; on the east by King's, Queen's, and Kilkenny; on the south by Waterford and Cork; and on the west by Cork, Limerick, and Clare. It extends from 52° 11′ to 53° 10′ north latitude, and from 7° 23′ to 8° 25′ west longitude; being about seventy miles in its greatest length, on a meridional line, from the confluence of the Lesser Brosna and Shannon, north, to the Knockmeledown Mountains, south, and forty miles from O'Brien's Bridge, on the Shannon, west, to Urlingford, east, and comprehending an area of 1583 square miles, or 1,013,173 acres, of which 819,618 are cultivated, 182,147 mountain and bog, and 11,328 under water. It ranks as the sixth county in Ireland as to its total extent, and the fourth as to its extent of cultivated land.

According to the statement of Ptolemy, this district was inhabited in the second century by the tribes of the Darini and Coriundi, but Whitaker attributes it to the Scoti. It was afterwards possessed by various native septs, the principal of which were those of O'Kennedy, O'Mulrian, O'Fogarty, O'Heffernan, O'Hickey, M'Egan, Everard, Mathew, and Woulfe. Subsequently to the year 1172, it was granted by Henry II., who obtained possession of it after several sanguinary contests, to Theobald Fitz-Walter, surnamed Butler, from the office which he held in the king's household. It was reduced to the form of an English county by King John in 1210, and in 1328 Edward III. erected it into a county palatine, in favour of the first earl of Ormond; and though that king shortly after re-assumed the regal prerogatives, they were regranted in 1337, and in 1372 confirmed, to James the son of Theobald, and his heirs male for ever. This grant affected only the lay lands of the county, those belonging to the church being a separate jurisdiction, with its own courts and officers, under the name of the county of the Cross of Tipperary. The county continued to be thus divided both in fact and name until after the restoration, when the grant of the regalities was not only confirmed to the duke of Ormond by Charles II., but extended over the whole of the county. The jurisdiction continued in the family till the attainder of the last duke of Ormond, in consequence of which the whole of the ducal property reverted to the crown, the palatinal rights were abolished, and the records belonging to it deposited in the king's courts of chancery and common pleas, where they still remain. The county suffered greatly during the civil wars of 1641, in the course of which the town of Clonmell, after a gallant resistance, obtained honourable terms from Cromwell, who conducted the siege in person.

The surface is much varied. To the south it rises into the range of the Knockmeledown Mountains, the highest summit of which is 2698 feet above sea level. North of these are the Galtees, the highest of which, Galtymore, rises to an elevation of 3008 feet. Proceeding still farther north, are the Slievenamanagh Mountains, 2582 feet high; the Keeper, 2265; Arragh, 1558; and a portion of the Devil's Bit, 1572; the remainder of which last-named range extends north-easterly, forming the line of demarcation between King's and Queen's counties. The rest of the county presents an undulating surface, seldom perfectly level, and in some parts rising into hills of some elevation, the most considerable of which are the Slieveardagh Hills, bordering Kilkenny county, and Slievenamuck, near the base of which the town of Tipperary is situate. The only large river that passes through the county is the Suir, which has its source in the last-named range of mountains, near Roscrea, and after flowing in a southern direction, by Templemore, Thurles, and Cahir, to Ardfinnan, takes a western course by Clonmell, and, passing through Carrick-on-Suir, enters the county of Waterford, and discharges itself into the Atlantic through the estuary of Waterford harbour. The Shannon forms part of the western boundary of the county, from its most northern point, at the junction of this river with the Lesser Brosna, through its expansion called Lough Derg, and thence to O'Brien's Bridge. The Lesser Brosna is the northern boundary from Parsonstown to the Shannon, and the Nore traverses a small portion of the north-east of the county. There are no lakes of any extent; three of small size, worthy of notice chiefly from their shape and romantic position, lie in the glens of the Galtees.

The mountains are mostly composed of clay-slate, surrounded by sandstone; those of Knockmeledown are also capped with horizontal strata of this latter mineral. The part of the Devil's Bit range which projects into the county is wholly sandstone, as are also the groups of the Galtees and Slievenamuck. The beds of the latter range horizontally, so as to furnish large quantities of excellent flags from the quarries there. Slates of good quality are raised in the district adjoining the southern extremity of Lough Derg, and carried in large quantities to various distant places by the Shannon navigation. There is also a very extensive and valuable slate-quarry near Clonmell, which enjoys equal facilities of transport by the Suir. In the east of the county, from Killenaub eastward, is a coal-field, generally considered to be an offset or continuation of that in Kilkenny and Queen's counties. The seams, which lie between strata of sandstone and shale, are in some cases single, in others double, and even treble. The thickness of those in the Coalbrook mines, which have been long worked, is from one to two feet. The produce of these works consists of one fourth coal and three fourths culm. The former is in considerable demand for manufacturing purposes, being highly esteemed on account of the large portion of pure carbon contained in it; the latter is equally so for making lime, and is also used for culinary purposes when wrought up into balls with clay. Ironstone, though found in large quantities in the Coalbrook works, is not applied to any profitable account. The village of Silvermines, on the northern side of the Keeper Mountains, derives its name from the mines of silver in its neighbourhood, which at a former period had been largely worked, as were copper-mines in the same neighbourhood; but both have been relinquished. Copper was also raised at Lackamore, near Newport, but with a similar result. Zinc, manganese, malachite, galena, and white lead, have been found in various places. The natural caves discovered in 1833 in a low limestone hill, near the southern base of the Galtee Mountains, and about midway between Cahir and Mitchelstown, present a peculiar feature in the geology of the county. They are entered by a passage sloping downwards, about 200 feet in length, which opens into a subterraneous chamber nearly eighty feet long and upwards of thirty at its greatest height; whence proceed other passages communicating with a number of interior caves of various sizes, that have obtained names chiefly from their discoverers, or from some peculiar resemblance, whether real or fanciful, to objects of general notoriety. Their roofs, sides, and floors are adorned with a great variety of stalactites of singular appearance, and in some parts there are small reservoirs of the purest water. The number of these apartments has not yet been accurately ascertained; nor has a detailed geological account of the interior yet appeared. They are generally known by the name of the Mitchelstown caves, from their vicinity to that town, and are objects of much care to Lord Kingsborough, on whose estate they were discovered. The level part of the county is chiefly limestone, constituting one extremity of the great field of that formation, which spreads over all the central portion of Ireland. Its most striking peculiarity is the rock of Cashel, consisting of a mass of limestone arranged in concentric strata, rising precipitously from the surrounding plain.

The soil in the plain country, and in the extended valleys, is a rich calcareous loam, capable of producing the finest crops with little aid from human industry. The town of Tipperary forms the centre of a tract of flat country lying between the Galtee and Slievenamanagh ranges, and extending from the county of Limerick westward to Golden and the Slieveardagh Hills in the opposite direction, which, from its extraordinary fertility, has been called the Golden Vale. Another tract of similar character, but not so extensive, lies in the northern baronies of Ormond. The soil on the hills and mountain sides is light and poor, partaking much of the character of the substrata of clay-slate and sandstone on which it rests. The southern extremity of the great Bog of Allen spreads itself into this county in its north-eastern quarter, from Roscrea to Holycross, not however in one continuous sheet, but in detached portions. It appears to have owed its origin to the obstructions in the channel of the Nore, a small portion of which skirts the county here. The whole of these detached portions of bog contains 35,000 acres, the most elevated part of their surface being about 400 feet above the sea, and therefore perfectly capable of drainage. The timber found here is chiefly fir, yew, and oak, the latter perfectly black, from the action of the iron in the bog-water, or the gallic acid in the tree. The substratum is universally limestone or gravel. In one of these bogs three growths of timber have been found lying under one another; the upper about five feet from the surface, the middle about two feet lower, and the third, which is always in a more or less decomposed state, near the gravelly bottom. The land in the neighbourhood of the bog tract is generally swampy, producing little but reeds and other aquatic vegetables. The sides of the valleys, watered by the streams that pass through the bog and marshes, throw up a good herbage without any artificial aid, except that of setting fire to the surface in the heat of summer. The heath and moss are thus destroyed, and scope is given to a spontaneous growth of grass, on which cattle feed eagerly in all seasons, but chiefly in summer, the cool and moist sward being peculiarly grateful to their feet. Several tracts near the margin of the bog have been reclaimed, and the process is extending, although slowly, owing to the obstructions arising from individual interests, to a general and effective system of drainage. There is little, if any, native timber; but plantations, sometimes very extensive, are to be seen around all the gentlemen's seats and the residences of the wealthier farmers. The growth of timber thus raised is as yet by no means sufficient to remove the appearance of bareness which the landscape, otherwise abounding in natural beauties, exhibits.

The progressive increase of the number of inhabitants appears from the following table of the population as taken at different periods.

Year.	Authority.	No.
1760	De Burgo	101,370
1792	Beaufort	169,000
1812	Parliamentary census	290,531
1821	Ditto	346,896
1831	Ditto	402,538

According to the latest of these returns, the population is to the entire surface as 1 to 2·517, and to that of the number of cultivated acres as 1 to 2·036. There is therefore a family of six individuals to every fifteen acres of the total surface, and to every twelve acres of cultivated land. According to the census taken by the commissioners of public instruction in 1834, which being calculated by dioceses, allows only an approximation to accuracy as compared with those calculated by counties, the total population amounted, in round numbers, to 413,000, of which 16,840 were of the established church, 660 Protestant dissenters, and the remaining 395,500 were Roman Catholics, who were then to the total Protestant population as twenty-three to one. The number of children receiving instruction in the public schools, according to returns made under the population act in 1821, the commission of education in 1824–6, and the latest return of the commission of national education, was,

Year.	Males.	Females.	Sex not ascertained.	Total.
1821	14,160	6,586		20,746
1824–6	29,941	12,188	547	33,676
1837	3,694	2,588		6,282

The return of 1824–6 is the only one in which the religious persuasion of the pupils is noticed. According to it the numbers were, members of the established church 2871, Protestant dissenters eighty-four, Roman Catholics 30,407, religion not ascertained 314, which gives an average of thirty Roman Catholics to one Protestant. In the same return the total number of schools is stated to be 657, of which forty-three, affording instruction to 2747 pupils, were maintained wholly by grants of public money; seventy-one, with 5256 pupils, by voluntary subscriptions; and the remaining 543, with 25,673 pupils, wholly by the fees of the pupils.

The county is divided into the eleven baronies of Clanwilliam, Eliogarty, Iffa and Offa East, Iffa and Offa West, Ikerrin, Kilnemanagh, Middlethird, Lower Ormond, Upper Ormond, and Slieveardagh, which are subdivided into 189 parishes, of which ninety-six were in the diocese of Cashel, twenty in that of Emly, thirty-two in Lismore, and forty-one in Killaloe. The cathedrals of the dioceses of Cashel and Emly are both within the county, in places from which the sees have received their names. The former, which retains the rank of a city, is still a place of some note; the latter, though said to be the ancient Imlagh, noted by Ptolemy as one of the three principal cities in the island, is now an inconsiderable village, with a population of 701 souls. Under a late order of council, the county has been divided into two ridings. It returned eight members to the Irish parliament, two for the county, and two for each of the boroughs of Cashel, Clonmell, and Fethard. The number was reduced to four by the act of union, which disfranchised the last-named borough, and deprived each of the others of one of its members. The constituency of the county, at several periods since the disfranchisement of the forty-shilling freeholders in 1829, is as follows:

Year.	L.50.	L.20.	L.10.	Total.
1831	2015	411	475	2901
1832				2360
1834				2369

The local government is under the control of a lord lieutenant, twenty-eight deputy-lieutenants, and 118 other magistrates, besides eight stipendiaries specially appointed, and receiving salaries from the crown; under whom is a constabulary force, which in 1836 consisted of twelve chief constables and 686 constables and subconstables, and, since the division of the county, of one county inspector, six subinspectors, seven head constables, and 351 constables and subconstables for the north riding, and one county inspector, seven subinspectors, ten head constables, and 391 constables and subconstables for the south. The county prison, at Clonmell, is ill adapted for carrying into effect the improvements now generally introduced into the prisons of Ireland. A prison for the north riding is at present building in Nenagh. The number of committals in 1839 was 2110, of whom 1164 were acquitted or liberated for want of prosecution, and 946 were convicted. Of this latter class, 256 were fined or liberated on securities, 608 imprisoned, seventy-three transported, and nine sentenced to death, of whom four were executed. Besides the convictions above stated, 583 were convicted before the magistrates at petty sessions for trivial offences, and 3889 for intoxication. The total number of convictions is to the population as one to sixty-three, and of convictions for capital or transportable offences as 1 to 5037. The county infirmary, fever hospital, and lunatic asylum, are also in Clonmell. The last-named institution maintains ninety-nine patients, fifty-five male and forty-one female. Of the cases there are, idiots four, epileptic one, curable maniacs sixty, incurable thirty-one; besides which there are in the Clonmell house of industry nineteen cases of idiocy and seven of epilepsy. The sites of the work-houses under the new poor-law act have been fixed at Carrick-on-Suir, Cashel, Clogheen, Clonmell, Nenagh, Roscrea, Thurles, and Tipperary.

The modes of agriculture are regulated by the character of the soil and the face of the country. Tillage prevails in the lowland districts, and is carried on with much spirit, and in general according to the most modern systems. The size of the farms is generally small, averaging at about fifty acres, and in many instances diminishing to eight or ten, in consequence of the subdivision of land among the under tenants. The rotation adopted on the rich lands in the Golden Vale, and in the almost equally fertile districts in the northern parts of the county, is, potatoes, wheat, and oats; in the lighter soils, as on the Slieveardagh Hills, and the mountain sides, on which the use of the plough is yearly encroaching on the ancient pasturages, as far up as the nature of the soil favours the exertion of agricultural industry, the crops are potatoes, barley or bere, and oats. In too many instances the repetition of the oat crop is continued until the land is completely exhausted, when it is allowed to rest until the renovating powers of nature clothe it with a new sward. Artificial grasses are much encouraged; clover of both kinds, rye and other grass-seeds, are sown, as are rape, vetches, and turnips. Flax is seldom to be seen but in detached patches, or along the head-lands of the corn-fields. Lime, and limestone gravel, the latter taken from the escars in the eastern parts of the county, are the principal manures. The fences are stone-walls, or mounds of earth eight or ten feet broad at the base, and tapering upwards to a considerable height, with a topping of furze or whitethorn. The latter plant is also employed as a ground fence in the best-regulated estates. Owing to the undulating character of the surface, drainage is less necessary. Where it is adopted, and especially in the pasture lands, a covered drain is used, which is so narrow, and sunk so low, as not to be injured by the pressure of the feet of the cattle on the surface sod. Agricultural instruments of the most approved construction are in use among the better classes of farmers, and machines for the abridgement of human labour are employed in many places. The rich low lands along the banks of the river are generally under meadow, and produce abundant crops of hay. The lands appropriated to pasture are used both as grazing and dairy farms. Butter, which is made to a great extent, finds a ready market at Clonmell, Waterford, and Limerick. The manufacture of cheese is almost unknown. The breed of Irish cows is still kept up, in consequence of the quantity of milk which they yield. They are sometimes reared without any mixture of other breeds, sometimes with a cross of the Holderness or Devon. The horses bred in the county are highly esteemed, and bring good prices. For agricultural purposes, asses and mules are much used by the small farmers, as being more hardy, and thriving on coarser food. The former of these are of larger size than those in other parts of the country. Swine are to be met with everywhere; they form an important part of the farming stock of the landholders, from the highest to the lowest, and are exported in great numbers to England. Sheep are less numerous, either because the quality of the soil is not well suited to them, or because the subdivision of the lands into small fields, and the want of substantial fences in the smaller farms, prevent their being much encouraged. Though a great deal has been latterly effected in the way of agricultural improvement in both its main branches of tillage and pasturage, much more is still required in order to draw forth all the capabilities with which the bountiful hand of nature has enriched this tract.

The manufacture of woollen cloth was formerly carried on to a great extent, particularly in the neighbourhood of Clonmell and Carrick, which were the two principal marts of the trade; but in consequence of the legislative arrangements made after the revolution, for the suppression of that branch of national industry in Ireland, it has declined so as now to be nearly extinct; a small trade in blankets, flannels, and a mixed light cloth called ratteens, being the only vestige of its existence. Many efforts have been made to introduce the linen manufacture as a substitute. Grants of implements and premiums were offered by the Irish linen board appointed to encourage and foster the manufacture. Much of the funds sent into the country from England during periods of famine were employed to turn the course of industry, particularly among the females, into this channel, but to no purpose. The culture of flax, as already stated, is but little attended to, the plant being raised in small quantities, and manufactured merely for domestic use, in which it is also more and more superseded every year by the increasing demand for cotton fabrics. There is a cotton factory at Clonmell. The staple manufacture of the county is that of flour, for which there are numerous mills. The abundant supply of the raw material from the rich valleys and champaign lands, and the numerous sites, with a great command of water-power on the many branch-streams that feed the main rivers, afford facilities of which due advantage has been taken; and the export of flour is consequently the main stimulus to industry, and a great source of internal wealth. Many plans have been devised to increase this wealth by increasing the facilities for transmitting agricultural produce throughout the country, and to the great marts. The generally level yet undulating surface of the land affords adequate scope for carrying on lines of inland navigation, and extending railway communications. Both have been subjects of consideration. A canal was projected to form a continuation of that already existing from Dublin to Monastereven. It was to proceed by Roscrea and Cashel to Carrick, whence there is a river-navigation to Waterford. Others of minor extent were projected to pass through the northern and western parts of the Shannon, which is navigable all along the verge of the county; but none has yet been undertaken. Several lines of railroad have also been latterly proposed. Besides others laid down by private engineers at the suggestion of individuals or intended joint-stock companies, the commissioners for inquiring into the expediency of introducing the system of railroads into Ireland, have suggested a line in continuation of that proposed to be carried from Dublin to Kilkenny, which, after passing Maryborough in Queen's county, is to enter Tipperary near Templemore, and to pass by Thurles to Holycross, whence one branch is to tend southwards by Cashel, Goldenbridge, Cahir, and Mitchelstown, to Cork, and the other along the southern base of the Slieve-Phelim Mountains, by Pallasgreine, to Limerick. These lines are laid down in the map lately published by the conductors of the trigonometrical survey of Ireland, but no steps have as yet been taken for their accomplishment. Several new lines of road have however been executed, some of which, being cut through the mountainous districts on the north-west of the country, have produced the double effect of facilitating the transmission of goods, and, what is of much greater importance, the improvement and welfare of the country, by throwing open a tract hitherto impassable for carriages, and consequently the almost inaccessible place of refuge for desperate characters of every description, who here set at defiance the laws, and made the place a centre from which to make inroads, on favourable opportunities, into the open country. One of the great lines of mail-coach roads to Cork passes through the county; and the intercourse for travellers unencumbered with much luggage has been increased in a great degree by the establishment of one-horse travelling cars, which ply between all the principal market-towns and places of resort. For this great improvement the county is indebted to the exertions of an intelligent foreigner, M. Bianconi, who devised and has carried on the system as a private speculation on his own account. In the county there are thirteen banking establishments, of which three are in Clonmell, two each in Nenagh, Roscrea, Thurles, and Tipperary, and one each in Carrick-on-Suir and Cashel.

The remains of antiquity are numerous, but, with few exceptions, not of a very remarkable character. There are two round towers, one at Cashel, the other at Roscrea, both in good preservation. Among the remains of ancient monastic buildings, many of which are still in existence, the most worthy of notice are those on the Rock of Cashel, consisting of the ancient cathedral, a fine Gothic structure, exhibiting a combination of the military with the ecclesiastical style of architecture; and Cormac's Chapel, a venerable building, with a fine groined roof, and having in the interior some very ancient paintings in fresco, and a number of statues supposed to represent the apostles. The remains of ancient castles are also numerons, as might be expected in a part of the country so often the seat of intestine wars. Several old fortresses are still kept in repair, and improved so as to form the residences of the proprietors of the surrounding lands. There is also a number of elegant mansions and villas belonging to the resident noblemen and gentry. The dwellings of the peasantry differ little from those in other agricultural districts, nor are there any very marked variations in their manners, dress, or mode of living. The lower classes have long been notorious for their spirit of lawless turbulence, which has been attributed, among other causes affecting the country in general, to the neglect of absentee landlords, and to the almost total want of communication through the mountainous districts. The latter of these has been considerably diminished within the last few years; and the projected commercial facilities designed by the railroads, if carried into execution, will tend to complete this desirable change.

The county town is Clonmell, on the Suir; a large and populous place, partly in this county and partly in Waterford, with a population of 17,838 souls. It is a parliamentary borough, returning one member, and one of the great marts for the agricultural produce of the county. It was also the seat of the woollen manufacture until its failure throughout Ireland, after which that of cotton has been introduced, but with partial success. Its chief channel of export is by the Suir to Waterford, by means of boats of fifty tons and under. One of its principal articles of export is butter, for the sale of which a large building has been erected. Brewing and distillation are extensively carried on here or in the vicinity. The public buildings are those usual in county towns; the parish church, a large old building; two Roman Catholic chapels, and other places of worship; a court-house, prison, public school-house, infirmaries, and the county lunatic asylum. Some vestiges of the ancient fortifications still remain. One of the four gates, which is still kept in repair, forms an ornamental entrance to the town on the western side. Since the division of the county into two ridings, Nenagh, the place appointed for holding the assizes in the north riding, has received some improvement. A prison is there in progress of erection. The population of this town amounts to 8446. Cashel, a city with a population now reduced to 6971 souls, was anciently the royal residence of the kings of Munster, the most celebrated of whom, Brian Boru, built its fortifications. It was also the seat of the archiepiscopal residence, and so continued until the see was reduced to a bishopric and united with those of Waterford and Lismore, under the provisions of the church temporalities act of 1833. The archbishop's palace is in this city. It has a small library, chiefly of theological works, attached to it. Cashel is also a parliamentary borough, returning one member. The other larger towns are Carrick-on-Suir, a place of some trade by means of its site on that navigable river. Population 9626. Thurles, the seat of the Roman Catholic see of Cashel, having in it the cathedral and the archiepiscopal residence, 7084; Tipperary, 6972; Roscrea, 5512; Cahir, 3408; Fethard, 3400; and Templemore, 2936. (C. P.)

TIPSTAFF, an officer who attends the judges with a kind of staff tipped with silver, and takes into his charge all prisoners who are committed or turned over at a judge's chambers.

TIPTON, a large village of the hundred of Offley in the county of Stafford, 127 miles from London. It has become a place of importance, from the extension of the potteries which are carried on there. The inhabitants amounted in 1821 to 11,546, and in 1831 to 14,951.

TIRAÑAS and TONADILLAS (*Spanish*) are Spanish national melodies in $\frac{3}{4}$ time, and of a moderate movement, sung with an accompaniment for the guitar only. The Spanish dance-tunes, such as the *Fandangos*, the *Boleros*, and the *Seguidillas*, formerly much in vogue in Spain, were played on the guitar, often accompanied by the voice, and by castanets. The *Bolero*, a modification of the *Seguidillas*, is said to have derived its name from a dancing-master of Murcia, named *Bolero*.

TIREH, a town of Anatolia, in Asia Minor, on the Meinder, which has some manufactures. It was besieged by Timor in 1402, when the inhabitants redeemed their lives by a sum of money. Thirty-two miles S. S. E. of Smyrna.

TIREY, one of the Hebrides Islands, situated in long. 6° 52′ W. and lat. 56° 32′ N. Its length is twelve miles, and its greatest breadth about four and a half miles; and it contains about 13,000 Scotch acres, of which nearly 4000 are considered as arable. Its nearest distance from Mull, at Kilninian, is fourteen miles, and from Iona eighteen miles. Tirey consists of gneiss, composed of hornblende, quartz, and felspar; but from the inconsiderable elevation of the rocks, the course of the beds cannot be stated. The marble wrought in the island is remarkable for the fineness of its quality. The island in its general surface is flat, and so low that it is scarcely elevated twenty feet above the high-water mark. There are no streams in it except two, which issue from two small lakes, one at its southern, and the other at its western side. Water is however easily procured, by digging within a few feet of the surface. The soil of Tirey is in general light, and consists of calcareous sand mixed with peat-earth, which, together with quartz, contains a large proportion of shells. These, with the constant and regular moisture which it derives from its climate, render the island remarkable for the richness of its natural pasturage. There is not a single tree in the island, and it is entirely destitute of fuel, even of peat-moss, so that the inhabitants have to supply themselves, at much personal risk, expense, and labour, with this necessary article, from the Island of Mull. They generally employ their capital in the rearing of black cattle; but the width of the ferries, and the risk and expense of freight, make a serious deduction from the value of their stock. Potatoes are cultivated to a great extent, and this has had a beneficial effect in the cultivation of much peat-land. Sheep have also been introduced with success. The population of the island is too great for its productiveness, and the inhabitants begin to feel the necessity of emigration. In 1831 they amounted to 4453.

TIRHOOT, an extensive district of Hindustan, province of Bahar, situated principally between the 27th and 28th degrees of north latitude. It is generally well cultivated, and productive of grain, sugar, indigo, tobacco, opium, and of late years has bred numbers of horses and cattle. Towards the northern frontier it possesses extensive forests, but unfortunately no rivers to float the timber to the Ganges. It came into the possession of the British in 1765. Its population is estimated at 2,000,000, in the proportion of three Hindoos to one Mahommedan.

TIRLEMONT, a city of the Netherlands, in the province of South Brabant and circle of Louvain. It has been fortified, but its walls are dilapidated. It stands on the river Geete, has a very fine market-place, and contains 8400 inhabitants, who carry on breweries and distilleries, and make some woollen cloths and hosiery. It is on the great road from Brussels to Liege. Long. 4. 48. E. Lat. 50. 49. N. A railroad from Brussels is nearly completed to this place, and is intended to proceed to Liege to join the Meuse.

TIROLESE (*Ital.*), a kind of waltz-tune, mingled with triplet passages, in $\frac{3}{4}$ time, and of a moderate movement. The Tyrolese songs have a similar melody, and are generally performed in a singular *falsetto* voice.

TITAN, in fabulous history, the son of Cœlus and Terra,

d the elder brother of Saturn, suffered the latter to enjoy
e crown, on condition that he should bring up none of
s male issue, by which means the crown should at length
vert to him. But Jupiter being spared by the address of
hea, Saturn's wife, Titan and his children were so enraged
seeing their hopes frustrated, that they took up arms to
venge the injury; and not only defeated Saturn, but kept
m and his wife prisoners till he was delivered by Jupiter,
ho defeated the Titans; when from the blood of those
tans slain in the battle, proceeded serpents, scorpions,
d all venomous reptiles. Such is the account given by
e poets of this family of Grecian and Roman gods. From
e fragments of Sanchoniatho, however, and other ancient
iters, many learned men have inferred that the Titans
ere an early race of ambitious heroes, who laid the foun-
tion of that idolatry which quickly overspread the world;
d that by assuming the names of the luminaries of heaven,
ey contrived to get themselves everywhere adored as the
ii majorum gentium. That the word *Titan* signifies the
n, there can indeed be very little doubt. Every one
ows that such was its signification in the Æolic dialect;
d as it is evidently compounded of *Ti*, which in some
iental tongues signifies *bright* or *clear*, and *Tan*, which
gnifies a *country*, or the *earth*, it may be safely concluded
at *Titan* was the name of the sun before the word was
ported into Greece. But the great question among an-
quaries is, of what country was that race which, assum-
g to themselves the names of the heavenly bodies, intro-
uced into the world that species of idolatry which is known
y the appellation of *Hero-worship?* Pezron, in "L'Antiquité
es Tems," maintains that the Titans were a family of Sacæ
Scythians, who made their first appearance beyond Media
d Mount Imaus, in the upper regions of Asia; that they
ere the descendants of Gomer the son of Japheth and
randson of Noah; and that after conquering a great part
f the world, upon entering Upper Phrygia, they quitted
eir ancient name of Gomerians or Cimmerians, and as-
med that of Titans. All this, he says, happened before
e birth of Abraham and the foundation of the Assyrian
onarchy; and he avers that Uranus, their second prince
the order of succession, conquered Thrace, Greece, the
land of Crete, and a great part of Europe. Uranus was
cceeded by Saturn, and Saturn by Jupiter, who flour-
hed, he says, 300 years before Moses, and divided his vast
mpire between himself, his brother Pluto, and his cousin-
erman Atlas, who was called Telamon. For the truth of
is genealogy of the Titans, Pezron appeals to the most
pproved Greek historians; but, unluckily for his hypothe-
is, these writers have not a single sentence by which it can
e fairly supported. Others, taking the fragment of San-
honiatho's Phœnician History for their guide, have suppos-
d the Titans to have been the descendants of Ham. Of this
pinion were Bishop Cumberland and some other writers.

TITHES, in ecclesiastical law, are defined to be the
enth part of the increase yearly arising and renewing from
he profits of lands, the stock upon lands, and the personal
ndustry of the inhabitants; the first species being usually
alled *predial*, as of corn, grass, hops, and wood; the se-
ond *mixed*, as of wool, milk, pigs, &c., consisting of na-
ural products, but nurtured and preserved in part by the
are of man; and of these the tenth must be paid in gross;
e third *personal*, as of manual occupations, trades, fish-
ries, and the like; and of these only the tenth part of the
lear gains and profits is due. We cannot precisely ascer-
ain the time when tithes were first introduced into this
ountry. Possibly they were contemporary with the plant-
ng of Christianity among the Saxons by Augustin the
onk, about the end of the sixth century. But the first
ention of them which we have met with in any written
English law, is in a constitutional decree, made in a synod
held A. D. 786, by which the payment of tithes in general is strongly enjoined. This canon or decree, which at first bound not the laity, was effectually confirmed by two kingdoms of the heptarchy, in their convention of estates, respectively consisting of the kings of Mercia and Northumberland, the bishops, dukes, senators, and people. This was a few years later than the time when Charlemagne established the payment of them in France, and made that famous division of them into four parts; one to maintain the edifice of the church, the second to support the poor, the third the bishop, and the fourth the parochial clergy. The next authentic mention of them is in the *Fœdus Edwardi et Guthruni*, or the laws agreed upon between King Guthrun the Dane, and Alfred and his son Edward the Elder, successive kings of England, about the year 900. This was a kind of treaty between those monarchs, which may be found at large among the Anglo-Saxon laws. As Guthrun was a pagan, it was necessary to provide for the subsistence of the Christian clergy under his dominion; and accordingly we find the payment of tithes not only enjoined, but a penalty added upon non-observance. This law was seconded by the laws of Athelstan, about the year 930.

TITHING (*Tithinga*, from the Saxon, *Theothunge*, *i. e. Decuria*), a number or company of ten men, with their families, knit together in a kind of society, and all bound to the king for the peaceable behaviour of each other. Anciently no man was suffered to abide in England above forty days, unless he were enrolled in some tithing. One of the principal inhabitants of the tithing was annually appointed to preside over the rest, being called the *tithing-man*, the head-borough, and in some countries the borseholder, or borough's ealder, being supposed the discreetest man in the borough, town, or tithing. The distribution of England into tithings and hundreds is ascribed to King Alfred.

TITIANO VECELLI, the most universal genius for painting of all the Lombard school, and the best colourist of all the moderns, was born at Cadore, in the province of Friuli, in the state of Venice, in 1477, or in 1480 according to Vasari and Sandrart. His parents sent him at ten years of age to one of his uncles at Venice, who, finding that he had an inclination to painting, put him to the school of Giovanni Bellino. But as soon as Titian had seen the works of Giorgione, whose manner appeared to him abundantly more elegant and less constrained than that of Bellino, he determined to quit the style to which he had so long been accustomed, and to pursue the other, that recommended itself to him by having more force, more relief, more nature, and more truth. Some authors affirm that he placed himself as a disciple with Giorgione, yet others only say that he cultivated an intimacy with him; but it is undoubtedly certain that he studied with that great master, that he learned his method of blending and uniting the colours, and practised his manner so effectually that several of the paintings of Titian were taken for the performances of Giorgione; and his success then inspired that artist with an invincible jealousy of Titian, which broke off their connection for ever after.

The reputation of Titian rose continually; every new work contributed to extend his fame through all Europe, and he was considered as the principal ornament of the age in which he flourished. And yet Sandrart observes, that amidst all his applause and constant employment at Venice, his income and fortune were inconsiderable; and that he was more remarkable for the extensiveness of his talents, than for the affluence of his circumstances. But when his merit was made known to the emperor Charles V., that monarch knew how to set a just value on his superior abilities; he enriched him by repeated bounties, allowed him a considerable pension, conferred on him the honour of knighthood, and, what was still more, honoured him with his friendship. Titian painted the portrait of that benefactor

Title || Titus Vespasianus.

several times; and it is recorded by Sandrart, that one day while the emperor was sitting for his picture, a pencil happening to drop from the painter, he stooped, took it up, and returned it; obligingly answering to the modest apology of the artist (who blushed at the condescension of so great a monarch), that the merit of a Titian was worthy of the attendance of an emperor.

It cannot be truly affirmed that Titian equalled in design the great masters of the Roman school; but he always took care to dispose his figures in such attitudes as showed the most beautiful parts of the body. His taste in designing men was not generally so correct or elegant as it appeared in his boys and female figures; but his colouring had all the look of real flesh; his figures breathe. He was not so bold as Giorgione, but in tenderness and delicacy he proved himself much superior to him and all other artists. The expression of the passions was not his excellence, though even in that respect many of his figures merited the justest commendation; but he always gave his figures an air of ease and dignity. His landscapes are universally allowed to be unequalled, whether we consider the forms of his trees, the grand ideas of nature which appear in his scenery, or his distances, which agreeably delude and delight the eye of every observer; and they are executed with a light, tender, and mellow pencil. He learned from nature the harmony of colours, and his tints seem astonishing, not only for their force, but their sweetness; and in that respect his colouring is accounted the standard of excellence to all professors of the art. He was of so happy a constitution, that he was never ill till the year 1576, when he died of the plague, at the age of ninety-six or ninety-nine. His disciples were Paulo Veronese, Giacomo Tintoret, Giacomo de Porte Bassano, and his sons.

TITLE, an appellation of dignity or rank given to princes and persons of distinction. Titles were not so common among the ancient Greeks or Romans as they are in modern times. Till the reign of Constantine, the title of *Illustrious* was never given except to those who were distinguished in arms or letters; but at length it became hereditary in the families of princes, and every son of a prince was illustrious. The title of *Highness* was formerly given only to kings. The kings of England before the reign of Henry VIII. were addressed by the title of *your Grace.* That monarch first assumed the title of *Highness*, and afterwards that of *Majesty.* The title of majesty was first given him by Francis I. in their interview in 1520. Charles V. was the first king of Spain who assumed the same title. Princes, nobles, and clergy, generally have one title derived from their territories and estates, and another derived from their rank, or from some other remarkable circumstance. The pope has the title of *Holiness.* A cardinal is saluted by the name of *Eminent*, or *most Eminent.* An archbishop, besides being named from his diocese, is called *his Grace* and *most Reverend.* A bishop is also distinguished by the name of his diocese, and has the title of *his Lordship* and *right Reverend.* Inferior clergymen are denominated *Reverend.*

TITULAR denotes a person invested with a title, in virtue of which he holds an office or benefice, whether he performs its functions or not.

TITUS VESPASIANUS, the Roman emperor, the son of Vespasian; of whom it is related, that not being able to recollect any good action which he had done on a certain day, he exclaimed, "I have lost a day!" He might truly be called the *father of his people;* and though Rome laboured under various public calamities during his reign, such was his equitable and mild administration, that he constantly preserved his popularity. He was a great lover of learning, and composed several poems. He reigned but two years; and it is thought Domitian, his brother, poisoned him, A. D. 81, aged forty-one.

TIVERTON, a town of the hundred of the same name, in the county of Devon, 163 miles from London. It stands on the river Exe, where the Leman joins that stream, and by the two the town is nearly surrounded. They are rapid streams, and well calculated for turning large machinery. The town was much enriched by its woollen trade; and since that has been on the decline, powerful engines have been framed for making lace, a trade that is carried on to a vast extent at present. There is a school founded by Richard Blundell, who was a clothier of this town, of great celebrity. It has four exhibitions or scholarships at Oxford, and the same number at Cambridge. The school-house is a very fine pile of building. Tiverton is a place of great antiquity, has been long incorporated, and now elects two members to the House of Commons. For municipal purposes, the town is divided into three wards, and is governed by a mayor, six aldermen, and seventeen councillors. There are markets on Tuesday and Saturday. The inhabitants amounted in 1821 to 8651, and in 1831 to 9766.

TIVOKEA, a low sandy island in the South Pacific Ocean, of an elliptical form, and eighteen miles in its longest diameter. Long. 144. 56. W. Lat. 14. 28. S.

TIVOLI, a city of the papal dominions, the capital of a district of the same name, on the river Teverone, on the side of a hill. It is the seat of a bishop, has a fine market-place, a cathedral, ten parish and fourteen conventual churches, with 5550 inhabitants, but is an old and ill-built place. It is, however, much visited on account of the cascades of the Teverone, which present most exciting groups of objects. Near to it are the remains of the consular road, the remains of the Villa Adriana, the ruins of the gate of the villa of Mæcenas, and those of the house of Quintilius Varus, with the temple of Vesta and the grotto of Neptune. Long. 13. 11. E. Lat. 41. 57. 49. N.

TIZE, a seaport of Persia, in the province of Mekran, once important, but now reduced to a miserable village of fifty or sixty huts. It is ten miles south from Churbar.

TJIDANEE, or TANGERANG, a river of the island of Java, which runs a northerly course, and falls into the Java Sea in the bay of Bantam.

TOBACCO. See NICOTIANA.

TOBACCO-Pipes, Manufacture of. The art of making tobacco pipes, or, as it is commonly called, *pipe-making*, though one of the simplest species of pottery, is sufficiently curious to merit description. The process may be divided into six stages; viz. 1. Beating or preparing the clay; 2. Rolling; 3. Moulding; 4. Trimming; 5. Drying; and, 6. Burning.

Preparation of the Clay.—The fine white clay employed by the pipe-makers is dug from the quarries in masses of about a cubic foot each. Before it can be used in the manufacture of tobacco-pipes, it must be reduced to the consistence of a tough paste. To effect this, after its outer surface has been cleared from dirt or dust, it is broken into small pieces about as large as a goose's egg, and thrown into a tub with such a quantity of soft water as experience has shown to be sufficient to bring it to the proper consistence. After lying till it has soaked up all the water, which usually requires from twelve to twenty-four hours, it is taken from the tub and laid on a strong wooden bench. Here it is beaten by a heavy four-square iron instrument, in such a manner as to cut it from one end to the other into very thin slices. It requires considerable address to perform this operation, and it is surprising how thin the workmen will sometimes cut the slices, and how equally they will thus divide the clay. This beating is continued, alternately folding up the clay and slicing it, till the whole is perfectly smooth. It is then ready for rolling.

Rolling.—The operation of rolling reduces the clay into pieces of a proper size and length for making pipes, and almost to their proper form. The roller sits at a bench with a smooth board before him, and holds in his hand another smooth board about eighteen inches long, four broad, and about half an inch thick, having one end rounded off on one side, so as to produce a corresponding hollow in the clay. He now takes a piece of the beaten clay, and rolls it out, first with his hands, and then with the board, till it acquire the form of a long slender cylinder, with one end considerably larger than the rest. This large end is to form the bole, and the cylinder the shank, of the future pipe. The pieces of clay thus formed are laid beside each other on a flat board, and are now ready for moulding.

Moulding.—This is the most complex operation, and requires the greatest number of instruments. The principal of these is the mould, which is composed of two long pieces of iron, formed so as to join together, and having their corresponding sides cut into the shape of half a tobacco-pipe, each piece being hollowed so as to form half a slender cylinder, with a larger cavity at the upper end, and at such an angle as it is intended the bole of the pipe shall make with the shank. Just above that part of each side of the mould which stands beyond what is intended to form the bole, there is a notch for admitting a knife to cut off the superfluous clay. To receive the united mould there is a vice, having at one end two upright posts, between which moves a long lever; and to this lever, near the posts, there is loosely attached a piece of iron ending below in a smooth conical head, capable of entering the large opening of the mould, but rather smaller than the opening, so that when forced down into it, a sufficient thickness of clay may be left between the cone and the sides of the mould, to form the bole of the pipe. One side of this vice is fixed, and the other moveable towards the former. The moveable side has attached to it an iron screw, with a very long lever as its handle; so that by turning the screw one way or the other, the moveable side of the vice may be forced nearer the fixed side, or suffered to return to its original position.

Besides these principal instruments, the moulder requires a slender steel wire, fixed in a handle at one end, and having its other extremity formed into a very small head; a saucer containing wool well impregnated with oil, and a small woollen or cotton brush.

When about to mould his pipes, he lays hold of the shank of one of the rolled pieces, and with great dexterity, which practice alone can teach, he passes up the oiled wire through its whole length, till he finds it arrived at the commencement of the larger extremity of the clay. This extremity he then bends to the proper angle, and having oiled the inside of each part of his mould, he lays the piece of clay, with the wire in it, into one part of the mould, and covers it with the other. He now puts the mould containing the clay into the vice, and with the left hand turning round the handle of the screw, so as to fix the mould firmly within the vice, he, with the right hand, presses down the lever with its conical head, and thus forms the cavity of the bole. He now withdraws the mould, cuts off with his knife the superfluous clay from the bole, opens the mould, takes out the pipe, and now only withdraws the wire. He then lays the moulded pipe on a flat board, in the same manner as the rolled pieces before described. The pipes thus moulded require to be trimmed, that is, to have the prominences rising from the joining of the mould, and other superfluous pieces of clay, taken off, so as to render the surface smooth and round.

Trimming.—The operation of trimming is generally performed by boys and girls, as it requires very little skill. The trimmer has before him a smooth block of wood, about the length of the pipe, and of considerable thickness, elevated a little at the remote end. He has also a thick piece of smooth iron, one edge of which has across it two or more semicylindrical grooves, capable of receiving half the shank of a pipe. Taking one of the rough moulded pipes, the trimmer carefully passes up the hollow of the shank a wire similar to that employed in moulding, and holding the pipe by the bole, while the shank lies before him on the wooden block, he pares off with a blunt knife all the excrescences of clay, both from the shank and bole, and rubs the former, while lying on the block, with the grooved part of his iron, so as to render it as smooth as possible. He now cuts off the ragged piece at the extremity of the shank, withdraws the wire, and lays the pipe on the drying frame. One great object of the trimmer is to see that the pipe is completely perforated, which he discovers by blowing through it; and if he finds the hole choked up, he must open it by pushing the wire as far as possible. If this does not succeed, he breaks the pipe, as useless.

Drying.—The pipe has now received all the work that can be bestowed on it by the maker, previously to its being burned; but as the exposing of it to heat while soft and pliable would make it crack, it is necessary that it be properly dried. For this purpose, a frame is prepared, composed of three or four long pieces of wood, fastened to two end-pieces in such a manner that the middle of the frame shall be the lowest, to give the shanks of the pipes that curve which they generally possess. After being trimmed, the pipes are laid beside each other in this concave frame, with their boles hanging down over the edges of the frame, and their shanks bending within its hollow. In this position they are exposed to the air till they are dry and firm. They are then ready for burning or baking.

Burning.—For burning or baking the pipes, there is to be prepared a kiln of a simple but peculiar construction. It is built in the form of a cylinder, close at the bottom and on the sides, and open at the top. Below the bottom is a grate for receiving the fuel, and round the sides are constructed vertical or spiral flues, opening at the top, and communicating below with the grate. The sides of the furnace on its interior are pretty thin, and are formed of a cement composed of clay mixed with fresh cow-dung. In the middle of the cavity is placed a pedestal composed of the same materials, for the pipes to lean against. When the pipes are sufficiently dried, they are arranged round this pedestal, resting against it and against each other, with their boles next the bottom of the furnace. They are thus placed in successive layers, till the furnace be sufficiently full, when the open space at top is filled up with bricks placed over each other, so as to leave interstices for the free circulation of the air, and of the smoke and flame which issue through the flues. In these interstices are laid several pieces of broken dried pipes, to serve as pyrometers for ascertaining the state of the included pipes during the burning. The fire is now lighted, and kept up, till, on examining the pieces of clay laid in the interstices of the bricks, it is concluded that the pipes within the furnace are sufficiently baked. The fire is then suffered to go out, and the whole to cool till the next day, when the bricks are taken down, the pipes removed, and packed in barrels for sale. After being burnt, the pipes are sometimes glazed, which is done by rubbing them, while warm, with flannel and a little white flax. In some places the extremities of the shanks are rendered smooth by dipping them before burning in the ordinary potters' glazing, which prevents that adhesion to the lips so unpleasant in new unglazed pipes.

Tobago.

TOBAGO, the most southerly of the Carribbee Islands, lies in 60° 30′ west longitude, and 11° 16′ north latitude. It is about twenty-two miles long, and from four to nine miles broad. This island was discovered by Columbus in 1496, and received its name from the herb which was smoked by the inhabitants. Sir Robert Dudley visited it in 1580; and in 1608 James I. claimed its sovereignty, though no effectual attempts were then made to colonize it. In 1628 Charles I. made a grant of the isle to the earl of Pembroke; but it continued almost deserted till 1632, when some merchants of Zealand sent over 200 emigrants, and founded a colony, to which they gave the name of New Walcheren; but before they were able thoroughly to establish themselves, they were attacked by the Spaniards of Trinidad, aided by the Indians, and the colony was utterly destroyed. Tobago remained deserted till 1654, when two opulent merchants of Flushing, named Lampsin, again colonized it, and raised it to be one of the most thriving commercial emporiums in the West Indies. About the same time the duke of Courland, to whom James I. had given a grant of the island, carried about a hundred families from Courland, and settled them on one of the most beautiful parts of the island, which was named after the founder. The island experienced various vicissitudes till it was taken by the British in 1793, in whose possession it has continued ever since.

Tobago consists of a mass of rocks, the highest part of which is towards the north-eastern extremity, where it rises to about 900 feet; it gradually descends towards the south-west, with small and delightful valleys interspersed. It is well cultivated where the rocks are not too steep. It has several good harbours, chiefly on the northern coast. The climate is considered unhealthy, the average mortality of the white troops having been ascertained to be at the rate of fifteen per cent. annually. The principal town is Scarborough, which is situated at the sea-shore, on the south coast.

By the census of 1835, the population consisted of,—

	Males.	Females.	Total.
Whites	250	30	280
Free coloured and blacks	...	...	3,000
Apprenticed labourers	4,515	5,290	9,805
			13,085

The exports of Tobago amounted in 1836 to L.196,974, of which L.166,333 were for sugar and molasses, and L.29,960 for rum; thus showing that the sugar-cane produces almost the sole exportable commodities of the island. The imports during the same period amounted to L.73,947, consisting chiefly of wood and lumber, fish, corn, and British manufactures.

In 1836 there were four free schools in the island, with 347 scholars; and four private schools, one of which is connected with the Moravians, and two with the Methodists. The local legislature consists of the lieutenant-governor, a legislative council of nine, and a house of assembly of sixteen members.

TOBERMORY. See Mull.

TOBOL, a considerable river of Asiatic Russia, which has its rise near the northern extremity of the Oural Mountains. It joins the Irtysch near Tobolsk, after a course of nearly 400 miles. Its shores are generally flat, and liable to inundation. Its upper course is traversed by wandering bands of Tartars, but in its lower course the country is more cultivated.

TOBOLSK, the name of one of the two great governments into which Asiatic Russia is divided, being the western division of that immense territory. Irkoutsk is the eastern division. Tobolsk is bounded on the west by the Oural chain of mountains, which separates it from European Russia; on the north by the Northern Ocean, the coast, broken by many deep bays, extending from the mouth of the Obi to that of the Olenek. It is separated from Chinese and Independent Tartary by an extensive frontier, partly of mountains and partly of desert plains; and from the contiguous territory of the Irkoutsk by no very definite boundary. Within the bounds of this government are included three extensive districts, which are watered by the great rivers, the Obi, the Irtysch, and the Yenisei, which include the most cultivated parts of Siberia. But the country, on the whole, is far from productive. From the northern shore of the Frozen Ocean, as far as latitude 58° north, it presents one uniform aspect of the most dismal sterility, with only a few pines and stunted shrubs, or bare moss; and a great portion of the southern parts consists of steppes or plains, covered with saline lakes or marshes. Some of these however, as the steppe of Barabinski towards the east, are covered with the most luxuriant pasturage, and would be susceptible of high cultivation, if the inhabitants had skill and industry. The agricultural districts are those on the west, on the Tobol and its tributaries, which in the lower part of their course yield most luxuriant crops; also in the east, the middle parts of the Yenisei and Obi. The rivers in those parts of Siberia abound in fish, which, notwithstanding the indolence of the inhabitants, has become a considerable article of traffic. The mountains on its western and southern frontier abound in mineral wealth. The wastes and forests are filled with innumerable wild animals, many of which are rendered valuable by their furs. But the country still labours under natural disadvantages, which render its communications difficult, and the transmission of its surplus produce to the proper market expensive. Its northern shores are inaccessible to traffic; and its vast rivers, taking their course to that ocean, lead only to the seats of poverty and barbarism. By the census of 1801, its inhabitants amounted to 622,422. These are composed of Mongols, Ostiaks, Tschuwashes, Bucharians, Tungouses, Yakoutes, Samoiedes, besides 20,000 Cossacs, and several other tribes of wandering Tartars.

Tobolsk, the capital of the above government, and of all Asiatic Russia, is a large city, and is situated at the confluence of the river Irtysch with the Tobol. It was originally, in 1587, a wooden fort, which was burned to the ground in 1643, and in its stead was erected the present city, which is composed of two parts, the high and the low town; the former built on an elevated ridge running parallel to the Irtysch at a little distance, while the latter fills the level space between it and the river. The high town contains the residence of the governor, the tribunals, public offices, and the magazine of foreign merchandise. These, along with two churches and a convent, are built of stone; the remainder are of wood. The elevated situation of the town, the whiteness of the buildings, and the gilded cupolas, give it a fine appearance from a distance. There was formerly the Kremlin, built of stone, and flanked with towers, now gone to ruin; while to the south of it is the great market-square, enclosed by stone buildings, forming two stories of merchants' shops. This part of the town, from its elevation, is secured from the risk of inundations; but seldom a year passes without the low town being overflowed. This may be considered a sort of suburb, and is built entirely of wood; and it is connected with another large suburb, formerly inhabited by Tartars, who have been removed to another and a separate quarter. The crowded manner in which they built their houses renders them extremely liable to fire. These Tartars consist of the original inhabitants, mixed with some Bucharians. The other residents are descended from exiles sent thither by the Russian government. The largest colony ever transported thither consisted of Swedish prisoners taken at the battle of Pultawa, who, being much better informed and more polished than the European Russians, greatly improved the Siberian society of Tobolsk, by opening seminaries of education, in which were taught ancient and modern languages, geography, mathematics, and drawing. Provisions are extremely cheap in this city; and the neighbouring woods and rivers afford the finest hunting and fishing in the world. Society and manners are also greatly improved, so as, according to Dr Clarke, to equal these in any other Russian city. Tobolsk is the commercial emporium of Siberia, in which centres all the trade that is carried on in this quarter. The most important branch of it is that which traverses an immense ntent of land and river carriage between European Rus- a and China. The merchants from Europe arrive in ring, and return with the produce of the east at the end summer to Moscow and St Petersburg; and those from artary and Bucharia arrive in the beginning of winter, hich they spend at Tobolsk, and return in spring. All e furs collected as tribute from the tribes who wander er the immense desert of Siberia are brought to Tobolsk, which are large magazines for depositing these various ods. Population 16,269. Long. 68. 15. E. Lat. 58. 2. N. (F.)

TOBOSA, a town, or rather a large village, of Spain, in e province of La Mancha and the partido de Infantes. stands on the great road from the province to Madrid, d contains about 2200 inhabitants; and is only remark- le from being the supposed residence of the imaginary ulcinea of Don Quixote.

TOCAT, or Tokat, a large and commercial city of Asia inor, in the pachalic of Sivas. It is built in the form of amphitheatre, and is situated in a deep valley on the nks of the Jekil Irmak, the ancient Iris. The streets, ough steep, from the unevenness of the ground, are well ved. Several manufactures are carried on in the place, mely, of vessels of copper, kettles, candlesticks, with which supplies the neighbouring provinces; also of blue morocco d silk stuffs. It is a commercial mart of some note to and om all parts of Asia Minor. The population, amounting, cording to Kinneir, to 60,000, consists chiefly of Turks, considerable number of Armenians, who have seven urches, and a few Greeks, who have only one church. he trade is carried on by means of caravans, which arrive eighteen days from Diarbekir, in six from Sinope, in enty from Boursa, and in twenty-seven from Smyrna. To- t is the ancient Berisa. Forty miles north-west of Sivas. ong. 36. 30. E. Lat. 39. 35. N.

TOCCATA (*Ital.*), an old-fashioned piece of music of nsiderable difficulty, generally written for the harpsichord the organ, but sometimes for the violin. Clementi's mo- ern *toccata* for the pianoforte is an admirable study for at instrument.

TOCKENBURG, a long and narrow valley of the nton of St Gall, in Switzerland. The length of this val- y is thirty-six miles; and through the whole of it the river hur rushes with impetuous force, from its source on the estern side of the Sentis, to its entrance into the Rhine at lken, in the canton of Zürich. A range of lofty and pie- resque mountains, forming a rampart round this valley, parates it from the Rhinthal and the lake of Wallenstadt. he valley contains 50,000 inhabitants, who adhere to the formed religion. The weaving of linen forms one part their occupation. The chief place is the small town of ichtenseig.

TODDINGTON, a town of the county of Bedford, in e hundred of Mamshead, thirty-seven miles from London d four from Dunstable. It had formerly a market, but has gradually declined, and at length disappeared; but e town still has four well-attended annual fairs. The popu- tion amounted in 1801 to 1143, in 1811 to 1182, in 1821 1665, and in 1831 to 1926.

TOGA, in Roman antiquity, a wide woollen gown or antle, which seems to have been of a semicircular form, ithout sleeves; differing both in richness and largeness, cording to the circumstances of the wearer, and used ly upon occasion of appearing in public. Every body nows that the toga was the distinguishing mark of a Ro- an. Hence the *jus togæ*, or privilege of a Roman citizen, e. the right of wearing a Roman habit, and of taking, as ey explain it, fire and water through the Roman empire.

TOKA, a town of some consequence, in Hindustan, pro- ince of Aurungabad. Long. 75. 10. E. Lat. 19. 25. N.

TOKAY, or Tokai, a town of the Austrian kingdom of Hungary, in the division of Semplin. It is situated on the river Theiss, at the point where the waters of the Bodrog fall into that stream. It was once considered an important military post; and was then the great store-cellar of the wine of Prince Bagotzky. Tokay contains 3200 inhabitants, of the Lutheran, Calvinistic, and Catholic confessions, each of which has its church. From this town the celebrated wine produced in the vicinity has received its name in most parts of Europe, though at home, ever since 1741, it is more commonly denominated Theresienberg, from the name of a hilly district. The best is produced on the hills of Mada, Tarckzal, and Zomba, which are connected with the Carpathian range of mountains. The whole quantity of this wine which is yearly produced does not on an average amount to more than 110,000 eimers, a measure equal to twenty English gallons.

TOKEN Besseys, a cluster of very small isles situated off the east coast of the island of Booton. Long. 123. 35. E. Lat. 5. 40. S. These islands are all connected by narrow straits, between which run very rapid currents, that render the navigation dangerous.

TOLAND, John, a well-known writer, was born near Londonderry, in Ireland, in 1670, and educated in the Popish religion, but at sixteen years of age embraced the principles of the Protestants. He studied three years in the university of Glasgow; took the degree of A. M. in that of Edinburgh; and afterwards completed his studies at Leyden, where he resided two years. He then went to Oxford, where, having the advantage of the public library, he collected materials upon various subjects, and composed some pieces; among which was, a dissertation to prove the received history of the tragical death of Atilius Regulus, the Roman consul, to be a fable. He began likewise a work of greater consequence, in which he undertook to show that there are no mysteries in the Christian religion. He published it in 1696, at London, under the title of Christianity not Mysterious. This book gave great offence, and was attacked by several writers. He afterwards wrote in favour of the Hanoverian succession, and many other pieces. In 1707 he went into Germany, where he visited several courts; and in 1710 he was introduced to Prince Eugene, who bestowed upon him several marks of his generosity. Upon his return to England, he was for some time supported by the liberality of the earl of Oxford, lord-treasurer, and kept a country house at Epsom; but soon losing his lordship's favour, he published several pamphlets against that minister's measures. During the last four years of his life he lived at Putney, but used to spend most part of the winter in the metropolis. He died at London in 1722. He was a man of uncommon abilities, published a number of curious tracts, and was perhaps the most learned of all the infidel writers; but his private character was far from being an amiable one, for he was extremely vain, and wanted those social virtues which are the chief ornaments as well as duties of life. Four years after his death, appeared "A Collection of several Pieces of Mr John Toland, now first published from his original manuscripts: with some memoirs of his life and writings." Lond. 1726, 2 vols. 8vo. The memoirs were written by Des Maizeaux. The first volume includes a History of the Druids, extending to 228 pages.

TOLEDO, a province of Spain, forming a part of the ancient kingdom of Old Castille. It extends in north latitude from 39° 3′ to 40° 54′, and in west longitude from 3° 1′ to 5° 32′, and comprises 734 Spanish square leagues, or about 9060 English square miles. It is bounded on the north by the provinces of Madrid and Guadalaxara, on the east by Cuença, on the south by La Mancha, on the south-west by Estremadura, and on the north-west by Avila and Salamanca. The land is lofty and mountainous, with wide and uniform plains, almost destitute of trees. The soil is mostly calcareous and sandy, and on the hills stony, but highly productive in situations in which it can be duly watered. The mountains of this province form a distinct chain, which shoots from Cuença, commences with small hills in the vicinity of Tarascon and Tembleque, then turns to the south, and by Madrilejos gradually attains the height of 2500 feet. It next turns to the west, and forms the Sierra of Yevernes; and then, under the name of Guadalupe, enters the province of Estremadura. The several spurs from this chain are called by various names.

The chief river of the province is the Tagus, which receives a great number of tributary streams within it, and others in Estremadura, through which province it passes in its course to Lisbon, where it terminates. It is not navigable in Toledo, though, with little expense, it might be easily made so. The river Guadiana enters the province in the south-east part, and is soon lost in the sands, and does not re-appear till it enters La Mancha. It then continues its course as a considerable stream by Badajos, having its water increased by various tributary rivers and rivulets, till it enters the sea at Ayamonte, on the south-east frontier of Portugal. Notwithstanding these rivers, the want of water is a subject of complaint, as there are few or no wells. According to the latest, not very satisfactory, statement by Canga Arguelles, the population in 1797 was 370,641 persons, composing 74,128 families, occupying 68,953 dwellings, but leaving 4979 ruined or unoccupied houses. The description of the people, as given by the same author, is as follows: Nobles, 1430; labouring proprietors, 11,215; labouring tenants, 7155; day-labourers, 37,075; artisans, 10,127; traders and merchants, 797; public officers, 682; domestic servants, 6969; secular ecclesiastics, 2929; regular ecclesiastics, or monks and friars, 2969; and females in convents, 1569.

Toledo, a city of Spain, the capital of a province, and of a subdivision or partido, of the same name. It is remarkable in history from having been the capital of the Moorish kings during their government of the peninsula; and it was distinguished at the commencement of the reign of Charles V. as the scene of the insurrection, in 1522, of Don Juan de Padilla, who was here executed after his defeat. It stands on the river Tagus, on some hills rising from it; and the city is thus rendered uneven and very irregular. There are two old strong bridges over the river. Toledo is surrounded by ancient walls, protected by towers, but is not defensible against modern modes of attack. The interior of the city has narrow streets, and many large buildings of very antique architecture. The most remarkable is the cathedral, an enormous pile in the Gothic style, ornamented with a vast quantity of decorations. It is 410 feet in length, 210 in breadth, and 112 feet in height. The other remarkable churches are those of St Thomas, of the Dominicans, and the Carmelites. The ancient palace of the Moorish kings is a very striking object, now converted into an hospital. The city suffers much from the want of water, the only supply being from the river, and conveyed to the houses on the backs of asses. Toledo is the seat of a university. The archbishopric is the richest in Spain, and the dignity is commonly filled by a member of the royal family. The archbishop has eight suffragan bishops under him, and enormous revenues, which are distributed largely in provisions, and this circumstance causes the city to swarm with idle beggars. This place was celebrated for the excellence of its sword blades; a manufacture introduced by the Moors, but now nearly, if not wholly, extinct. The silk and soap trades give some occupation. The number of inhabitants at present is supposed to be about 25,000, but is uncertain. Toledo was the birth-place of the dramatic poet Garcilaso de la Vega, and of the great critic Tostado. Long. 3. 27. 57. W. Lat. 40. 28. 40. N.

TOLERATION, in matters of religion, is either civil or ecclesiastical. Civil toleration is an impunity and safety granted by the state to every sect that does not maintain doctrines inconsistent with the public peace; and ecclesiastical toleration is the allowance which the church grants to its members to differ in certain opinions not reputed fundamental.

As the gods of paganism were almost all local and tutelary, and as it was a maxim universally received that it was the duty of every man to worship, together with his own deities, the tutelary gods of the country in which he might chance to reside, there was no room for persecution in the heathen world, on account of different sentiments in religion, or of the different rites with which the various deities were worshipped. Had the primitive Christians joined their fellow-citizens in the worship of Jupiter, Juno, and the rest of the rabble of Roman divinities, they would have been suffered to worship, without molestation, the Creator of the world and the Redeemer of mankind; for in that case the God of the Christians would have been looked upon as a being of the same kind with the gods of the empire, and the great principle of intercommunity would have remained unviolated. But the true God had expressly prohibited both Jews and Christians from worshipping any other god besides Himself; and it was their refusal to break that precept of their religion which made their heathen masters look upon them as atheists, and persecute them as a people inimical to the state. Utility, and not truth, was the object for which the heathen legislatures supported the national religion. They well knew that the stories told by their poets, of their different divinities, of the rewards of Elysium, and of the punishments of Tartarus, were a collection of senseless fables; but they had nothing better to propose to the vulgar, and they were not such strangers to the human heart as to suppose that mankind could live together in society without being influenced in their conduct by some religion.

Widely different from the genius of paganism was the spirit of the Jewish dispensation. Truth, which is in fact always coincident with great utility, was the great object of the Mosaic law. The children of Israel were separated from the rest of the world, to preserve the knowledge and worship of the true God, at a time when all the other nations on earth, forgetting the Lord that made them, were falling prostrate to stocks and stones, and worshipping devils and impure spirits. Such was the contagion of idolatry, and so strong the propensity of the Israelites to the customs and manners of the Egyptians, and other polytheistic nations around them, that the purpose of their separation could not have been served, had not Jehovah condescended to become not only their tutelary God, but even their supreme civil magistrate; so that under the Mosaic economy, idolatry was the crime of high treason, and as such justly punished by the laws of the state. Among the Jews, the church and state were not indeed different societies. They were so thoroughly incorporated, that what was a sin in the one was a crime in the other; and the forfeiture of ecclesiastical privileges was the forfeiture of the rights of citizens.

In many respects the Christian religion is directly opposite to the ritual law of Moses. It is calculated for all, and intended to be propagated among all nations. Instead of separating one people from another, one of its principal objects is to disseminate universal benevolence, and to inculcate upon the whole human race that mutual love which naturally springs from the knowledge that all men are brethren. Its ultimate end being to train its votaries for heaven, it concerns itself no further with the affairs of earth than to enforce by eternal sanctions the laws of morality; and the kingdom of its Founder not being of this world, it leaves every nation at liberty to fabricate its own municipal laws, so as best to serve its own interest in the various circumstances in which it may be placed; and denounces a

Tollo

Isle.

curse upon all who pay not to those laws the fullest obedience, when they are not obviously inconsistent with the laws of piety and virtue, which are of prior obligation. The Christian church therefore must always remain a society distinct from the state; and though, till the present age of hazardous innovations, it has been deemed expedient in every country where the truth of the gospel is admitted, to give to the religion of Christ a legal establishment, and to confer immunities on its ministers, this measure has been adopted, not to secure the purity of the faith, which appeals to the private judgment of each individual, but merely to preserve the peace of society, and to impose a restraint upon those actions of which human laws cannot take cognizance. With religion, Christian governments have no further concern than as it tends to promote the practice of virtue. The early Christians, however, not understanding the principle upon which penal laws were employed to preserve the purity of the Jewish religion, and, as our blessed Lord observed to two of his apostles, not knowing what spirit they were of, hastily concluded that they had a right to enforce the doctrines and worship of the New Testament, by the same means which had been used to preserve the Israelites steady to the doctrines and worship of the Old. Hence, though they had themselves suffered the most cruel persecutions, they no sooner had the power of the state in their hands, than they persecuted the pagans for their idolatry; and afterwards, when heresies arose in the church, persecuted one another for expressing in different phrases metaphysical propositions, of such a nature as no human mind can fully comprehend. The apostle had forewarned them that there must be heresies in the church, that they who are approved may be made manifest; but it did not occur to them that persecution for opinion is the worst of all heresies, as it violates at once truth and charity.

Hitherto these unhallowed means of bringing Christians to uniformity of faith and practice, had been only occasionally employed, from their not accurately distinguishing between the spirit of the gospel and that of the law; but as soon as the bishops of Rome had brought the inhabitants of Europe to recognise their infallibility in explaining articles of faith and deciding points of controversy, persecution became a regular and permanent instrument of ecclesiastical discipline. To doubt or to deny any doctrine to which these unerring instructors had given the sanction of their approbation, was held to be not only a resisting of the truth, but an act of rebellion against their sacred authority; and the secular power, of which, by various arts, they had acquired the absolute direction, was instantly employed to avenge both.

Thus Europe had been accustomed, during many centuries, to see speculative opinions propagated or defended by force; the charity and mutual forbearance which Christianity recommends with so much warmth were forgotten; the sacred rights of conscience and of private judgment were unheard of; and not only the idea of toleration, but even the word itself, in the sense now affixed to it, was unknown. A right to extirpate error by force was universally allowed to be the prerogative of those who possessed the knowledge of truth; and though the first reformers did not arrogate to themselves in direct terms that infallibility which they had refused to the church of Rome, they were not less confident of the truth of their own doctrines, and required with equal ardour the princes of their party to check such as presumed to impugn or to oppose them. To this request too many of these princes lent a willing ear. It flattered at once their piety and their pride, to be considered as possessing all the rights of Jewish princes; and Henry the Eighth of England, after labouring to make his divines declare that all authority, ecclesiastical as well as civil, flows from the crown, persecuted alternately the Papists and Protestants. Many of his successors, whose characters were much better than his, thought themselves duly authorized, by virtue of their acknowledged supremacy over all states and conditions of men, to enforce by means of penal laws a uniformity of faith and worship among their subjects; and it was not till the revolution that any sect in England seems to have fully understood, that all men have an unalienable right to worship God in the manner which to them may seem most suitable to his nature, and the relation in which they stand to him; or that it is impossible to produce uniformity of opinion by any other means than candid disquisition and sound reasoning. That the civil magistrate has a right to check the propagation of opinions which tend only to sap the foundations of virtue, and to disturb the peace of society, cannot, we think, be questioned; but that he has no right to restrain mankind from publicly professing any system of faith which comprehends the being and providence of God, the great laws of morality, and a future state of rewards and punishments, is as evident as that it is the object of religion to fit mankind for heaven, and the whole duty of the magistrates to maintain peace, liberty, and property, upon earth. We have elsewhere observed, that among a number of different sects of Christians, it is not the superior purity of the system of faith professed by one of them, that gives it a right to the immunities of an establishment in preference to all its rivals; but though the legislature is authorized, in certain circumstances, to make a less pure system the religion of the state, it would be the height of absurdity to suppose that any man, or body of men, can have authority to prevent a purer system from being acknowledged as the religion of individuals. For propagating opinions and pursuing practices which necessarily create civil disturbance, every man is answerable to the laws of his country; but for the soundness of his faith, and the purity of his worship, he is answerable to no tribunal but that which can search the heart.

When churches are established, and creeds drawn up as guides to the preaching of the national clergy, it is obvious that every clergyman who teaches any thing directly contrary to the doctrine of such creeds, violates the condition on which he holds his benefice, and may be justly deprived of that benefice, whether his obnoxious opinion be in itself true or false, important or unimportant; but his punishment should be extended no farther. To expel a Christian from private communion for teaching any doctrine which is neither injurious to the state nor contrary to the few simple articles which comprise the sum of the Christian faith, is the grossest tyranny; and the governors of that church which is guilty of it usurp the prerogative of the blessed Lord, who commanded the apostles themselves not to be called masters in this sense; for one, says he, is your master, even Christ. It is indeed a hardship to deprive a man of his living for conscientiously illustrating what he believes to be a truth of the gospel, only because his illustration may be different from that which had formerly been given by men fallible like himself; but if the establishment of human compilations of faith be necessary, this hardship cannot be removed but by making such compilations as simple as possible, and drawing them up in scripture language. Such a reformation, could it be effected peaceably, would serve other good purposes; for while it would sufficiently guard the purity of the faith, it would withdraw that temptation which too many establishments throw in the way of men to subscribe to the truth of what they do not really believe; and it would effectually banish from the Christian church every thing which can be called by the name of *persecution*.

TOLLO, or Tolour Bay, a great bay on the east coast of the island of Celebes, very broad at the entrance.

TOLOUR Isle, the largest of the Salibabo Isles, named Kercolang by Captain Hunter. It is a well-cultivated and populous island. The inhabitants are chiefly Mahommedans, who exhibit a considerable degree of cultivation. It is fertile, every part being covered with trees and verdure. It is about eighty or a hundred miles in circumference, and lies between the 4th and 5th degrees of north lat. and about 126. 30. east long.

TOLSTONOSKOI, a fort of Asiatic Russia, in the government of Tobolsk, on the Yenisei, 280 miles north-north-west of Turuchansk.

TOMB includes both the grave or sepulchre in which a person is interred, and the monument erected to preserve his memory. The word is formed from the Greek τύμϐος, *tumulus*, sepulchre; or, according to Menage, from the Latin *tumba*, which has the same signification.

In many nations it has been customary to burn the bodies of the dead, and to collect the ashes with pious care into an urn, which was deposited in a tomb or sepulchre. Among many other nations it has been the practice to lay the dead body in a tomb, without consuming it, after having wrapped it up decently, and sometimes placing it in a coffin. The tombs of the Jews were generally hollow places hewn out of a rock. Abraham buried Sarah in a cave. Such was also the place in which the kings of Judah and Israel were interred; and such was the place in which the body of our Saviour was deposited by Joseph of Arimathea. But it is probable that the common people buried their dead in graves; for our Saviour compares the Pharisees to "graves which appear not, and the men that walk over them are not aware of them." Over the tombs, perhaps only of people of distinction, a stone or monument was erected, to intimate to passengers that they were burying-places, that they might not pollute themselves by touching them. With the same intention, as Dr Lightfoot informs us, they whitened them every year on the 15th of February. The Egyptians buried their dead in caves, called *catacombs*. The pyramids, as some think, were also employed for the same purpose. Sometimes, after embalming their dead, they placed them in niches in some magnificent apartment in their houses.

The Greeks and Romans burned their dead, and deposited their ashes in a tomb. The Greeks interred the ashes without the cities, by the sides of their highways. Sometimes, indeed, by way of particular honour, they were buried in an elevated part of the town; and the Lacedæmonians were allowed by Lycurgus to bury in the city and round their temples. But this was forbidden among the Romans by the law of the twelve tables: *In urbe ne sepelito, neve urito.* Valerius Publicola, Posthumus Tubertius, and the family of the Claudii, were however buried in the Capitol. To bury by the sides of public roads was also common among the Romans; and hence their epitaphs frequently began with *Siste viator.* Highways were probably selected for two reasons; that the dead might not be offensive or injure the health of the living; and that they might supply a lesson of mortality.

As it would swell this article to too great a size to describe all the different kinds of tombs which have been used by different nations and ages, we must content ourselves with shortly describing the tombs of a few nations, and adding a few concomitant circumstances.

The tombs of the Parsees are singular. After lying a proper time in his own house for the purposes of mourning, the deceased, followed by his relations and friends, the females chanting a requiem, is deposited in a tomb of the following construction. It is a circular building, open at top, about fifty-five feet in diameter and twenty-five feet in height, filled to within five feet of the top, excepting a well of fifteen feet diameter in the centre. The part so filled is terraced, with a slight declivity toward the well. Two circular grooves, three inches deep, are raised round the well; the first at the distance of four, the second at ten, feet from the well. Grooves of the like depth or height, and four feet distance from each other, at the outer part of the outer circle, are carried straight from the wall to the well, communicating with the circular ones, for the purpose of carrying off the water, &c. The tomb, by this means, is divided into three circles of partitions; the outer, about seven feet by four; the middle, six by three; the inner, four by two; the outer for the men, the middle for the women, the inner for the children; in which the bodies are respectively placed, wrapped loosely in a piece of cloth, and left to be devoured by the vultures; which is very soon done, as numbers of those animals are always seen hovering and watching about these charnel-houses, in expectation of their prey. The friends of the deceased, or the persons who have charge of the tomb, come at the proper time, and throw the bones into their receptacle, the well in the centre; for which purpose iron rakes and tongs are deposited in the tomb. The entrance is closed by an iron door, four feet square, on the eastern side, as high up as the terrace, to which a road is raised. Upon the wall, above the door, an additional wall is raised, to prevent people from looking into the tomb, which the Parsees are particularly careful to prevent. A Persian inscription is engraved on a stone over the door. From the bottom of the wall, subterraneous passages lead to receive the bones, and prevent the well from filling.[1]

Of the ancient sepulchres found in Russia and Siberia, some are perfect tumuli, raised to an enormous height, while others are almost level with the ground. Some of them are encompassed with a square wall of large quarry-stones placed in an erect position; others are covered only with a small heap of stones, or they are tumuli adorned with stones at top. Some are walled with brick within, and vaulted over; others are no more than pits or common graves. In some the earth is excavated several fathoms deep; others, and especially those which are topped by a lofty tumulus, are only dug of a sufficient depth for covering the carcass. In many of these sepulchres, the bones of men, and frequently of horses, are found, and in a condition that renders it probable the bodies were not burnt before they were inhumed. Other bones show clearly that they have been previously burnt; because a part of them is unconsumed, and because they lie in a disordered manner, and some of them are wanting. Urns, in which other nations of antiquity have deposited the ashes of their dead, are never met with here; but sometimes what remained of the bodies after combustion, and even whole carcasses, are found wrapped up in thin plates of gold. Many dead bodies are frequently seen deposited together in one tomb; a certain indication that either a battle had been fought in the neighbourhood of the place, or that some families buried their relations in an hereditary tomb.

The Moors, like all other Mahommedans, hold it contrary to the spirit of religion to bury their dead in mosques, and to profane the temple of the Most High by the putrefaction of dead bodies. In the infancy of the church, the Christians had the like respect for their temples. The burial grounds of the Mahommedans are without the city; the emperors have their sepulchres distinct and distant from the mosque, in sanctuaries built by themselves; and their tombs are exceedingly simple. All Mahommedans inter the dead at the hour set apart for prayer. The defunct is not kept in the house, except he expires after sunset; but the body is transported to the mosque, whither it is carried by those who are going to prayer. Each, from a spirit of devotion, is desirous to carry in his turn. The Moors sing at their burial service; which usage they have perhaps imitated after the Christians of Spain. They have no particular colour appropriated to mourning. Women regularly go on the riday to weep over and pray at the sepulchres of the dead, hose memory they hold dear.

TOMBUCTOO. See Timbuctoo.

TOMINIE Bay, a bay which deeply indents the north-ast quarter of the island of Celebes, and abounds with mall rocky islets and rocky shoals. It is often called Go-ong Tellu Bay.

TOMOGUY, a small island in the Eastern Seas, about wo miles round. Long. 127. 4. E. Lat. 0. 15. S.

TOMPION, a sort of bung or cork used to stop the iouth of a cannon. At sea this is carefully encircled with illow or putty, to prevent the penetration of the water into ie bore, whereby the powder contained in the chamber iight be damaged or rendered incapable of service.

TOMSK, a large city, capital of an extensive district in siatic Russia. It is situated on the Tom, about twenty-ve miles from its junction with the Obi. Like most of the iberian cities, it was originally a small wooden fort; but eing consumed by fire, it was rebuilt on a larger scale in 648. It is built on remarkably irregular and broken round; especially the old part of the town, where the reets are narrow and winding, and the houses out of all ne or order. But the town being built mostly of wood, nd liable to frequent fires, an opportunity was given of reeting houses and streets on a regular plan. Within the ircuit of the Kremlin, a fortress constructed in the seven-eenth century, and now almost entirely in ruins, are the athedral church, the tribunals, the treasury, with the ma-azine of furs collected as tribute. In the other part of ie city is the church of the resurrection, the principal edi-ce; and there are two convents, the one of monks, the ther of nuns. The place is very advantageously situated or commerce, by which the inhabitants chiefly subsist, be-ig on the great line of rivers which connects Tobolsk with he Chinese frontier and the eastern parts of Siberia. It s also the centre of the trade in spirits, which are brought hither from the distilleries on the Tobol and the Iset, and hence distributed to the countries eastward. The inhabi-ants are not so civilized as those of Tobolsk and Irkoutsk, nd they are much addicted to intoxication. Pallas men-ions that, prevalent as this vice is in Siberia, he never saw ny town where it was so common as at Tomsk. The po-ulation, amounting to upwards of 11,000, consist, besides Russians, of a great number of Tartar, Bucharian, and Kal-nuck merchants. Tomsk has been erected into the capi-al of a government, which comprehends a great part of the ountries situated on the Obi, and most of those on the Ye-isei. Long. 84. 10. E. Lat. 56. 30. N.

TONALITY, in *Music* (Ital. *tonalità*, Fr. *tonalité*), a odern term, introduced to designate the existence of dif-erences among various musical modes, ancient and mo-lern, and among the elements of melodies and harmonies ounded upon these modes. See Music, pp. 611, 612, nd pp. 61–68 of Appendix to Graham's Essay on Musical Composition. Peculiarities of tonality among different na-ions may be accounted for by particularities in the con-truction of musical instruments (see Music and Trumpet), or by particularities in intonation adopted by vocal per-ormers, and consecrated by that mighty power, custom, which rules and moulds so many of human feelings, opinions, and actions. G. A. Villoteau, a professional musician, ap-ointed by Napoleon to collect musical information in the expedition to Egypt, states that our modern scale of C ma-or was a complete stumbling-block to the oriental musi-cians. He says, "J'ai eu l'occasion de m'en convaincre moi-même en Egypte, en essayant de la faire chanter à des musiciens Grecs, Egyptiens ou Arabes, Ethiopiens, Persans, Arméniens et Syriens; et vraiment les grimaces et les contortions qu'étoient obligés de faire ces bonnes gens pour atteindre avec la voix jusqu'à notre Si naturel (B natural), qu'ils s'efforçoient cependant, et de la meilleure foi du monde, d'entonner, mais toujours sans succès, me paroissoient si singulièrement risibles, que je crois qu'il m'auroit été impossible de les regarder de sang-froid, si le motif qui me déterminoit à faire cette expérience n'eût occupé alors toute mon attention." See also his paper on the state of music in Egypt, in the great French work, *Description de l'Egypte*, where he gives a curious account of his studies under an Arabian musician at Cairo, and the great disagreement between the European and oriental tonalities. In the same work he gives some remarkable specimens of oriental music. The establishment of one major and one minor scale in Europe may be dated about two centuries ago. Before that time, the system of tonality was founded upon the church tones or modes; and the harmony employed consisted of common chords with an occasional chord of $^{6}_{5}$. About the end of the sixteenth and beginning of the seventeenth centuries, Claudio Monteverde, a musician of the Venetian school, began to employ a system of harmony different from the old. He used the minor 5th, the major 4th, the minor 7th, the 9th, and also even double dissonances, unprepared; but his application of the chord of $^{7}_{5}$ to the dominant of the key, was the most important of his innovations, as it led to the abandonment of the old ecclesiastical tonalities and harmonies, and the rapid establishment of the modern European tonality and harmony. From Monteverde's discoveries arose diminished and augmented intervals and chords, what is called chromatic music, and melodic and harmonic modulation. The majority of modern musicians who have attempted to harmonize ancient European melodies, seem to have been ignorant of the marked distinctions between ancient and modern tonalities in Europe, and of the fact that most of these airs are constructed upon tonalities to which modern harmony, which depends upon a newer system of tonality, cannot be continuously applied. See the Essay on Composition above cited, pp. 68, 69 of Appendix. (G. F. G.)

TONDI, a seaport town in the south of India, province of the Carnatic, district of Marawas. Long. 76. 5. E. Lat. 9. 43. N.

TONE, in *Music*. See Music.

TONG, a city of China, of the second rank, in Pe-che-lee, on the river Peiho, ten miles east of Pekin. Long. 116. 20. E. Lat. 40. 56. N.

TONGA Islands. See Friendly Islands.

TONGATABOO Island, one of the Friendly Islands, in the South Pacific Ocean, about sixty miles in circuit. It was first discovered by Tasman. Long. of the middle of the island 175. W. Lat. 21. 11. S.

TONG-GIN, a city of China, of the first rank, on the borders of Houquang, in the environs of which are mines of gold and silver. 850 miles south-south-west of Pekin. Long. 108. 37. E. Lat. 27. 39. N.

TONGHO, a celebrated fortress and capital of a district of the same name in the Birman empire. The district is situated about the nineteenth degree of north latitude, and the ninety-eighth degree of east longitude. It is fertile and extensive, and constitutes the principality of one of the king's sons. The town is built of wood, and is surrounded by a deep ditch and a stockade. Long. 96. 49. E. Lat. 18. 50. N.

TONG-TCHANG, a city of China, of the first rank, on the grand canal. It carries on an extensive trade in grain and fruits. It is 212 miles south of Pekin. Long. 115. 40. E. Lat. 36. 34. N.

TONG-TCHOUEN, a city of China, of the first rank, in Sechuen, strongly fortified, being on the Tartar frontier. Long. 103. 2. E. Lat. 26. 20. N.

TONK RAMPOORAH, a rajpoot town, in the province of Ajmeer, sixty miles south by east of Jyenagur. Long. 75. 58. E. Lat. 26. 7. N.

TONNAGE.

TONNAGE has long been an official term, intended originally to express the burthen that a ship would carry, in order that the various dues and customs which are levied upon shipping might be levied according to the size of the vessel, or rather in proportion to her capability of carrying a burthen. It has hence arisen that the term "tonnage," as applied to a ship, has become almost synonymous with that of size. It is indeed the only term that is used to give an idea of the magnitude of merchant-ships, which are invariably spoken of according to their tonnage, or as being ships of 50, of 500, or of 1000 tons. Not only are all dues and customs levied according to the tonnage, but ships are also built, and bought, and sold, for a price per ton of their admeasurement; and by the conditions of Lloyd's classification-list of shipping, they must be timbered and fastened, and must have their anchors, cables, and boats, all in proportion to the same datum. Tonnage, therefore, in so far as these considerations are involved, is virtually assumed to be a correct representation of the size of a ship.

In order to levy the dues on shipping, it was necessary to establish some one method to be in general use for calculating this tonnage; and consequently there has long been a rule, enforced by law, for the measurement of the tonnage of ships or vessels, and much mischief has arisen to the mercantile shipping of Great Britain through the erroneous principles which have been adopted at various times in forming these rules.

It is evident that tonnage may express several results of measurements, and in each case may be a sufficiently fair criterion of the burthen of a merchant-vessel, by which to levy the dues; because all that is required thus far, either on the part of the government or of private interests, or on that of the owner, is, that the dues should be levied in equal proportions on all vessels. Thus tonnage may be the product of a series of measurements, intended to express either the exact size, or an approximation to the exact size, of the ship. It may be the actual displacement or weight of the ship, either with or without cargo; it may be the displacement of the cargo, or the dead-weight which she will carry to a fixed draught of water; or it may be the capacity of the space which she has for the stowage of cargo. Yet to each of these there are most important practical objections. The first, or that by which the measured bulk of the ship would be the tonnage, might be easily evaded, and would lead to injurious results; because, as there must necessarily be fixed measuring places, such a law would have the effect of restricting the form of vessels to that one shape which would carry the largest cargo under the least possible measurements at these places. If the actual displacement, either load or light, of a vessel, were to be her tonnage, it would be subject to the inconvenience that it could only be calculated correctly from the drawing of the ship, and therefore would be inapplicable to foreign ships arriving in our ports. An exact account of the draught of water, either load or light, would also be necessary; which, as being a variable quantity when the load draught is involved, and one of great difficulty to be determined when the light draught is required, would present almost insuperable objections; and, besides, the draught of water is a quantity easily concealed or falsified for fraudulent purposes. Above all objections, however, may be reckoned this, that if either the load or the light displacement were taken to represent the tonnage, it would be the interest of the shipowner to build large vessels with slight scantling and inadequate fastening, that the weight of the vessel might be small in proportion to that of the cargo. If the tonnage were to express the difference between the two displacements, that is, the excess of the load displacement over the light, or the dead-weight of the lading, although this would be by far the most correct in principle,—in fact, although it be even mathematically correct,—there is the objection against it, that it involves a knowledge of both light and load draughts of water; and is therefore on this account, practically at least, as objectionable as the whole displacement. Lastly, if the tonnage were to be the space or capacity for the stowage of cargo, numerous openings would be afforded for fraudulent evasion; because the manner of measuring the ship for this space must be defined, and it is easy to build space which will not come within the limits of the defined measurements; or it is easy to build a vessel of such a form that the measurements made at the given measuring places shall not give a correct account of her capacity.

Until January 1836, the rule for computing the tonnage of ships was as follows. The length was taken on a straight line along the rabbet of the keel of the ship, from the back of the main stern-post to a perpendicular line from the fore part of the main stem under the bowsprit. The breadth was taken from the outside of the outside plank in the broadest part of the ship, either above or below the main wales, exclusively of all manner of doubling planks that might be wrought upon the sides of the ship. If the ship to be measured was afloat, a plumb-line was dropped over the stern, and the distance between such line and the after part of the stern-post, at the load water-mark, was measured; then was taken the length from the top of this plumb-line, in a direction parallel with the water, to a perpendicular immediately over the load water-mark, at the fore part of the main stem. Subtracting from this length the before-mentioned distance between the plumb-line and the after part of the stern-post, the remainder was reckoned to be the ship's extreme length, from which three inches were deducted for every foot of the load draught of water. With the dimensions thus obtained, the rule then was: "From the length taken in either of the ways above mentioned, subtract three fifths of the breadth taken as above; the remainder is esteemed the just length of the keel to find the tonnage; then multiply this length by the breadth, and that product by half the breadth, and dividing by 94, the quotient is deemed the true contents of the tonnage."

This rule is still in force for ships that were registered previously to the passing of the new act. It is evident that the tonnage as determined by it was intended to express the size or bulk of the ship, the half breadth being an assumed equivalent for a mean depth. The evils which arose out of this assumption were very great. As the depth was not at all involved, it might be increased to any extent without increasing the tonnage; while, on the contrary, as the square of the breadth was involved, an undue preponderance was given to this dimension, and it became necessary, on the part of ship-owners, to restrict it within the least possible limits. The effect of such a law was obvious. The British merchant-ships, in order to profit by its inconsistencies, were built exceedingly narrow and deep in proportion to the length, so that, according to parliamentary returns, we find, on an average, the mercantile navy would carry $\frac{1}{3}$d more weight than its legally registered tonnage. In fact, the ships became little more than oblong boxes, most dangerous as sea-boats, and, from their want of stability, not capable of carrying sufficient sail to insure their safety on lee shores. Hence, after every gale of wind, the leeward coasts were covered with their wrecks; and hence Lloyd's books registered annually the average loss of six ships in four days.

Out of this uncertainty of navigation arose a most heartless system of gambling in maritime-insurance, the temptations of which were as destructive to the mercantile honour and the morality of the nation, as the inefficiency of the ships was destructive to its seamen. Luckily, this cause of reproach has ceased since the enactment for calculating the tonnage of vessels, which has been in force from January 1836; and numbers of ships are now built that very forcibly prove how injuriously the old law must have operated in checking maritime and commercial adventure. Not that we mean to say the present law is by any means perfect, or that the rule for calculating the tonnage cannot be evaded, because this is not the fact; it can be and is evaded, but the evasions are not so destructive to the good qualities of ships as those which were commonly practised during the continuance of the old law. It is doubtful whether, in a nation whose existence depends upon her maritime superiority, ships should not be exempted from all dues. These pages are not the place to inquire how it might be possible to accomplish so desirable an exemption; or how compensating revenues could by any means be awarded to the harbours, the docks, or the lights, which are now maintained by a taxation levied upon the tonnage of shipping. It does not, however, appear difficult to conceive that the same revenue might be drawn from the freights which the ships carry, as the merchant would receive it back from the ship-owner in the shape of a diminished freightage.

It is exceedingly difficult, probably even impossible, to frame a rule for computing the tonnage which shall be at once of practical application, and yet not have in some degree the effect of restricting improvement in the qualities of merchant-ships. It is difficult to induce a man to forego a constant and positive gain for one that is only prospective and uncertain. We have seen that the obstacles which oppose themselves to correctly and satisfactorily determining either the light or the load draughts of water, are sufficient to prevent the difference between the light and load displacements from being taken to represent the tonnage. This is, however, the only correct measure of a ship's power to carry cargo; the difference being, of course, exactly equal in weight to the cargo which either has or may cause it. All other quantities which can be taken as measures of that power are little more than assumptions, and whether they represent the external dimensions of a ship, or her internal capacity, they scarcely give an approximation even to the power which she may possess of carrying burthen; while, in either of the above cases, the fact that these quantities must be determined by measurements at fixed measuring places, affords opportunity for evasion, and indeed invites it. For if, by any arrangement of the dimensions, or by any peculiarity of the shape, a ship can be enabled to carry a greater burthen than her registered tonnage, the freight of that greater burthen is a premium which is offered to that one proportion between her dimensions, or that one peculiar form for her body, and a restriction is, to a certain extent, placed upon improvement; because the ship-owner will content himself with the best ships that he can obtain, possessing the advantages of those dimensions or of that form.

The present rule for computing the tonnage assumes it to be the space for stowage, and the internal capacity of the vessel is calculated in order to determine it. As there are necessarily fixed measuring places, the rule may, as we have said, be evaded by a certain build. Its phraseology may also be most easily evaded by building accommodations on deck, which will not come within the meaning of the terms that are used in it—"poop," "half-deck," or "break in the deck." Under its operation vessels may also be advantageously built of very small register tonnage to carry cargoes of heavy goods; for which purpose they should be of the lightest materials, but with very large scantlings, that the internal capacity may bear but a small proportion to the load displacement of the vessel. We have already however stated, that in its effects the present rule is far less injurious to the mercantile navy of England, than that which it is intended eventually wholly to supersede.

Rule for calculating the Tonnage of Ships or Vessels, as prescribed by Act of Parliament.

The tonnage of every ship or vessel required by law to be registered shall, previously to her being registered, be measured and ascertained while her hold is clear, and according to the following rule: (that is to say), divide the length of the upper deck between the after part of the stem and the fore part of the stern-post into six equal parts. Depths—at the foremost, the middle, and the aftermost of those points of division, measure in feet and decimal parts of a foot the depths from the under side of the upper deck to the ceiling at the limber strake. In the case of a break in the upper deck, the depths are to be measured from a line stretched in a continuation of the deck. Breadths—divide each of those three depths into five equal parts, and measure the inside breadths at the following points: videlicet, at one fifth and at four fifths from the upper deck of the foremost and aftermost depths, and at two fifths and four fifths from the upper deck of the midship depth. Length—at half the midship depth measure the length of the vessel from the after part of the stem to the fore part of the stern-post; then to twice the midship depth add the foremost and the aftermost depths for the sum of the depths; add together the upper and lower breadths at the foremost division, three times the upper breadth, and the lower breadth at the midship division, and the upper and twice the lower breadth at the after division, for the sum of the breadths; then multiply the sum of the depths by the sum of the breadths, and this product by the length, and divide the final product by three thousand five hundred, which will give the number of tons for register. If the vessel have a poop or half deck, or a break in the upper deck, measure the inside mean length, breadth, and height, of such part thereof as may be included within the bulkhead; multiply these three measurements together, and dividing the product by 92·4, the quotient will be the number of tons to be added to the result as above found. In order to ascertain the tonnage of open vessels, the depths are to be measured from the upper edge of the upper strake.

Mode of ascertaining the Tonnage of Steam-Vessels.

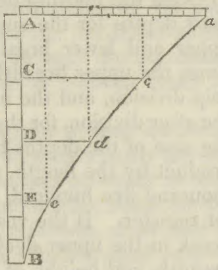
In each of the several rules herein before prescribed, when applied for the purpose of ascertaining the tonnage of any ship or vessel propelled by steam, the tonnage due to the cubical contents of the engine-room shall be deducted from the total tonnage of the vessel, as determined by either of the rules aforesaid, and the remainder shall be deemed the true register tonnage of the said ship or vessel. The tonnage due to the cubical contents of the engine-room shall be determined in the following manner: that is to say, measure the inside length of the engine-room in feet and decimal parts of a foot, from the foremost to the aftermost bulkhead: then multiply the said length by the depth of the ship or vessel at the midship division, as aforesaid, and the product by the inside breadth at the same division, at two fifths of the depth from the deck, taken as aforesaid, and divide the last product by 92·4, and the quotient shall be deemed the tonnage due to the cubical contents of the engine-room.

For ascertaining the Tonnage of Vessels when laden.

And be it further enacted, that for the purpose of ascertaining the tonnage of all such ships, whether belonging to the United Kingdom or otherwise, as there shall be occasion to measure while their cargoes are on board, the following rule shall be observed and is hereby established: that is to say, measure, first, the length on the upper deck, between the after part of the stem and the fore part of the stern-post; secondly, the inside breadth on the under side of the upper deck, at the middle point of the length; and, thirdly, the depth from the under side of the upper deck, down the pump-well, to the skin; multiply these three dimensions together, and divide the product by 130, and the quotient will be the amount of the register tonnage of such ships.

To form a Scale of Tonnage, or a Scale of Displacements.

In order to form what is sometimes called a scale of tonnage, and sometimes a scale of displacement, on the plan of a ship's body draw a horizontal line to represent her load water-section, and beneath this line draw other horizontal lines equidistant from each other, representing equidistant horizontal sections; then calculate the solid contents of the part of the body intercepted between each two successive sections. The sum of the contents of all the solids will be the load displacement of the ship, and the sum of the contents of all the solids below any one of the horizontal sections will be the displacement of the ship up to that horizontal section. Find in this manner the load displacement, and also the displacement up to every horizontal section; then draw a vertical line AB, and on AB, graduated to some scale of feet, set off the distance AB equal to the mean load draught of water of the ship, and on the same line AB let the points C, D, E, be taken respectively at the heights of the other equidistant horizontal sections; then from A, C, D, E, draw A*a*, C*c*, D*d*, E*e*, so that E*e*, D*d*, C*c*, and A*a*, shall respectively be in the same ratio to each other in length as are the solid contents, or the displacements of the parts of the body below the respective horizontal sections, to each other, in cubical contents. Thus, if the solid content of the whole displacement be double the solid content of the displacement up to the height C, then draw A*a* double the length of C*c*; or if it be only one third more, then let A*a* be one third longer than C*c*; and on the same principle with the other lines. Then trace a curve through all the points *a*, *c*, *d*, *e*, which curve will be the curve of displacements. Then, if A*a* be graduated by projecting all the points *c*, *d*, *e*, &c. on to it, the line A*a* will become a scale of displacement, or of tonnage.



The use of the scale is obvious, as, when the ship from which it was formed is at any draught of water within the limits of the height BA, her displacement at that draught may be immediately known by squaring a line out from its height, set off from B on the scale BA, to intersect the curve B*edca*, and then squaring up this point of intersection to the scale of tonnage A*a*, which will be intersected at the number of tons in the displacement required. The effect to be produced in the draught of water by lightening or loading the ship to any extent embraced within the scale may also be easily ascertained; and, in the same manner, the quantity of lading which a ship will require to be put into or taken out of her to bring her to any certain draught of water, may be immediately known. In fact, so useful are these scales of tonnage that they ought to be calculated for every merchant-ship, and a scale drawn and placed in the hands of the commander. It would enable him to answer at once innumerable questions which are completely beyond his knowledge without it. Mr Parsons, a member of the late School of Naval Architecture, proposed to the committee from which the law for tonnage that is at present in force has emanated, that, for all new vessels built or launched after a certain date, such scales of tonnage should be formed, which, when properly authenticated, should be attached to the register of the vessel, in order that from these scales the true tonnage or actual weight of the cargo might be ascertained, and either the whole or any portion of it which the committee might have determined, be taken as the register tonnage. There would have been many difficulties opposed to the practical application of this plan, although we can by no means consider them as insurmountable. Among these difficulties would have been the question as to what is or what ought to be considered as the light draught of water; and also the circumstance that many vessels are built from eye alone, of which, therefore, there would have been no drawings to form the scales of tonnage. Mr Parsons has traced the curves of tonnage for many classes of merchant-vessels, and for the several rates of men-of-war, and has published them in a work called Scales of Displacement. A somewhat similar work, as respects the men-of-war, and under the same title, has also been published by Mr Edye, the assistant-surveyor of her majesty's navy.

A very useful body of information on merchant-vessels resulted from the labours of the committee on tonnage, that has been already so frequently mentioned in this article. It is a valuable and extensive collection of particulars as to the form, proportions, dimensions, and tonnage of the mercantile navy of England. The measurements were all made, and the information was collected and arranged, by Mr Cradock, a member of the late School of Naval Architecture, who was, by the permission of the Lords Commissioners of the Admiralty, employed under the directions of the committee. In order that such a body of information may be more generally useful than it can possibly be while confined to the pages of a parliamentary Report, we shall enrich this article with it. The following accounts of the various methods of computing the tonnage, which are in use among the maritime nations of Europe, were obtained by her majesty's government officially from the several powers, and are included in the report of the committee.

Methods at present in use among Foreign Nations for computing the Tonnage of Ships.

France.—The three measures of length, breadth, and depth, are multiplied together, and the product is divided by 94 for the tonnage.

In single-decked vessels the length is taken from the after part of the stem on deck to the stern-post; the extreme breadth is taken, being measured inside from ceiling to ceiling, and the depth from the ceiling to the under surface of the deck.

In vessels of two decks, at Bordeaux, the length of the upper deck and that of the keelson is measured, and the mean taken for the length. But at Brest, Marseille, and Boulogne, the mean of the length on the two decks from the stem to the stern-post is taken as the length. The depth of the hold from the ceiling to the under surface of the lower deck is added to that of the height between decks, and considered as the depth. The extreme inside breadth is taken in the same way as in single-decked vessels.

At Bordeaux an allowance is sometimes made for the rake of the stem and stern of the vessel.

At Boulogne, in measuring steam-boats, the length of the coal and engine chambers is deducted from the length of the vessel, and her breadth is taken at the fore and aft extremities of the same, the mean of which is considered as the breadth. The depth is taken inside the pumps, from the lower surface of the deck, between the timbers.

At Brest, measures are frequently taken with a string, although contrary to law, and an error of seven tons in the tonnage of a cutter has been the result.

SPAIN.—Three breadths are measured at the following places: 1st, at the mizen-mast; 2d, a few feet abaft the foremast; 3d, at a point half way between the two former. The heights at which the three breadths are taken at the above places are, 1st, on a level with the deck; 2d, on a level with the upper surface of the keelson; 3d, at a level half way between the two former positions.

To find the area at each section, the half of the sum of the upper and lower measurements is added to the middle measurement, and this sum is multiplied by the height of one above the other. Then half the areas of the fore and after section is added to that of the middle section, and this sum is multiplied by the length which the sections are apart from each other. The result will express in Burgos cubic feet the capacity of the part of the hold between the fore and after sections, and it still remains to add the spaces between these and the stem and stern-post. The former may be found, without any considerable error, by multiplying the area of the foremost section by half its distance from the stem; and the latter in the same manner, by multiplying the area of the after section by half its distance from the stern-post. It is evident that the room occupied by the pumps must be deducted from the foregoing result, in order to obtain the fair quantity of space filled by the cargo.

Having thus found the capacity of the hold of any vessel in the above manner in Burgos cubic feet, it is to be divided by $41\frac{61}{779}$, and the result will be the amount of displacement of such vessel in tons of Burgos measure, because each ton is reckoned equal to $41\frac{61}{779}$ feet of Burgos.

PORTUGAL.—*For single-decked vessels*, the length is measured from the cabin bulkheads to the forecastle bulkheads. The depth is measured from the upper surface of the keelson to the under surface of the beams. The extreme breadth of the deck is considered the breadth. The continued product of these three dimensions will give the contents in cubic feet, which, divided by $57\frac{726}{1000}$, gives the tonnage.

Vessels of two decks. In these vessels two distinct operations are made; one for the hold, the other for the middle deck. For the hold:—The length is measured from the heel of the bowsprit to the stern-post. The breadth is the extreme breadth of the upper deck, deducting two feet. The depth is from the upper surface of the keelson to the under surface of the beams. For the middle deck:—The length is considered as half of that for the hold, the other half being allowed for cabins, &c. The breadth as before; and for the depth, the height of the middle deck to the under surface of the beams.

The foregoing is the method adopted at Lisbon, but at Oporto the length of the vessel is taken from the second timber at the bows to the stern-post; the breadth, at the widest part from the inside of each bulwark on the upper deck; and the depth, from the upper surface of the keelson to the lower surface of the beams of the upper deck at the main hatchway.

If the keelson be more than ordinarily thick, allowance is made accordingly; and where there are two decks, the thickness of the lower deck is also deducted from the depth. The length is then multiplied by the breadth, and the product by the depth. This product is then divided by 96, the number of Portuguese cubic feet contained in a ton, and the result is the tonnage of the vessel.

NAPLES.—*For vessels with two decks*, the length is measured from one end of the vessel to the other, *over all.* The length is also measured from the after part of the stem to the rudder hatch, under the poop. The mean between these two lengths is multiplied by the extreme breadth of the vessel.

The depth is then taken from the bottom of the well to the lower surface of the upper or poop deck; and the above product being multiplied by this depth, and divided by 94, gives the tonnage.

For single-decked vessels, the tonnage is found by multiplying the extreme length by the extreme breadth, and the product by the extreme depth, and dividing by 94, as above.

NETHERLANDS.—The length is measured on deck from the stem to the stern-post. For the breadth, the hold is divided into four portions, and two measurements taken at each of the three divisions: 1. Across the keelson, on a level with its upper surface, from ceiling to ceiling: 2. The greatest breadth of the hold at each division. The mean of these six measurements is considered the breadth.

The depths are taken at each of the foregoing points of division, from the upper surface of the keelson to the lower surface of the upper deck between the beams, and the mean of these three is assumed.

The length, breadth, and depth are then multiplied together, and two thirds of the product is considered as the tonnage. But an allowance for provisions and water, cabins, and ship's stores, varying from $\frac{30}{100}$ to $\frac{45}{100}$, is deducted from the depth before it is multiplied by the length and breadth.

NORWAY.—From the after part of the stem, the length of the ship is taken to the inner part of the stern-post. Dividing the length of the vessel into four equal parts, the breadth is measured at each of these divisions. The depth of the vessel, from the under surface of the upper deck to the keelson, is taken at the above three points of division.

Then multiply the length by the mean of the three breadths, and this product by the mean of the three depths.

The result of the foregoing is divided by $242\frac{1}{2}$, if there be no fractional parts of feet; but if there are, the calculation is made in inches, and the divisor becomes 322·767, the result thus obtained being the burthen of the vessel in wood lasts of 4000 Neva pounds each. To reduce these into commerce lasts, one of which is equal to 5200 Neva pounds, it is multiplied by 10, and divided by 13.

RUSSIA.—Length of the keel in feet, multiplied by the extreme breadth over the sheathing, and the product multiplied again by half the breadth, and divided by 94, gives the number of English tons.

UNITED STATES.—If the vessel be double-decked, the *length* is taken from the fore part of the main stem to the after part of the stern-post, above the upper deck; the *breadth*, at the broadest part above the main wales, half of which breadth is accounted the *depth.* From the length *three fifths* of the *breadth* is deducted; the remainder is multiplied by the *breadth*, and the product by the *depth.* The last product is divided by 95, and the quotient is deemed the true tonnage of such ship or vessel.

If the ship or vessel be single-decked, the *length* and *breadth* are taken as above for a double-decked vessel, and three fifths of the breadth are deducted from the length. The depth of the hold is taken from the under side of the deck-plank to the ceiling in the hold. These are multiplied and divided as aforesaid, and the quotient is the tonnage.

At Philadelphia a system of measuring, called carpenter's tonnage, appears to be adopted. The rule is as follows.

For vessels with one deck, multiply the length by the breadth of the main beam, and the product by the depth. Divide this second product by 95.

For double-decked vessels, take half the breadth of the main beam for the depth, and work as for a single-decked vessel.

At New Orleans the mode at present in use is as follows.

Take the length from the stem to the after part of the stern-post, on the deck. Take the greatest breadth over the main hatch, and the depth from the ceiling of the hold to the lower surface of the deck at the main hatch.

From the length deduct $\frac{3}{5}$ths of the breadth, multiply the remainder by the actual breadth and depth, and divide by 95, for a vessel with a single deck; but if the vessel have a double deck, half the breadth of the beam is considered as equivalent to the depth, and is multiplied accordingly. (B Z.)

MR CRADOCK'S MEASUREMENTS OF MERCHANT SHIPPING,

85. Weight of ballast, in tons, carried with the above cargo,		270	125	35	None.	85.
86. Weight of billet-wood or dunnage, &c. in tons, which is used for stowing the cargo,		None.	None.	15	10	86.
87. From whence she came,		Canton.	Canton.	Calcutta.	Calcutta.	87.
88. The whole internal solid content, in cubic feet, from the under surface of the upper deck, without any deductions whatever,		151,922	112,689	64,133	56,050	88.

(a) At upper part of the deck below the upper deck.
(b) At 4 feet below the upper deck.
(c) At 8 feet below the same deck.
(d) At lower part of platform
(e) At 4 feet below the under part of the deck.
(f) At 8 feet below the deck
(g) At 12 feet below the deck.
(h) At under part of lower deck.
(i) At 5 feet below the lower deck.

In this article we have described the method of constructing a scale of Tonnage, or of Displacements. The manner of performing the calculations to ascertain the displacement of a ship has been explained in the article Ship-building; it is therefore unnecessary to recapitulate it here. Many persons, merely for want of sufficient attention to such explanations, are unable to perform these arithmetical calculations, and hence the frequent great errors in the displacements of ships. The following experimental method of ascertaining, very nearly, the actual tonnage of a ship, may not therefore be altogether useless. In fact, we suggest it with the impression that it may be advantageously followed by merchant-builders.

Suppose a model of a vessel to be made on a scale of half an inch to a foot, then each cubic inch will represent eight cubic feet. A cubic inch of sea-water weighs ·594 of an ounce, that is, eight cubic feet of sea-water on a half inch scale weigh ·594 of an ounce. Therefore each ton, reckoning 35 cubic feet of sea-water to the ton, will weigh 2·5987 ounces, or 5 tons will very nearly weigh 13 ounces, and will measure in bulk 21⅞ cubic inches.

If a box be made to a half-inch scale, 175 feet long and 40 feet wide, interior dimensions, rectangular every way, of wood varnished, and with the end grain of the wood in the direction of the given dimensions, each ⅛ of an inch in depth of such a box will be 218¾ cubic inches, which, according to the foregoing scale, will be 50 tons in weight.

To use this box, fill it partly with sea-water, then take the model of the vessel, which is of course supposed to be of dimensions less than those of the box. It is presumed that the launching weight is known. Suppose this, for example, to be 45 tons. Let the model float on the water, having previously observed the depth of water in the box. Load the model until the water has risen 9/80 of an inch above this observed depth, the model then evidently floats at its mean launching draught of water.

The load draught of water at which the vessel should swim is known. Load the model until it is brought to this water-line, and observe

the rise of water in the box, remembering that every $\frac{1}{8}$ of an inch rise in the box indicates 50 tons increase to the displacement of the vessel. Thus suppose, when the model swims at the draught of water wished for the vessel, that the water has risen an additional $\frac{1}{4}$ of an inch more than at the launching draught of water; as it is known that the vessel will carry 50 tons for every $\frac{1}{8}$ of an inch rise in the box, she will evidently carry 100 tons of cargo at the draught of water to which she now swims.

An additional advantage may be gained by observing the weights used according to the scale already mentioned, that is, 13 ounces to represent 5 tons. It is, that the vessel's lading may be so apportioned as to bring her to the exact trim forward and aft that may be wished.

Suppose, for instance, a steam-boat to carry a 35 horse power engine; place 91 ounces at the centre of weight given by the engineers in the space allotted for the engine-room; then apportion the other weights, as crew and effects, ship's stores, cargo, &c. over the respective spaces allotted for their reception. It will be seen whether the vessel, as formed, will bear them there, and swim at the trim intended; if not, either the vessel, the weights, or the trim, must be altered.

In consequence of the minuteness of the scale, and of the difficulty of observing it on account of the attraction of cohesion of the water, it would be better, and very easy, to have an index, or rather two, one forward and the other abaft, moving on a fulcrum over the edge of the box, and pointing to a graduated arc, which might, by lengthening the index-arm of the lever, indicate to any degree of exactness or minuteness required. Of course the inner arm of the lever would rise and fall with the model.

The foregoing remarks will only apply to a box of the exact dimensions given, that is, one of which every $\frac{1}{8}$ of an inch in depth will give a solid content of sea-water, weighing, according to the scale, 50 tons, under the supposition that a cubic inch of water weighs ·594 of an ounce. If other than sea-water is to be used, a different calculation must be made. The water used should be that in which the vessel is to be navigated.

TONNAGE and POUNDAGE, an ancient duty on wine and other goods, the origin of which seems to have been this. About the 21st of Edward III. complaint was made that merchants were robbed and murdered on the seas. The king thereupon, with the consent of the peers, levied a duty of 2s. on every ton of wine, and 12d. in the pound on all goods imported; which was treated as illegal by the commons. About twenty-five years after, the king, when the knights of shires were returned home, obtained a like grant from the citizens and burgesses, and the year after it was regularly granted in parliament. These duties were sometimes diminished and sometimes increased; at length they seem to have been fixed at 3s. tonnage and 1s. poundage. They were at first usually granted only for a stated term of years, as, for two years in 5 Ric. II.; but in Henry VI.'s time they were granted him for life by a statute in the 31st year of his reign; and again to Edward IV. for the term of his life also: since which time they were regularly granted to all his successors for life, sometimes at the first, sometimes at other subsequent parliaments, till the reign of Charles I., when, as Clarendon expresses it, his ministers were not sufficiently solicitous for a renewal of the legal grant. And yet these imposts were imprudently and unconstitutionally levied and taken, without consent of parliament, for fifteen years together; which was one of the causes of those unhappy discontents. The king found it expedient to pass an act, whereby he renounced all power in the crown of levying the duty of tonnage and poundage, without the express consent of parliament; and also all power of imposition upon any merchandises whatever. Upon the restoration, this duty was granted to King Charles II. for life, and so it was to his two immediate successors; but by three several statutes, 9 Ann. c. 6, 1 Geo. I. c. 12, and 3 Geo. I. c. 7, it is made perpetual, and mortgaged for the debt of the public.

TONNEINS, a city of France, in the department of the Lot and the Garonne, and in the arrondissement of Marmande. It is on a fertile plain on the right bank of the Garonne, along which its broad well-built streets extend to a great length. The inhabitants amounted in 1836 to 6494. They cultivate much tobacco and hemp, but the city has now very few manufactures.

TONNERE, an arrondissement of the department of the Yonne, in France. It extends over 463 square miles, and comprehends five cantons, divided into eighty-two communes, having 45,390 inhabitants in 1836. Its capital is the city of the same name, situated on the river Armançon, and containing in the same year 4271 inhabitants. They make much good wine, and carry on manufactories of hats and hosiery. Long. 3. 53. 39. E. Lat. 4. 51. 8. N.

TONNINGEN, a city of Denmark, in the province of Sleswick. It is on a hill on the right bank of the river Eyder, and near its mouth. From its connection with the Sleswick Canal, which unites the German Ocean with the Baltic, it has some trade; but had more during the war, when it was a depot for colonial articles. It now contains 2180 inhabitants. Long. 8. 43. E. Lat. 55. 19. N.

TONORU, a town in the province of Mysore, where are still to be seen the remains of ancient and extensive walls, that must have enclosed a large city. The town, which is decayed, is fast increasing in size and population under the British government.

TONQUIN. See TUNQUIN.

TONSURE, a particular manner of shaving or clipping the hair of ecclesiastics or monks. The ancient tonsure of the clergy was nothing more than polling the head, and cutting the hair to a moderate degree, for the sake of decency and gravity. The same observation is true with respect to the tonsure of the ancient monks. But the Romans have carried the affair of tonsure much farther. The candidate for it kneels before the bishop, who cuts the hair in five different parts of the head, viz. before, behind, on each side, and on the crown.

TONTINE, a loan given for life annuities with benefit of survivorship; so called from the projector Lorenzo Tonti, a Neapolitan. He proposed his scheme in 1653, to reconcile the people to Cardinal Mazarine's government, by amusing them with the hope of becoming suddenly rich. He obtained the consent of the court, but the parliament would not register the edict. He made attempts afterwards, but without success. It was not till Louis XIV. was distressed by the league of Augsburg, and by his own immense expenses, that he had recourse to the plans of Tonti.

The nature of the plan is this. An annuity, after a certain rate of interest, is granted to a number of people, divided into classes, according to their respective ages; so that the whole annual fund of each class is regularly divided among the survivors of that class; till at last it falls to one, and upon the extinction of that life, reverts to the power by which the tontine was erected, and which thus becomes security for the due payment of the annuities.

TON-TING, a large lake of China, in the province of Houquang, about sixty miles long, and from seventeen to twenty-five broad.

TONYN'S ISLANDS, a cluster of small islands in the Eastern Seas, near the south-west coast of the island of Celebes. Long. 119. E. Lat. 5. 31. S.

TOOBAE, some very low islets about five miles north of Bolabola, one of the Society Islands, much resorted to for turtle, found in great abundance on its shores.

TOOBIGAN, a small island in the Sooloo Archipelago. Long. 120. 44. E. Lat. 6. 14. N.

TOOBOUAI ISLAND, one of the Society Islands, in the South Pacific Ocean, about six miles in extent. Long. 210. 37. E. Lat. 23. 25. S.

TOOFOA, one of the Friendly Islands, visible from Annamooka. It was from this island that Lieutenant Bligh was forced into his boat with eighteen of his people.

TOOKE, JOHN HORNE, an ingenious grammarian, and an active politician, born in Westminster, June 1736, was the son of Mr John Horne, a poulterer living in Newport Market. He was the third of seven children; but his father, having acquired considerable affluence, first sent him for a short time to Westminster school, and then to Eton, where he remained five or six years without particularly distinguishing himself, and was removed sooner than had been intended, on account of the accidental loss of an eye. In 1755 he went to St John's College, Cambridge, where he took the degree of A.B. He then became an usher in a school at Blackheath, kept by Mr Jennings; but he was soon after induced by his father to take deacon's orders, and obtained a curacy in Kent. His own preference, however, was so much in favour of the law, that in 1756 he entered as a student of the Middle Temple; but in 1760 he was persuaded to return to the church, and to receive ordination as a priest; and he officiated for three years in the chapelry of New Brentford, which his father had purchased for him; performing his duties with decency, and taking some pains to study the elements of medicine for the sake of the poorer members of his congregation. He then went as tutor to France with the son of Mr Elwes, a gentleman of Berkshire, well known for his riches and his economy.

In 1765, he commenced his political career by writing an anonymous pamphlet in defence of Wilkes and his party. He returned to the continent, and made the tour of Italy in company with a Mr Taylor; and at Paris he formed an intimacy with Wilkes himself, who then found it convenient to reside there. He had altogether laid aside his clerical character in these excursions, but he resumed it for a short time after his return. Soon, however, he relapsed into his political amusements; exerting himself, with some success, in various elections, as a partisan of his friend Wilkes, and taking up the cause of a Mrs Bigby, in the pursuit of an appeal of blood, against the murderers of her husband, who were supposed to have obtained a pardon through corrupt interest with the court; though the widow at last disappointed him by accepting a pecuniary compensation for her right of appeal. He was however successful, on his own behalf, in repelling a prosecution for a libel on Mr Onslow; and he gained some credit with a party in the city by suggesting to Beckford, then lord mayor of London, the reply which he made to the king's answer to their remonstrance, and which may still be seen engraved on the pedestal of Beckford's statue in Guildhall. He was soon after very active in establishing the society for supporting the bill of rights, and in obtaining the liberation of Bingley, the printer, who had been somewhat hastily committed to prison by Lord Mansfield.

In the year 1770, he had reason to be dissatisfied with the conduct of Wilkes, in some pecuniary transactions relating to the society for the bill of rights. Both parties appeared to the public in a light somewhat ridiculous on the occasion, and neither of them gained in respectability, though the society did not appear to value Wilkes the less for the exposures that took place. It was, however, shortly after dissolved, and most of its members, except the particular friends of Wilkes, were incorporated into the constitutional society. The next year, Mr Tooke completed his academical course at Cambridge, by taking the degree of A. M., though not without some opposition. About this time he exerted himself greatly in procuring the publication of the debates of the House of Commons in the daily papers, notwithstanding the well-known standing orders of the house; and so far as he was instrumental in carrying this point, he appears to have rendered at least one very essential service to his country; but Wilkes, and especially Almon, the bookseller, are said to have a still stronger claim to the merit of this transaction, whatever may have been its character. He had also a sharp contest with the anonymous Junius, against whose hasty attack he defended himself with great spirit and energy, and with unexampled success. In 1773 he made a formal resignation of his living, and meant at the same time completely to lay aside his clerical character, though no person seems to have felt himself authorized to accept this part of his resignation; and he began to study the law very diligently, intending to make it the occupation of his life. He adopted soon after a singular method of forcing himself upon the notice of the public, and of the House of Commons in particular: an enclosure bill being about to be hurried, as was reported, a little too rapidly through the house, he wrote some paragraphs in a newspaper, which reflected very severely on the conduct of the Speaker, on purpose that he might be summoned to appear before the house; and being placed at the bar, he gave such reasons for his conduct as produced some animated discussions, and in the end was supposed, though probably without foundation, to have caused the bill to be modified in some oppressive clauses. By these means he obtained the favour of Mr Tooke of Purley, who thought himself aggrieved by the bill in its original state, and received from him such assurances of testamentary favours as induced his nephew, Colonel Harwood, to agree upon a partition of their joint interest in the reversion of his estate; though Mr Horne never received, first and last, more than L.8000 from the property, notwithstanding the subsequent change of his name about the year 1782, in acknowledgment of his patron's kindness, and his long-continued intimacy and frequent residence at Purley; the principal legatee, after all, being a Mr Beaseley.

Mr Horne Tooke was, of course, a strenuous opposer of the American war; and in 1777, he published a very offensive advertisement, in which the sufferers in the battle of Lexington were described as having been murdered by the king's troops. For this attack on the government, he was tried at Guildhall in July 1777. He conducted his own defence, but was found guilty of the libel, and sentenced to one year's imprisonment in the King's Bench, and a fine of L.200. It was on this occasion that he first appeared before the public as a grammarian, in the criticisms which constitute his celebrated "Letter to Mr Dunning." The next year he suffered a still severer punishment, in the refusal of the society of the Inner Temple to admit him to the bar, on account of his having taken orders; so that his prospects of professional advancement were utterly annihilated. This occurrence made him still more bitter against the existing government, and in 1780 he printed some severe remarks upon the measures of Lord North. He attempted to establish himself as a practical farmer in Huntingdonshire; but he caught an ague, and soon becoming disgusted with an agricultural life, he returned to London, and occupied for some years a house near Soho Square. His ideas of parliamentary reform, contained in a second letter addressed to Mr Dunning, were by no means extravagant, and he continued to adhere, in this respect, rather to the party of Mr Pitt than to that of Mr Fox.

The publication of his grammatical dissertations, under the title of the Diversions of Purley, afforded but a slight and imperfect intermission of his political pursuits, for his etymological works are as replete with the politics of the day as his speeches and his pamphlets. Another of his pamphlets appeared in 1788, under the title of Two Pair of Portraits, being intended to serve the cause of Pitt's party in their elections. But in 1790 he himself became a candidate for the representation of Westminster, in opposition to Mr Fox and to Lord Hood; and he distinguished himself sufficiently as a public orator, though he was not succcessful in the contest.

In 1794, he was tried for high treason, together with several other members of the corresponding societies, who had been active in attempting to introduce some imitations of the French Revolution in the plans of reform which they brought forward. He exhibited on the trial somewhat more of firmness than of good taste. One of his associates had before been acquitted, and the jury speedily returned a similar verdict with respect to himself. He afterwards dedicated the second volume of his Diversions of Purley to his counsel, Gibbs and Erskine, and to the jury who tried him.

In 1796 he again became a candidate for the representation of Westminster, but again without success; and, notwithstanding his strong opinions respecting a reform in parliament, he afterwards condescended to accept from Lord Camelford, in 1801, a seat for the nominal borough of Old Sarum. It was then to be determined if a clergyman could sit in the House of Commons; but the ministry, instead of contesting the point with respect to his particular case, brought in a bill to decide the question in the negative for the future, and he remained in the house till the dissolution of the parliament in the next year, but without particularly distinguishing himself in its proceedings. His last public effort as a party man was made in espousing for a short time the cause of Mr Paull, as candidate for Westminster; but he abandoned this gentleman in a subsequent contest. The later years of his life were chiefly passed in the society of a select circle of friends, who frequently partook of his hospitality at Wimbledon. He died in March 1812, leaving his property to some natural daughters; for he had never been married. He was buried in Ealing church, and not in his garden, as he had directed; his executors thinking themselves the less bound by these instructions, as a literal compliance with them might have been unfavourable to the sale of the property.

1. His earliest publication was a pamphlet entitled The Petition of an Englishman, 1765. It consisted principally of apologies for the private conduct and immoral writings of Wilkes.

2. He also published a Sermon while he continued in the church, that is, before the year 1773; but it attracted little notice.

3. A Letter to Mr Dunning, 1778. The rudiments of his grammatical system, arising out of remarks on the particles employed by the attorney-general in his indictment, and by the judges in his sentence. It was afterwards incorporated into the Diversions of Purley.

4. Facts, 1780; consisting of remarks on the administration of Lord North; with some additions relating to finance, by Dr Price.

5. A Letter on Parliamentary Reform, 1782; addressed to Mr Dunning, afterwards Lord Ashburton.

6. Επεα Πτεροεντα, or Diversions of Purley, 1786, 8vo. Ed. 2, 4to. Part i. 1798. Part ii. 1802. This is his great and celebrated work; rich indeed in etymology and in wit, but meagre in definition and in metaphysics.

7. A Letter to the Prince of Wales, 1787; relating to his supposed marriage with a Catholic.

8. Two Pair of Portraits, 1788, 8vo. The two Pitts contrasted, in opposite columns, with the two Foxes, in colours by no means favourable to the latter.

9. Many of his Letters have been printed in Stephens's Life of Tooke.

It is from the last-mentioned publication that this historical sketch of Mr Tooke's life has principally been extracted. It now becomes necessary to add some remarks on his literary and moral qualifications; and in both these points of view the subject has been treated in so masterly a manner by the author of an article in the Quarterly Review, who is supposed to be a near relation of Tooke's most intimate friend, the late Colonel Bosville, that it would be presumption in any man to go over the same ground, without adopting very nearly the eloquent and energetic expressions which that noble and learned person has employed.

"Mr Tooke," says the accomplished reviewer of the Memoirs of his Life (Q. R. vol. vii. p. 325), "was possessed of considerable learning, as indeed his writings sufficiently show. To other more casual acquirements, he united a very extensive acquaintance with the Gothic dialects, of which he has so copiously and so judiciously availed himself in his etymological researches." But it must be remarked, that a person more intimately acquainted with the "Gothic dialects" as living languages, will easily discover that his knowledge of them was in truth but superficial, or that he was indebted for it more to grammars and dictionaries, than to any extensive study of the authors who had written in those languages, or to any habit of speaking them; and such a person will easily find a variety of instances, in which a very different etymon to that which he has assigned, will naturally suggest itself as the true origin of the word in question.

(P. 320.) "Though Mr Tooke's philosophical works are the results of no common talent and industry, yet they are neither written in a truly philosophical spirit, nor do they display traces of a mind which, even if it had been wholly dedicated to the study of metaphysics, would have much enlarged the bounds of our knowledge in that nice and intricate branch of science. His object seems to have been rather to retard than to advance the progress of philosophy, by recalling us from those sound conclusions as to the nature and operations of the human mind, which are built upon observation and experience, to vague speculations, drawn from the imperfect analogy existing between the moral and the physical world. There can be no doubt that the proposition which he has succeeded in establishing is highly interesting and important; and that in the illustration of it he has shown great learning, ingenuity, and research. But then, on the other hand, he has so monstrously exaggerated its importance, and so widely mistaken its tendency, and has attempted to raise so vast a superstructure upon such a narrow, slippery, and inadequate foundation, that we are quite lost in amazement when we recollect how completely the sagacity which guided him so well in the investigation of his principal fact, appears to desert him when he comes to apply that fact to the purposes of a theory. The distance between what he has proved and what he wishes us to believe that he has proved, is enormous. What he has proved is, that all words, even those that are expressive of the nicest operations of our minds, were originally borrowed from the objects of external perception; a circumstance highly curious in the history of language, consequently in the history of the human mind itself, and the complete demonstration of which, of course, reflects great credit upon its author. What he thinks he has proved is, that this etymological history of words is our true guide, both as to the *present* import of the words themselves, and as to the nature of those things which they are intended to signify; a proposition so monstrous that he has nowhere ventured to enunciate it in its general form, but has rather left it to be collected from the tenor of his remarks upon particular instances. In truth, the inferences at which Mr Tooke arrived, far from being warranted by his facts, are directly the contrary of those to which he ought naturally to have been led by the result of his own studies, when they were most successful. In tracing upwards, through all the mazes of etymology, the origin of words, he ought to have seen more clearly, if possible, than any body else, that their *real present* sense is not to be sought for in their primitive signification, or in the elements of which they were originally composed, but that, on the contrary, their *actual import*, with which alone in reasoning we have to do, hardly ever corresponds with their etymological meaning, although the one always bears to the other a certain resemblance, more or less accurate, according to the greater or less effect of time and accident. One could without difficulty understand how a person, unaccustomed to such considerations, and misled by a few instances partially chosen, should adopt a theory like that which Mr Tooke was desirous to establish; but how a philosopher, minutely acquainted with the whole subject, and proceeding upon a most copious induction of particulars, should not have perceived that, in ninety-nine instances out of a hundred, such a doctrine would lead to absolute absurdity, is, to us at least, inconceivable."

The reviewer then follows Mr Dugald Stewart in some very just criticisms, which this distinguished philosopher had already made on several of Mr Tooke's examples, fully proving the complete fallacy of the system which so completely confounds the definition of a term with its etymology. Mr Tooke has indeed the merit of having demonstrated pretty clearly that all the parts of speech, including those which grammarians had often considered as expletives and unmeaning particles, may be resolved more or less completely into nouns and verbs; but, on the one hand, it has been observed, that the very same doctrine may be clearly traced back to the works of Aristotle; and, on the other, it may be asserted with equal truth, if we wish to carry the theory to its utmost extent, that language consists only of nouns and *one verb;* since all verbs may in fact be resolved into participles or adjectives, compounded with auxiliary verbs, as well as those which exhibit this complication in their exterior form.

"In the ordinary intercourse of life, Mr Tooke was kind, friendly, and hospitable." (P. 325.) We doubt whether his temper was naturally good; but if it was not, he had a merit the more; for he had so completely subdued it by care and self-control, as never to betray, under any provocation, the slightest mark of that irritability which often accompanies talent, and which gains so rapidly upon those who know not how to guard against its approaches. Indeed the aspect under which he appeared in private was by no means such as the stern cynicism and ferocious turbulence of his public conduct would have led one to expect; and those whose opinion of him has been formed exclusively upon his political character and his writings, will have some difficulty in believing that the curate of Brentford was one of the best bred gentlemen of that age. In this respect he was a sort of phenomenon. He was born in a low station; at no period did he appear to have possessed any remarkable advantages for the study of good breeding; on the contrary, the greater part of his life was spent in constant intercourse with coarse, vulgar, and uneducated men; yet his natural taste was so good, and he had profited so judiciously by whatever opportunities he enjoyed, that courts and high stations have seldom produced a better example of polite and elegant behaviour, than was exhibited by the associate of Messrs Hardy and Thelwall. Indeed his manner had almost every excellence that manner can display; grace, vivacity, frankness, dignity. Perhaps, indeed, in its outward forms, and in that which is purely conventional, his courtesy wore the air of the *vieille cour*, and was rather more elaborate than is consistent with the practice of this lounging unceremonious age; but it was never forced or constrained, and it sat not ungracefully upon an old man." It may however deserve to be remarked, in contemplating this paradox, though rather as a collateral coincidence than as a satisfactory explanation, that even from his infancy Tooke had actually seen something of the very highest society, having been admitted once or twice a week at Leicester House as a play-fellow to George the Third; and though he may have learned but little from imitation of the manners of the young prince, yet the early habit of self-restraint imposed by such a presence, may easily have imprinted some courtly traces on his character, which were not easily effaced, and which an association with the heirs of the first families of the kingdom, throughout his boyhood, at Westminster and at Eton, must naturally have made still more distinct and permanent.

"He never appeared to greater advantage than in conversation. He possessed an inexhaustible fund of anecdotes, which he introduced with great skill, and related with neatness, grace, rapidity, and pleasantry: he had a quick sense of the ridiculous, and was a great master of the whole art of raillery, a dangerous talent, though the exercise of it in his hands was always tempered by politeness and good humour."

"In spite of labour and dissipation (p. 328), his life was protracted to a period which indicated an originally sound and vigorous frame. For the last twenty years, however, he was subject to several severe, distressing, and incurable infirmities. These he bore with a patience and firmness which it was impossible not to admire: to the very last he never suffered himself to be beaten down by them, nor ever for one moment indulged in complaint, or gave way to despondency. In the intervals of pain, nay, even when actually suffering under it, he preserved a self-command, which enabled him to converse, not only with spirit and vigour, but with all his accustomed cheerfulness and pleasantry; never making any demand upon the sympathy of his friends, or mentioning his own situation at all, except when occasionally, and by a very pardonable exercise of his sophistry, he amused himself in exalting its comforts, and explaining away its disadvantages; displaying, in this respect, a manly spirit and a practical philosophy, which, if they had been brought to bear upon his moral as well as upon his physical condition, if they had been employed with as much effect in reconciling him to his political exclusion as to his bodily sufferings, might have produced, not the very imperfect character we have been attempting to delineate, in which the unfavourable traits bear so large a proportion to those of a nobler and more benign cast, but the venerable portrait of a truly wise and virtuous man."[1] (L. L.)

TOOL, among mechanics, denotes in general any instrument used for making other complex instruments and machines, or in other operations of the mechanic arts.

TOOLJAPOOR, a town of Hindustan, in the province of Aurungabad, 110 miles south-east from Ahmednuggur. This place contains a number of small pagodas dedicated to the goddess Bhavani.

TOOLOOMBAH, a town in the Afghan territories, in the province of Mooltan, situated on the south side of the Ravey river, sixty miles north-east by east from the city of Mooltan. Long. 72. 13. E. Lat. 30. 58. N.

TOOMBUDDRA, a celebrated river of the south of India, which takes its name from the junction of the Toom and the Bhadra, which rise in the western mountains. After flowing through a jungly country for nearly a degree, it joins its name and waters with the Tunga at Koorly. From thence taking a sweep, first northerly, and then westerly, and afterwards to the east, it continues a winding course until it falls into the Krishna, skirting the north-western frontier of the British dominions.

TOOMOON, a small town of Hindustan, in the province of Malwah, eighty-four miles west by north from Chatterpoor. Long. 78. 35. E. Lat. 25. 8. N.

TOOREYPOOR, a town of Hindustan, in the Carnatic, twenty-four miles north from Trichinopoly. Long. 78. 48. E. Lat. 11. 11. N.

TOORMOOZ, TIRMOZ, or TERMED, a city of Independent Tartary, situated to the north of the Oxus, near its junction with the Hissaur river. It is fifty miles north of Balkh.

TOOTING, a large village of the county of Surrey, in the western division of the hundred of Brixton, six miles from London. It consists of many seats of the richer merchants and gentry of the metropolis. It has a church, remarkable from being of a circular form. The river Wandle passes through the parish, and turns mills as well for grinding corn as for other mechanical operations. There is also a hamlet near it called Upper Tooting. The population amounted in 1821 to 1863, and in 1831 to 2063.

TOP, a sort of platform, surrounding the lower masthead, from which it projects on all sides like a scaffold. The principal intention of the top is to extend the topmast shrouds, so as to form a greater angle with the mast, and thereby give additional support to the latter. It is sustained by certain timbers fixed across the hounds or shoulders of the masts, and called the *trestle-trees* and *cross-trees*. Besides the use above mentioned, the top is otherwise extremely convenient to contain the materials necessary for extending the small sails, and for fixing or repairing the rigging and machinery with more facility and expedition. In ships of war it is used as a kind of redoubt, and is accordingly fortified for attack or defence; being furnished with swivels, musketry, and other fire-arms, and guarded by a thick fence of corded hammocks. Finally, it is employed as a place for looking out, either by day or night.

TOPMAST, the second division of a mast, or that part which stands between the upper and lower pieces.

---

[1] Stephens's Memoirs of John Horne Tooke. Lond. 1813, 2 vols. 8vo. Quarterly Review, vol. vii. p. 320. British Critic, N. S. vol. i. p. 79, 193. Aikin's General Biography, vol. ix. p. 449. Chalmers's Biographical Dictionary, vol. xxix. p. 449.

TOPGALLANT Isle, a high and rocky island, of little extent, with three rocks near it, lying off the southern coast of New Holland, between 134° and 135° east longitude.

TOPOGRAPHY, a description or draught of some particular place, or small tract of land, as that of a city or town, manor or tenement, field, garden, house, castle, or the like.

TOPSAILS, certain large sails extended across the topmasts, by the topsail yard above, and by the yard attached to the lower mast beneath; being fastened to the former by robands, and to the latter by means of two great blocks fixed on its extremities, through which the topsail-sheets are inserted, passing from thence to other two blocks fixed on the inner part of the yard close by the mast; and from these latter the sheets lead downwards to the deck, where they may be slackened or extended at pleasure.

TOPSHAM, a town of the hundred of Wonford, in the county of Devon, 170 miles from London. It stands on the river Exe, about three miles below Exeter, and is the place where the vessels to that place are anchored. The upper part of the town is pleasant and well built, but not the lower part, which is chiefly inhabited by sea-faring people. The inhabitants amounted in 1821 to 3156, and in 1831 to 3184.

TOR, an ancient town of Arabia, near the head of the Red Sea, and once a place of importance, and a great emporium of Indian trade. It has been supplanted by Suez, and has now sunk to a mere village. The harbour is formed by a reef of coral rocks, and to the northward by a low point of land, on which is placed a beacon. The population consists of Greeks and Bedouin Arabs; and here is also a convent of the monks of Mount Sinai, to which they sometimes retire. It has good water, better than any which is found on the Red Sea; but there are no other refreshments nearer than Sinai. Long. 33. 28. E. Lat. 28. 19. N.

TORBAY, a fine and commodious bay on the coast of Devonshire, of great importance to the naval power of the British empire, celebrated as the place where King William with his army landed in the year 1688. The bay is formed by two capes or promontories; that on the east, called Hob's-nose, and that on the west, called Berry-head. It is distant from the Bill of Portland thirty-seven miles, and the circumference is about twelve miles, so that there is sufficient space for the whole British navy to ride in security. Near the entrance are four islets or large rocks, called the Oristone, the Loadstone, the Thatcher, and the Shag-rock; but they present no danger, as there is a good passage between them, and a depth from six to ten fathoms of water close to them. Ships may anchor in this bay in six, seven, eight, or nine fathoms water. The ground is a strong clay, and very good for holding. Within the bay they are secure against all winds; but a gale from the east brings in a great swell, which ships can avoid by anchoring about a mile from Brixham pier-head, in seven fathoms of water.

Few parts of England so powerfully strike the beholder as this bay when viewed from a ship at anchor in it. The thick foliage of the fruit and other trees which are distributed on the sides of the lofty hills that surround the bay, the elegant gentlemen's seats interspersed among them, the villages with the spires of the churches on the land, the two towns of Brixham and Torquay with their handsome rows of houses, and the great number of vessels of all descriptions, from the smallest fishing-boats to the largest ships that sail on the ocean, present a picture which can scarcely be rivalled on any other spot of the globe. The mildness of the climate has gradually induced the building of large distinct mansions, and has also augmented two towns, which from hamlets have become populous places, deserving here to be noticed. Brixham, or, as it was formerly called, Brixholme, is on the south side of the bay. It is the greatest fishing place in the kingdom, and one of the finest nurseries for seamen. It has a convenient pier, and a complete watering wharf, from which a store of water can be supplied to a fleet with great facility and expedition. The parish church at Brixham is a fine old structure; and at a mile and a half from thence, at the quay, a church has recently been erected, capable of seating 1200 persons. This place has of late been visited by strangers in the summer for sea-bathing, and in the winter for the benefit of enjoying a mild climate. The population of the parish of Brixham amounted in 1821 to 4503, and in 1831 to 5015. Torquay is situated in the cove of Torbay, two miles from the promontory called Hob's-nose. It is sheltered from the waves by a ridge of rocks; and it cannot be exceeded in romantic beauty and picturesque scenery. Here a new pier, projecting southwest from the eastern cliff, affords complete protection to shipping from the southern winds. The regularity of the buildings raised for the accommodation of visitors adds neatness and beauty to the place; and the park, with a new carriage-way to it, and a plantation on one side, is no small embellishment to the place.

Torquay exhibits a remarkable instance of rapid creation, and ranks as one of the most esteemed of the sea-bathing places; possessing all the advantages of the mild climate of the most southern part of the British islands. It is exempted from exposure to the winds from the north and the east by the lofty hill which intervenes. Though there is much bathing company in the summer, yet in the winter, if the visitors are not more numerous, they are more select; as many invalids, or those who feel symptoms of a pulmonary kind, resort to Torquay to pass the severer months, and not only from the neighbouring counties, but from the more northerly parts of England, and even of Scotland. It has every convenience for the purpose of sanatory retirement that the best watering place affords. Provisions are good and cheap; and the rides in the vicinity, though rather hilly, are kept in good condition. This place is in two parishes. One of these is Tor-Mohain, whose population amounted in 1821 to 1925, and 1831 to 3582, and it has rapidly increased since the last of these dates. The other parish is Mary Church, whose inhabitants amounted in 1821 to 1050, and in 1831 to 1204. By calculation in the present year, 1840, Torquay itself is stated to have 6000 residents, exclusively of those strangers that resort to it in the two seasons between which the parliamentary enumerations have been taken. The objects in the vicinity that engage the attention of visitors are, Tor Abbey, an ancient edifice; Poole's Hole, a very curious cavern; Kent's Hole, one much larger, with three entrances, and a roof thirty feet high. There are several fine seats in the neighbourhood.

TOREE, a town of Hindustan, in the province of Bahar, 125 miles south from Patna. Long. 85. 2. E. Lat. 23. 42. N.

TORGAU, a city of Prussian Saxony, in the government of Merseburg, the capital of a circle of the same name, which extends over 344 square miles, and contains 36,500 inhabitants. The city stands on the river Elbe, and being strongly fortified, is in war a most important post. It is defended by two strong fortresses, and contains a lyceum, 720 houses, and 6400 inhabitants, who carry on some manufactures of cloth and linen, and much trade on the river in corn, timber, salt, and other articles.

TORIES, a political party in Britain, opposed to that of the Whigs. The name of *Tories* was given to a sort of banditti in Ireland, and was thence transferred to the adherents of Charles I. by his enemies, under the pretence that he favoured the rebels in Ireland. His partisans, to be even with the republicans, gave them the name of *Whigs*, from a word which signifies *whey*, in derision of their poor fare. The Tories, or *cavaliers*, as they were also called, had then principally in view the political interest of the king, and the church of England; and the round-heads, or Whigs, proposed chiefly the maintaining of the rights and interests of the people, and of Protestantism. This is the most popular account; and yet t is certain the names *Whig* and *Tory* were but little known till about the middle of the reign of King Charles I. M. de Cize relates, that it was in the year 1678 that he whole nation was first observed to be divided into Whigs and Tories; and that on occasion of the famous deposition of Titus Oates, who accused the Catholics of having conspired against the king and the state, the appellation of *Whig* was given to such as believed the plot real, and *Tory* to those who held it fictitious. It would, at the present day, be very difficult, if not impossible, to assign to these oted terms meanings at once precise and correct, and to which both parties would subscribe. The only general bstract description that can be fairly given would seem to e this, that the Tories hold the power and prerogatives of he crown in most favour, and incline to strengthen and nlarge them; while the Whigs are jealous of and desirous to define and circumscribe both, and proportionally o strengthen and enlarge the liberties and rights of the people.

TORNEA, a town of Sweden, in the most northern spot hat is inhabited. It stands between two rivers, the Torneaelf and the Galixelf; but as the first of these streams forms the boundary between Russian Finland and Sweden, part of the town, which is on the eastern side, now belongs o the Russian empire. There are near it a few mines of ron, but their produce is insignificant, as is the number of he inhabitants. Lat. 67. 51. 9. N. It forms a part of the pastorate of Rannula, whose church is in lat. 68. 50. the most northerly building on the continent of Europe.

Tornea, a place usually denominated a city, in the northern part of Lapland, now a part of the Russian empire. It is the capital of the province of Lapmark, and stands n a peninsula on the sea-shore, with a harbour nearly choked with sand; but being the only port in the Gulf of Bothnia, whatever commerce is there carried on, centres at Tornea. The chief exports are planks, salted salmon, dried fish, rein-deer skins, some tar, and a little butter. The town s composed of about 120 houses, with 750 inhabitants, who mong them are owners of two ships of small burden. Long. 24. 1. E. Lat. 65. 50. 50. N.

TORO, a province in the north-west of the kingdom of Spain, which in ancient times formed the chief part of the kingdom of Leon. It is a large division, extending over 2025 square English miles, and is subdivided into three partidos. The most northern of these partidos is Reynosa, a very mountainous district, with narrow valleys. The other two, Carrion and Toro, have several mountains, but many plains, where, though the ground is rocky and stony, yet there are many spots of rich and fertile soil. The chief production is wheat, the next in quantity rye, which forms the principal food of the inhabitants of the mountains, and after that follow oats, linseed, beans, and a little maize. On the whole, the province raises more corn than t consumes, and some is annually transported to the neighbouring districts. The vineyards are extensive, yielding good wine, and much brandy is distilled from the grapes. The stock of cattle consists of 260,000 sheep, 10,800 black cattle, 3100 horses, 3900 mules, 4700 asses, 11,900 goats, and 15,200 swine; and its bees yield 3400 pounds of wax, and a proportionate but unascertained quantity of honey. According to Arguelles, the population was 97,370 persons, in 19,474 families. The number of houses inhabited was 17,875, and of those in ruins 2413. Two of the principal rivers of the peninsula, the Ebro and the Duero, water this province. The cities are Toro, Carrion, and Reynosa, the towns 82, the villages 239, the hamlets 391.

Toro, a city of Spain, the capital of the province of the same name, stands on the most fruitful of the plains, on the river Duero, over which is a bridge. It is not ill built, and the streets, though filthy, are not narrow. Toro is surrounded with old and dilapidated walls. It contains twenty-two parish churches, fourteen monasteries, four hospitals, 1600 houses, and 7500 inhabitants, who subsist chiefly by the little rent which they draw from the soil that surrounds them. It has nothing approaching to trade, except the domestic making of linen by each family for its own use.

TOROFF, a town of Hindustan, in the province of Bengal, seventy-seven miles north-east from Dacca. Long. 91. 18. E. Lat. 24. 20. N.

TORONTAL, a palatinate of the Austrian kingdom of Hungary, one of the three divisions which compose the Bannat of Temeswar. It extends over a plain, and is 2700 square miles in compass. Two thirds consist of arable land, and the rest of pasture, vineyards, and woods. It is watered by the Theiss, the Maros, and the Aranka, and their tributary streams. It is a district highly productive of corn, and is cultivated by colonists, who are mostly Germans or Bulgarians, with considerable skill and activity. The population consists of 214,500 persons. The chief town is Micklos, on the river Aranka.

TOROPEZ, a city of Russia, in the stadtholderate of Pfkow and in the province of Moscow, the capital of a circle of the same name. It stands on the river Toropa, and is 370 miles distant from St Petersburg. It is a place of considerable industry. Here are many tanneries; and large quantities of linen are made from the excellent flax and hemp produced in the neighbourhood. Toropez is favourably situated for water communication by the Duna with Riga. It contains thirteen churches, two monasteries, 1250 houses, and 13,500 inhabitants. Long. 31. 41. E. Lat. 56. 29. 30. N.

TORRE del Greco, a city of Italy, in the province of Naples. It stands on the sea-shore, at the foot of Mount Vesuvius, by whose irruptions it suffered very considerably in the years 1637, 1794, and 1801. The second of these irruptions nearly destroyed the whole of the houses and public buildings. The depth of the lava was in some places twenty-five feet, so that the entrance to several houses is now in the second story. These events have not prevented the people from continuing to make it their residence; and it now contains upwards of 15,000 inhabitants, who are employed chiefly in the tunny, anchovy, and oyster fisheries. There is also a coral manufactory, and some good wine is made from the vineyards.

TORREFACTION, in *Chemistry*, is the roasting or scorching of a body by the fire, in order to discharge a part either unnecessary or hurtful in another operation. Sulphur is thus discharged from an ore before it can be wrought to advantage.

TORRENT denotes a temporary stream of water falling suddenly from mountains, where there have been great rains or an extraordinary melting of snow.

TORRESVEDRAS, a town of Portugal, the capital of a corregimiento of the province of Estremadura. It is one of the most ancient places of the kingdom, and is situated on a rising ground, at the foot of which is a small pellucid stream, called the Sisera. The town contains four churches, the same number of convents and hospitals, and a population of about 2500 persons, who are supplied with water from a small but beautiful marble aqueduct. Good wnie is made in the vicinity. It has been deemed a place of great importance in all the wars which from remote ages have visited Portugal, but was peculiarly distinguished when the duke of Wellington held the command of the allied armies. This place is about twenty-eight miles from Lisbon, on the road to Coimbra. From it there is an extensive chain of points, some formed by nature, and others by art, stretching from the town to the river Tagus, behind which the duke collected an army to await the enemy, who, with a force of vastly superior numbers, had driven him out of Spain.

TORRICELLI, Evangelista, an illustrious Italian mathematician and philosopher, was born on the 15th of October 1608. It seems doubtful whether he was born at Modigliana, a country-seat in Romagna, or at Piancaldoli, in the diocese of Imola. He was trained in Latin literature by his uncle, a monk of Faenza; and after cultivating mathematical knowledge for some time without a master, he studied under Father Benedict Castelli, professor of mathematics at Rome. Having read Galileo's dialogues, he composed a treatise on motion, on his principles. This recommended him to the notice of Galileo, who took him home as an assistant; but Galileo died in three months after. He became professor of mathematics at Florence, and greatly improved the art of making telescopes and microscopes. But he is best known for discovering a method of ascertaining the weight of the atmosphere by quicksilver; the barometer being called, from him, the Torricellian tube. He published a volume entitled "Opera Geometrica." Florent. 1644, 4to. He died in the year 1647.

TORRINGTON, Great, a town in the hundred of Fremington and county of Devon, 197 miles from London. It is situated on the side of a hill, in a bleak district, was once a borough, and had a castle, the ruins of which are still visible. There is a market on Saturday. The inhabitants amounted in 1821 to 2538, and in 1831 to 3093.

TORSHOK, a city of European Russia, in the province of Moscow and government of Twer. It is the capital of a circle of the same name, which comprehends forty-eight parishes, in which are 483 villages, with 78,800 inhabitants. The city is 334 miles from St Petersburg, stands on the river Twerza, and contains twenty-three churches, a large bazaar, and 1850 houses, with 16,400 inhabitants, who are distinguished by the excellence of the leather which they fabricate, and by their taste in embroidery of boots and slippers with gold and silver thread from the markets of Turkey. They have also much trade in hemp and flax. Long. 34. 58. 10. E. Lat. 57. 2. 9. N.

TORTOLA, the principal of the Virgin Islands, is situated in long. 64° 39′ west, and lat. 18° 20′ north. It is about twelve miles long from east to west, and on an average four miles wide. It consists of one mountain mass, running along the middle of the island in abrupt and irregular forms, which, on the west side of the island, rise above 1500 feet. The shores are indented with bays, harbours, and creeks, affording shelter and anchorage to a great extent of shipping. A great part of the interior consists of large tracts of waste land. Along the shore are a few tracts of flat ground, but the soil is thin and impoverished. The population amounted in 1835 to 7731. In 1836 the value of the exports was L.23,129, of which L.21,213 was for sugar and molasses. The imports were L.15,225, consisting chiefly of corn and British manufactures.

TORTOISE-SHELL, the scales of the testaceous animal called a *tortoise*, used in inlaying, and in various other works. See Reptilia, genus *Testudo*.

TORTONA, a city of Italy, in the kingdom of Sardinia and province of Turin, the capital of a district of the same name. It stands at the foot of the Apennines, on the river Scrivia. It is strongly fortified, and is defended by a citadel. It contains a cathedral, four parish churches, eleven monasteries, and three nunneries, with 8480 inhabitants, who make silk goods, hosiery, hats, and leather, and trade with Genoa in corn, wine, and rice. Long. 8. 39. E. Lat. 44. 56. N.

TORTOSA, a city of Spain, which gives its name to the department on the south-west corner of the province of Catalonia. It stands on the bank of the river Ebro, about six leagues from its mouth. On that stream there is not any upward navigation, owing to the falls of water at Xerta, above the town. At Tortosa there is a passage across the river by a bridge of boats. It is strongly fortified, and is defended by Fort St Blas, in the suburb, and by a strong citadel on a rocky height near it. The buildings are in the antique style, and the streets very irregular. It is the seat of a bishop, and has a fine cathedral, and three parish and ten conventual churches, together with an ecclesiastical seminary. The inhabitants are about 16,700. The adjacent district yields abundance of the finest marbles and alabaster. One of the chief articles of its commerce is the liquorice, which grows abundantly, and almost spontaneously. It requires 400 pounds weight of the root to make fifty pounds of the juice for the shops. When attention is paid to the cultivation, the produce is very great; and the operation of digging it up prepares the ground for a crop of wheat better than the practice of fallowing. There are in the city several distilleries of brandy, some manufactories of porcelain, and some of paper. There are also many persons occupied in the fisheries. Ships do not approach very near Tortosa, but discharge or take in their cargoes at the village Amposta, where there is a canal which communicates with Rapita and the port of Alfaques, beyond the bar of the Ebro. There that river discharges itself into the sea by two mouths formed by the island of Buda, the eastern point of which is in long. 0. 55. E. and lat. 40. 43. 55. N.

TORTURA, a small seaport of Palestine. In the times of Christianity it was erected into a bishopric, but has now dwindled into an inconsiderable village. It is fifteen miles south of Acre.

TORTURE, a violent pain inflicted on persons to force them to confess the crimes laid to their charge, or as a punishment for crimes committed.

TOSANLU, a river of Asia Minor, the ancient Lycus, which rises in the mountains of Armenia, and after a course westward of about 200 miles, falls into the Jekil Irmak, about thirty miles north of Amasia.

TOSSIA, a town of Asia Minor, situated on the Kisil Irmak, and on the route from Amasia to Constantinople, in a fine valley, producing a considerable quantity of rice. Long. 34. 10. E. Lat. 40. 20. N.

TOTNES, a town of the hundred of Coleridge, in the county of Devon, 195 miles from London. It stands on the side and the top of a steep hill, at whose foot the river Dart flows. It is about twelve miles from the sea, but the tide flows up to the bridge, by which the river is connected with the suburb. It is a place of little trade. The church is a spacious building, with a lofty tower. Totnes was once fortified, and was defended by a castle, the remains of which are still visible. It is a corporate town, governed by a mayor and eleven councillors, and returns two members to the House of Commons. There is a market on Saturday, which is well supplied with every kind of provisions at cheap rates. The inhabitants amounted in 1821 to 3128, and in 1831 to 3442.

TOTTENHAM, a large parish of the hundred of Edmonton, in the county of Middlesex, five miles from London. It is on the great north road by Ware. It is chiefly the residence of persons connected with the metropolis, and is a very pleasant retreat from the bustle of the city. It is divided into four wards, denominated Middle, Nether, High Cross, and Wood Green. The inhabitants amounted in 1821 to 5722, and in 1831 to 6937.

TOUCH-NEEDLE, among assayers, refiners, &c., little bars of gold, silver, and copper, combined together, in all the different proportions and degrees of mixture; the use of which is to discover the degree of purity of any piece of gold or silver, by comparing the mark which it leaves on the touchstone with those of the bars. The metals usually tried by the touchstone are gold, silver, and copper, either pure, or mixed by fusion with one another, in different degrees and proportions. In order to discover the purity or quantity of baser metal in these various admixtures, when they are to be examined they are compared with these needles, which are mixed in a known proportion, and prepared for this use. The metals of the needles, both pure and mixed, are all made into laminæ or plates, one twelfth of an inch broad, and of a fourth part of their breadth in thickness, and an inch and a half long. These being thus prepared, a mark is to be engraved on each, indicating its purity, or the nature and quantity of the admixture. The black rough marbles, the basaltes, or the softer kinds of black pebbles, are the most proper for touchstones.

The method of using the needles and stone is this. The piece of metal to be tried ought first to be wiped well with a clean towel or piece of soft leather, that you may the better see its true colour; for from this alone an experienced person will in some degree judge beforehand what the principal metal is, and how and with what debased. Then choose a convenient, not over large, part of the surface of the metal, and rub it several times very hardly and strongly against the touchstone, that in case a deceitful coat or crust should have been superinduced, it may be worn off by that friction. This however is more readily done by a grindstone or small file. Then wipe a flat and very clear part of the touchstone, and rub against it, over and over, the just-mentioned part of the surface of the piece of metal, till you have, on the flat surface of the stone, a thin metallic crust, an inch long, and about an eighth of an inch broad. This done, look out the needle that seems most like to the metal under trial; wipe the lower part of this needle very clean, and then rub it against the touchstone, as you did the metal, by the side of the other line, and in a direction parallel to it. When this is done, if you find no difference between the colours of the two marks made by your needle and the metal under trial, you may with great probability pronounce that metal and your needle to be of the same alloy, which is immediately known by the mark engraved on your needle. But if you find a difference between the colour of the mark given by the metal and that by the needle you have tried, choose out another needle, either of a darker or lighter colour than the former, as the difference of the tinge on the touchstone directs; and by one or more trials of this kind you will be able to determine which of your needles the metal answers, and thence what alloy it is of, by the mark of the needle; or else you will find that the alloy is extraordinary, and not to be determined by the comparison of your needles.

TOUCHSTONE, a black, smooth, glossy stone, used to examine the purity of metals. The ancients called it *lapis Lydius*, the Lydian stone, from the name of the country whence it was originally brought. Any piece of pebble or black flint will answer the purposes of the best *lapis Lydius*. Even a piece of glass made rough with emery is used with success to distinguish true gold from such as is counterfeit, both by the metallic colour and the test of aquafortis. The true touchstone is of a black colour, and is not uncommon in many parts of the world.

TOUL, an arrondissement of the department of the Meurthe, in France, extending over 463 square miles. It is divided into five cantons, and these into 119 communes; and in 1836 it contained 64,041 inhabitants. The chief city, of the same name, stands on a plain at the foot of hills covered with vines, and watered by the river Moselle. It is the seat of a bishop, has a fine Gothic cathedral and other three churches, a hospital, an arsenal, and some well-built barracks. It contained in the same year 7333 inhabitants, whose chief trade is in wine and brandy. Long. 5. 48. 13. E. Lat. 48. 40. 32. N.

TOULON, an arrondissement of the department of the Var, in France, extending over 504 square miles. It comprehends seven cantons, divided into 128 communes, having 99,012 inhabitants in 1836. The capital, of the same name, is one of the most complete naval arsenals belonging to France in the Mediterranean Sea. It has two good havens, one for the merchants and the other for the navy, with every convenience for the building and equipment of the largest ships. The entrance is good, and the port secure at all times. The entrance is protected by strong batteries, while several fortresses on the hills which surround the city completely command every part of it, as well as the arsenals and harbours. These were found so effectual, that when one of them, the fortress of Malgua, was taken by the French, the British, who were in possession of the harbours, the city, and the arsenals, were under the necessity of abandoning them with the utmost expedition. The place is divided into the old and the new town. It has a fine square, a beautiful town-hall, a Gothic cathedral with a magnificent portico, a theatre, and a palace for the intendant. The plain on which the city stands is fertile, and the hills that surround it are covered with vines, figs, capers, and olive trees, and yield abundance of fruits. The trade, which is not very great, arises from some manufactories of silk, woollen goods, and soap. Toulon has also some fisheries. In the year 1836 it contained 35,322 inhabitants. Long. 5. 50. 21. E. Lat. 43. 7. 16. N.

Toulouse.

TOULOUSE, an arrondissement of the department of Upper Garonne, in France. It extends over 619 square miles, and is subdivided into twelve cantons and 135 communes, with a population in 1836 amounting to 159,064.

Toulouse, a city of France, the ancient city of *Tolosa*, latterly the capital of the old province of Languedoc, and now the chief town both of the arrondissement of the same name, and of the department of Upper Garonne. It is situated in a fertile district on the banks of the river Garonne, which divides it into two equal parts, connected by a magnificent bridge, after the plan of Mansard, of seven arches, 810 feet in length and seventy-two in breadth, on which is a triumphal arch. The city is surrounded by walls, which yield an agreeable promenade to the inhabitants, and, with the broad quays which extend along the banks of the river, give to it an imposing appearance. When under the sway of the Romans, and forming one of the principal settlements of the empire, this city was adorned by numerous monuments; but in the course of ages these have been destroyed, and nothing now attests its former state but the remains of a small amphitheatre, and a single tomb in the cloister of the old church of the Augustines. In 1816 most of the buildings were more or less injured by an explosion of a powder magazine. The streets are narrow and crooked; brick buildings are too numerous; and the squares, with the exception of St Cyprian, are deficient in regularity; yet some of the edifices are to be admired, more particularly that of the Hotel de Ville, called the *Capitole*, whose modern front is considered one of the finest in France. The principal institutions in the city are a well-frequented university, a school of medicine and surgery, a botanic garden and observatory, a public library, a school of artillery, an academy of fine arts with a collection of paintings, various charitable institutions and religious edifices, which, with the exception of one Protestant place of worship, belong to the Catholics. This city is the head-quarters of a military division, the seat of the prefect, and of the courts of law for the department. There is less trade than the situation of the city and the population would lead a stranger to expect. It is chiefly confined to the agricultural produce of the neighbourhood, and the manufacture, upon a small scale, of powder, snuff, brandy, starch, leather, pottery ware, cotton, silk, and woollen goods. There is also a royal cannon foundery, and yards for building vessels. In the vicinity there are many country houses and gardens, belonging to the wealthier citizens; and this circumstance gives Toulouse an air of cheerfulness and prosperity much more resembling an English than a French town. The population in 1836 amounted to 77,372. Long. 1. 21. 16. E. Lat. 43. 35. 36. N.

TOURNAGHAUT, a celebrated pass of the south of India, leading from the western coast, called the Concan, into the interior of that country. It is more rugged and steep than that of Ambah. Long. 72. 25. E. Lat. 17. 47. N.

TOURNAMENT, a martial sport or exercise which the ancient cavaliers used to perform, to show their bravery and address. It is derived from the French word *tourner*, i. e. "to turn round," because, to be expert in these exercises, much agility both of horse and man was requisite. The first tournaments were only courses on horseback, in which the cavaliers tilted at each other with canes in the manner of lances; and were distinguished from justs, which were courses or careers, accompanied with attacks and combats with blunted lances and swords. The prince who published the tournament, used to send a king at arms, with a safe-conduct and a sword, to all the princes, knights, &c. signifying that he intended a tournament and clashing of swords, in the presence of ladies and damsels; which was the usual formula of invitation. They first engaged man against man, and then troop against troop. After the combat, the judges allotted the prize to the best cavalier, and the best striker of swords; and he was accordingly conducted with pomp to the lady of the tournament, where, after thanking her very reverently, he saluted her, and likewise her two attendants.

These tournaments formed the principal diversion of the thirteenth and fourteenth centuries. Munster says, it was Henry the Fowler, duke of Savoy, and afterwards emperor, who died in 936, that first introduced them; but it appears from the Chronicle of Tours, that the true inventor of this famous exhibition, at least in France, was one Geoffrey, lord of Preuilli, about the year 1066. Instances of them occur among the English in the reign of King Stephen, about the year 1140; but they were not much in use till Richard's time, towards the year 1149. After this period these diversions were performed with extraordinary magnificence, in the Tiltyard near St James's, Smithfield, and other places.

The following is the account of a tournament, from Maitland. King Richard II. designing to hold a tournament at London on the Sunday after Michaelmas, sent divers heralds to make proclamation of it in all the principal courts of Europe; and accordingly not a few princes, and great numbers of the prime nobility, resorted hither from France, Germany, the Netherlands, &c. This solemnity began on Sunday afternoon, from the Tower of London, with a pompous cavalcade of sixty ladies, each leading an armed knight by a silver chain, being attended by their squires of honour; and, passing through Cheapside, they rode to Smithfield, where the justs and tournaments continued several days with a magnificent variety of entertainments; on which occasion the king kept open house at the bishop of London's palace for all persons of distinction, and every night concluded with a ball.

At last, however, tournaments were found to be productive of bad effects, and the occasions of several fatal misfortunes; as in the instance of Henry II. of France, and of the tilt exhibited at Chalons, which, from the numbers killed on both sides, was called the *little war of Chalons*. These and other inconveniences, resulting from such dangerous pastimes, gave the popes occasion to forbid them, and the princes of Europe gradually concurred in discouraging and suppressing them.

TOURNAY, an arrondissement of the province of Hennegau, in the Netherlands, comprehending eleven cantons, divided into 142 communes, containing 198,900 inhabitants. The capital is the city of the same name. It is the seat of a bishop, who has a fine cathedral with four towers; and under his direction there is an ecclesiastical seminary, as well as several churches. Tournay is situated on the river Scheldt, by which it is divided into two parts. It is surrounded with walls, and has extensive suburbs. It is for the most part well built, contains 2800 houses, and 25,100 inhabitants. It is a place of great celebrity for its manufactures, for some of which there are very large establishments. One of the most extensive is that for making carpets; and others for printing calicoes rival it. Almost every kind of cotton goods is made, and each step of the process, from spinning in mills to the bleaching and finishing, is performed. Besides piece-goods, there are some manufactures of porcelain and of bronze articles. In the vicinity excellent stone abounds. Long. 3. 56. 58. E. Lat. 50. 36. 20. N.

TOURNEFORT, Joseph Pitton de, a famous botanist, was born at Aix in Provence on the 5th of June 1656. He studied in the College of the Jesuits at Aix, and his father destined him for the church. He accordingly commenced his theological studies; but he felt a very early passion for the study of botany, and the death of his father in 1677 left him more at liberty to gratify his own inclinations. He wandered over the mountains of Dauphiny, Savoy, Catalonia, the Pyrenees, and the Alps, in search of new species of plants, which he collected with much fatigue and danger. In 1679 he repaired to Montpellier, where he continued for two years to prosecute the study of medicine. He made a botanical excursion to Spain in 1681, and afterwards returned to the university. Having taken the degree of M. D. at Orange, he returned to his native city, where however he did not long remain. In 1683, his reputation procured him the appointment of professor of botany in the king's garden; and by the king's order he travelled into Spain, Portugal, Holland, and England, where he made prodigious collections of plants. In 1698 he was received as M. D. in the university of Paris. In obedience to another order, he proceeded in 1700 to the isles of the Archipelago, the coasts of the Black Sea, Bithynia, Pontus, Cappadocia, Armenia, and Georgia; making observations on natural history at large, ancient and modern geography, religion, manners, and commerce. In this learned voyage he spent three years, and then resuming his profession, was made professor of physic in the Royal College. He died in consequence of an accidental bruise of his breast by a cart-wheel, which brought on a spitting of blood and hydrothorax, that proved fatal on the 28th of November 1708.

Tournefort produced various works, of which we shall only enumerate the most considerable. "Elémens de Botanique, ou Méthode pour connaitre les Plantes." Paris, 1694, 3 tom. 8vo. This work he enlarged, and published in Latin, under the title of "Institutiones Rei Herbariæ, sive Elementa Botanices." Paris. 1700, 3 tom. 4to. "Histoire des Plantes qui naissent aux environs de Paris, avec leur Usage dans la Médecine." Paris, 1698, 12mo. In 1725, an edition of this work was published by Bernard de Jussieu in 2 vols. 12mo; and in 1732 an English translation by Martyn in 2 vols. 8vo. "Relation d'un Voyage du Levant, contenant l'Histoire ancienne et moderne de plusieurs Isles d'Archipel, de Constantinople," &c. Paris, 1717, 2 tom. 4to. Bernier was the editor of his posthumous "Traité de la Matière Medicale; et l'Histoire et l'Usage des Médicaments, et leur Analyse chimique." Paris, 1717, 2 tom. 12mo.

TOURNIQUET, in *Surgery*, an instrument formed with screws, for compressing any part with rollers, &c. for the purpose of stopping hæmorrhages.

TOURNON, an arrondissement of the department of the Ardèche, in France, extending over 719 square miles. It comprehends eleven cantons and 124 communes, with 134,569 inhabitants in 1836. The capital is the city of the same name, situated on the side of a hill rising from the ight bank of the Rhone, where the Doux falls into that iver. In 1836 it contained 4174 inhabitants, employed in making woollen, and trading in silk obtained near them. Long. 4. 40. E. Lat. 45. 6. N.

TOURNUS, a city of France, in the department of the aone and Loire, and arrondissement of Maçon. It is finely tuated on a rising ground on the banks of the Saone, over hich is a new bridge of fifteen arches. In 1836 it had a opulation of 5314 persons, who carry on considerable trade n wine, corn, and wood.

TOURS, a city of France, in the department of the In- e and Loire, of which, as well as of the arrondissement f its own name, it is the capital. The arrondissement is 037 square miles in extent, and comprehends ten cantons nd 127 communes, with 151,119 inhabitants in 1836. The ty stands on a well-cultivated plain on the left bank of the oire, over which is a stone bridge 1340 feet in length. ours is a place of great antiquity, and is connected with any historical recollections. It is surrounded with ancient alls, which now form a promenade, encompassed by beau- ful gardens, converted from what were at one time the tches. The high street leading from the bridge is a pic- resque mass of buildings. The cathedral is a fine Gothic uilding, with a beautiful portico surmounted by two towers. he palace of the archbishop is also a remarkable building. here are in all fifteen churches. It was before the revo- tion one of the chief seats of the silk manufacture, and ly second to Lyon; but that has given place in some mea- re to the making of woollen goods. There are several tan- ries, and also distilleries for making brandy. The coun- y around is of great fertility, provisions are abundant and eap, and the wine good. In 1836 the population amount- to 26,669 persons. Long. 0. 36. 27. E. Lat. 47. 23. . N.

TOWCESTER, a town in the hundred of the same me, in the county of Northampton, sixty miles from Lon- n. It stands on the banks of the river Weedon, and was merly a place of great repute. It has now only a little ade in making lace, and what arises from its being on the eat north-west road. There is a well-supplied market on uesday. In 1821 the inhabitants amounted to 2554, and 1831 to 2671.

TOWNSHEND Island, on the east coast of New Hol- nd, which Captain Cook thought to belong to the mainland; t it was ascertained to be an island by Captain Flinders. ong. of the cape, 159. 29. E. Lat. 22. 13. S.

TOWYN, a town of North Wales, in the county of Me- neth, on a river of the same name, 217 miles from Lon- n and eleven from Barmouth. The country around it very fertile, and the parish is very extensive. The annual ue of the landed property in it was estimated, under the essment of 1815 to the property-tax, at L.10,570. The lage, though built of coarse stone, is respectable, and of e years has been much frequented by sea-bathers. In the urch-yard is a huge pillar, supposed to have been erect- to a Saint Cadavan. In 1821 the population amounted 2369, and in 1831 to 2694.

TRADITION, something handed down from one gene- ion to another without being written. Thus the Jews tended, that besides their written law contained in the d Testament, Moses had delivered an oral law, which had en conveyed down from father to son; and thus the Ro- n Catholics are said to value particular doctrines sup- sed to have descended from the apostolic times by tradi- n.

TRAFALGAR, a cape on the coast of Spain, just with- t the Straits of Gibraltar, and opposite to Cape Esparte the African shore. It was called by the ancients the omontory of Juno. It is in latitude 36° 10′ 15″ north, and gitude 6° 1′ 30″ west. It is not high, but may be known by its remarkable figure, being flat, and terminating with two sharp corners or angles, near to which is a round tower. To the eastward of this flat the land is very uneven, and indeed mountainous. This spot is remarkable from the great naval victory achieved near it on the 21st October 1805.

TRAGEDY, a dramatic poem, representing some signal action performed by illustrious persons, which has frequently a fatal issue or termination. See Drama and Poetry.

TRAGI-COMEDY, a dramatic piece, partaking both of the nature of tragedy and comedy; in which a mixture of merry and serious events is admitted.

TRAITOR'S Island, in the Pacific Ocean, discovered by Le Mair and Schouten in 1616. Long. 173. 48. W. Lat. 15. 55. N. There is also a cluster of islands of the same name on the coast of New Guinea. Long. 137. E. Lat. 1. 12. S.

TRALEE, a borough and the chief town of the county of Kerry, distant from Dublin, by way of Limerick and Castle Island, 144 miles. It is situated upon the river Lee, which here falls into Tralee Bay, after passing through the flat and fertile tract of land which stretches along its shore. The town consists of two streets upwards of a mile in length, broken by a square in the centre, from which diverge several regular and well-planned cross streets. Many of the houses are well built, and inhabited by a respectable class of individuals; but there are many inferior houses and mud-huts interspersed throughout, and extending along the suburbs. It has several public buildings, namely, the court-house, county prison, infirmary, a handsome modern church, two Roman Catholic chapels, and several dissenting meeting-houses, and a barrack capable of containing 600 men. Tralee has of late years been very considerably improved, and the export and import trade has greatly increased. The number of vessels which entered its creek in 1838 amounted to eighty-four, having a tonnage of 6092, and cargoes valued at L.60,920. Those that cleared outwards in the same year amounted to 119, with a tonnage of 9512, and cargoes valued at L.95,120. The town is connected with the sea by means of a ship-canal recently opened; but as yet the principal shipping load and discharge their cargoes at Blennerville, about one mile and a quarter below the town. Tralee is governed by a provost and twelve free burgesses, who, with the qualified inhabitants, return a member to parliament. The population in 1831 amounted to 9568.

TRALLIANUS, Alexander, or Alexander of Tralles, a medical writer, was a native of Tralles, a city of Lydia, and lived about the middle of the sixth century. He is the author of a work, divided into twelve books, in which he treats of distempers as they occur from head to foot. He was the first that opened the jugular vein, and that used cantharides as a blister for the gout. Though he appears on the whole to have been a rational physician, yet there are passages in his writings that savour of enthusiasm and superstition. Dr Freind, in his History of Physick, styles him one of the most valuable authors since the time of Hippocrates. See likewise Dr Milward's "Trallianus Reviviscens; or, an Account of Alexander Trallian, one of the Greek writers that flourished after Galen; being a supplement to Dr Freind's History of Physick." Lond. 1734, 8vo. The Greek text of his principal work was first published by Jac. Goupylus, Lutet. 1548, fol. It was reprinted, and was then accompanied with a Latin version by Jo. Guinterius, Basil. 1556, 8vo. He is likewise the author of an epistle on worms, "De Lumbricis;" which was published, in Greek and Latin, by Mercurialis in his "Variæ Lectiones," Venet. 1570, 4to.

TRAMORE, a small, straggling, but handsome town, in the county of Waterford, eighty-three miles from Dublin. It is situated at the western extremity of the bay of the same name, and contains many excellent private houses and villas. It is much frequented during the bathing season by the inhabitants of Waterford and the adjoining country. The population in 1831 was 2224.

TRANENT, a market-town in the county of Haddington, nine miles and a half from Edinburgh. It consists of one long street, through which the principal road to Berwick passes, and several minor by-streets, to none of which can be given the praise of being either handsome or clean. The houses are chiefly inhabited by colliers, who are employed in the extensive mines which have been worked here for several centuries. There is a weekly market for grain. The population of the town and parish in 1831 amounted to 3620.

TRANI, a city of Italy, in the Neapolitan province of Bari, the capital of the district of the ancient Puglia. It stands on the sea-shore, is walled, and is defended by a castle. It is the seat of an archbishop, with a fine Gothic cathedral, said to have been erected by the Normans. It is well built of excellent stone, has a spacious market-place, several churches, ten monasteries, and 13,780 inhabitants. The harbour is shallow, and only visited by coasting vessels. The wine and figs produced in the neighbourhood are good, and form the chief trade.

TRANQUEBAR, a small seaport of the south of India, in the province of the Carnatic and district of Tanjore, situated at one of the mouths of the Cavery river. It was formerly a village belonging to the rajah of Tanjore, from whom it was purchased by the Danes in 1616. Here they erected the fort of Dansborg, to which population and commerce were soon attracted by the protection derived from the Danish flag, and by the correct conduct of the company's servants. The company however did not prosper; and in 1624 they surrendered their charter and property to the king of Denmark, in payment of a debt owing to him. The revenues however continued, under frugal management, to defray all the expenses; and while Denmark remained neutral, the merchants here profited greatly by lending their names during the war to cover British property. In 1807, when the war commenced with Great Britain, the Danes were deprived of this with all their other settlements, which were however restored to them on the conclusion of a general peace.

TRANSCENDENTAL, or Transcendent, something elevated, or raised above other things; which passes and transcends their nature.

TRANSFUSION of Blood, an operation by which it has been imagined that the age of animals may be renewed. The method of transfusing Dr Lower gives us to the following effect. Take up the carotid artery of the dog, or other animal, whose blood is to be transfused into another of the same, or a different kind: separate it from the nerve of the eighth pair, and lay it bare above an inch. Make a strong ligature on the upper part of the artery; and an inch nearer the heart another ligature with a running knot, to be loosened and fastened as occasion requires. Draw two threads between the two ligatures, open the artery, put in a quill, and tie up the artery again upon the quill by the two threads, and stop the quill by a stick. Then make bare the jugular vein of the other animal for about an inch and a half in length, and at each end make a ligature with a running knot; and in the space between the two knots draw under the veins two threads, as in the other. Open the vein, and put into it two quills, one into the descending part of the vein, to receive the blood from the other dog, and carry it to the heart; the other quill put into the other part of the jugular, towards the head, through which the second animal's own blood is to run into dishes. The quills being tied fast, stop them up with sticks till there be occasion to open them. Things being thus disposed, fasten the dogs on their sides towards one another, in such a manner as that the quills may go into each other; then unstop the quill that goes down into the second dog's jugular vein, as also that coming out of the other dog's artery; and by the help of two or three other quills put into each other, as there shall be occasion, insert them into one another. Then slip the running knots, and immediately the blood runs through the quills as through an artery, very impetuously. As the blood runs into the dog, unstop the quill in the upper part of his jugular, for his own blood to run out at, though not constantly, but as you perceive him able to bear it, till the other dog begins to cry and faint, and at last die. Lastly, take both quills out of the jugular, tie the running knot fast, and cut the vein asunder, and sew up the skin: the dog, thus dismissed, will run away as if nothing ailed him.

In the Philosophical Transactions we have accounts of the success of various transfusions practised at London, Paris, in Italy, &c. Sir Edmund King transfused forty-nine ounces of blood out of a calf into a sheep; the sheep, after the operation, appearing as well and as strong as before. M. Denis transfused the blood of three calves into three dogs, which all continued brisk, and ate as well as before. The same person transfused the blood of four wethers into a horse twenty-six years old, which thence received much strength, and a more than ordinary appetite. Soon after this operation was introduced at Paris, viz. in 1667 and 1668, M. Denis performed it on five human subjects, two of whom recovered of disorders under which they laboured; one being in perfect health suffered no inconvenience from it; and two persons who were ill, and submitted to the operation, died; in consequence of which the magistrates issued an order, prohibiting the transfusion on human bodies, under pain of imprisonment. Mr John Hunter, we are told, made many ingenious experiments to determine the effects of transfusing blood, some of which are sufficient to attract attention. But whether such experiments can ever be made with safety on the human body, is a point not easily determined.

TRANSIENT Notes, or *Passing Notes*. See Music.

TRANSITION, or Modulation, in *Music*. See Music.

TRANSITIVE, in *Grammar*, an epithet applied to such verbs as signify an action which passes from the subject that does it, to or upon another subject which receives it. Under the head of verbs transitive come what we usually call *verbs active and passive;* other verbs, whose action does not pass out of themselves, are called *neuter*.

TRANSLATION, the act of transferring or removing a thing from one place to another; as we say, the translation of a bishop's see, a council, a seat of justice, &c.

Translation is also used for the version of a book or writing out of one language into another. The principles of translation have been clearly and accurately laid down by Dr Campbell of Aberdeen in his invaluable Preliminary Dissertations to his translation of the Gospels. The fundamental rules which he establishes are three: 1. That the translation should give a complete transcript of the ideas of the original; 2. that the style and manner of the original should be preserved in the translation; 3. that the translation should have all the ease of original composition. The rules deducible from these general laws are explained and illustrated with much judgment and taste, in an Essay on the Principles of Translation, by the late Lord Woodhouselee; of which the third edition was published at Edinburgh in the year 1813.

TRANSMIGRATION, the removal or translation of a whole people into another country, by the power of a conqueror.

Transmigration is particularly used for the passage of the soul out of one body into another.

TRANSMUTATION, the act of changing one substance into another.

Transmutation, in alchemy, denotes the act of changing inferior metals into gold or silver. This is also called the *grand operation* effected with the philosopher's stone.

TRANSOMS, in a ship, certain beams or timbers extended across the stern-post of a ship, to fortify her after-part, and give it the figure most suitable to the service for which she is calculated.

TRANSPARENCY, in *Physics*, a quality in certain bodies, by which they give passage to the rays of light: in contradistinction to opacity, or that quality of bodies which renders them impervious to the rays of light.

TRANSPOSITION, in *Grammar*, a disturbing or dislocating the words of a discourse, or a changing their natural order of construction, to please the ear, by rendering the contexture more smooth, easy, and harmonious.

TRANSPOSITION, in *Music*, the removal of a piece of music, either in writing or in performing it, into a key higher or lower than the original one. For the principle of this, see MUSIC, p. 610.

TRANSUBSTANTIATION, in *Theology*, the conversion or change of the substance of the bread and wine in the eucharist, into the body and blood of Jesus Christ; which the Romish church supposes to be wrought by the consecration of the priest.

TRANSVERSE, something that goes across another from corner to corner. Thus bends and bars in heraldry are transverse pieces or bearings; the diagonals of a parallelogram or a square are transverse lines.

TRANSYLVANIA, an extensive province of the Austrian empire, on the eastern side towards the Turkish dominions. In the German language it is called Siebenbürgen, from the seven towers or fortresses by which it was formerly protected against attacks from the Ottoman power. Its Latin name, Transylvania, was derived from its local position beyond the Carpathian Mountains, as part of the ancient Dacia. In the enumeration of the Austrian dominions it is usually denominated a principality. From the 5th century downwards, it was but thinly peopled, and was ruled by various chiefs of tribes. In the year 1004, it was subdued by Stephen the First, king of Hungary, who formed it into an Hungarian province, and divided and governed it by waiwodes or stadtholders. In 1536, the waiwode John Zapolya, after a war with one of his rivals for the dignity, obtained for himself, by a treaty with the emperor Ferdinand the First, the rank and authority of an independent sovereign prince. At this period the Turkish government interfered much in the affairs of the principality, which encouraged the princes of the house of Zapolya, and afterwards the house of Batori, that succeeded. Among the princes of the latter family, Bethlem Gabor and George Rakotzy were mostly distinguished by their animosity to the house of Austria, and the resolute resistance which they made to its authority. At length, in 1689, the emperor Leopold the First completely conquered Siebenbürgen, and concluded, ten years after, a peace at Carlowitz with the Turks, by which the sovereignty of the emperor, in his character of king of Hungary, was guaranteed; but the princely family were secured in their possession of subordinate authority. That house became extinct by the death of Prince Michael Aspasi in 1713, when the sole power fell into the hands of Austria. Maria Theresa raised the district to the more elevated rank of a grand principality in 1765.

This principality extends in latitude from 45° 33′ 55″ to 47° 37′ 3″, and in longitude from 22° 40′ 44″ to 25° 57′ 40″, and comprehends about 24,420 square English miles. It is bounded on the north by Hungary, on the north-east by Buckowina, on the east by Moldavia, on the south by Wallachia, and on the west by Hungary.

It is an elevated district, in which are to be found the sources of the great rivers that run to the Black Sea. The Carpathian range of mountains, in the form of a half-moon, almost encompasses the whole province, sending out spurs from it on both sides, which fill almost the whole surface. The valleys between these spurs vary in extent, but for the most part are highly productive when moderately cultivated. The highest points of the Carpathians within the principality are, the Butshetsch, 8160 feet, the Reticzat, 7800 feet, and the Szurul, 7126 feet, above the level of the Black Sea. The tops of these mountains are commonly clothed with snow till July. Their sides are well covered with woods to the height of about 5000 feet, when the power of vegetation begins to decline, and soon disappears, leaving the summits quite bare and naked. Among these elevations are some most extraordinary natural clefts and grottos, which invite and reward the attention and examination of the traveller.

The inhabitants of this province are of no less than thirteen distinct tribes, according to their origin. The three most distinguished of these classes are called united (*uniti*). They are the Hungarians, the Szecklers, and the Saxons; which last were brought from the parts of Germany then called Saxony, near to Liege, Luxembourg, and Treves, in 1143, by king Seysa the Second. The land is divided among these three nations thus. The Hungarians are in the western division, which extends over one half of the land, and contains rather more than half the population, and is divided into eleven gespanschafts or waiwodeships. The land of the Szeckler is the least; it is thinly peopled, and is subdivided into five bailiwicks. The land of the Saxons is both on the north and the south side of the province, and is the best cultivated as well as the most densely inhabited, and comprises eleven bailiwicks. The remainder of the nation are denominated by their description *Tolerati*, consisting of Wallachians, Greeks, Armenians, Moravians, Poles, Russians, Bulgarians, Servians, Jews, and Gipsies. These last are called Pharohniens, as coming from Egypt, or supposed to have come from thence. Maria Theresa tried to accustom these people to the practices of civilized society; but her efforts, as well as those of her successors, have had but little effect, as they continue averse to agricultural labour, and indeed to any fixed course of life. The Wallachians are the most numerous of these tolerated tribes. The richer part of them have acquired landed estates, but the lower classes are very ignorant, idle, and filthy. The Armenians and the Greeks devote themselves chiefly to traffick. Among all these tribes the Saxons are the most active and orderly. Their villages and dwellings are well built, and everywhere show prosperity and purity of morals. Their written language is the High German, but they speak, or at least have the pronunciation, of the *Platt Deutch*. In the districts inhabited by this race, corn, wine, and culinary vegetables are produced, as well as garden flowers. In the cities of Kronstadt and Hermanstadt, they are the chief conductors of the manufacturing establishments. The religion of the principality is various; and there is a degree of obscurity in the statistical account, which renders any estimate of their relative numbers so very uncertain that only an approximation can be obtained. There are four established (*privilegirte*) religious sects. The Roman Catholics, who amount to about 150,000, have a bishop and other dignitaries, and forty convents. With them are joined what are called the United Greeks, who to a settled point are Catholics; and with them may be classed most of the Armenians. These have also a bishop, several dignitaries, and convents, and the number of them is estimated at 240,000, thus making the whole of the Catholics 390,000. The Reformed or Calvinist Church consists of about 300,000 persons, under a superintendent and two archdeacons, with 587 pastors. The Lutheran Church is calculated to number 250,000 souls; having a superintendent, fourteen deacons, and 286 pastors. The Unitarians or Socinians are mostly refugees from Poland, who were received into this province when persecuted in their native country, where they were joined by

Transylvania.

some of the Szecklers, and a few others. Their numbers are said not to exceed 40,000 persons; but they have a bishop, 110 churches and fifty-four chapels. Each of these sects has its established institutions for education. Thus the Catholics have a college at Clausenburg, and lyceums or grammar schools at Karlsburg, Maros, Basarhely, Udvarhely, and Hermanstadt; the Protestants have colleges at Nagy-Enyed, Maros, Clausenburg, Vasarhely, and Broos; the Lutherans have colleges in Hermanstadt, in Mediaset, Schasburg, and Bisztritz; and the Unitarians have a college at Clausburg, and gymnasiums at Thorenburg and at Hermanstadt. Besides these established religious sects, there is one whose adherents are more numerous than all the others together, which is tolerated, but not privileged. These are the Greeks who believe the doctrines of the pure church of their name, under the patriarch of Constantinople. They consist of Wallachians, Bulgarians, Greeks, and the Gypsies. They have an archbishop, twenty-nine archdeacons, and 991 churches, but no institutions for education. They consist of the lowest class of labourers both in agriculture and in mining.

The greatest export of agricultural produce is that of tobacco, of which much is grown of a quality highly admired. The breeding of horses is an extensive pursuit, in which the Gypsies are said to be very skilful. The breed most common is of slight make, but very agile, strong, and capable of enduring labour. Most of the gentry support establishments to improve the breed of horses. The sheep have coarse wool, and no improvement has been recently introduced by fine-woolled rams. The cows are numerous, and afford good butter and cheese, and furnish oxen for the ploughs. As much flax and hemp are raised as is required by the inhabitants to supply the cloths and furniture made of those substances, which are spun in all the houses, and converted into cloth by itinerant weavers. The mines are a great source of wealth, and furnish the chief occupation to the poorer classes. The salt-mines are a part of that vast vein of rock-salt which commences in Wallachia, and extends to Wieliczka in Poland. From six shafts are annually extracted 1,000,000 quintals of this substance, of which nearly three fourths are sent to the provinces of Hungary, and to the Bannat. The other mines are those of gold and silver, yielding, of the former nearly 20,000, and of the latter 40,000 ounces yearly. The copper-mines yield about 3000 quintals, those of lead 2500 quintals, and those of iron 70,000 quintals. Besides these, sixty quintals of quicksilver are prepared. Much of the gold is obtained by washing the sand of the rivers, a labour in which the Gypsies excel. The proprietors and directors of the mines are for the most part Germans. It is an aristocratic country, like Hungary, and, as there, the nobility are exempt from many of the taxes; and the higher clergy of the established sects are considered as noble, but not the monks or pastors. The nobles form the legislative assembly, but can enter into no affairs but such as are suggested by the prince. With his approval, the laws may be amended or repealed, or new laws made. The prince has the sole power of making peace or war, of coining money, of conferring clerical dignities, and of granting dispensations for marriages, and is the heir of the landed property of all families that become extinct. Appeals may be made from the courts of law in Siebenbürgen, as in Hungary, to the high court of chancery, which sits at Vienna. The emperor, as prince, derives an income of L.130,000 from taxes and tithes on minerals and salt, and, besides, has the hereditary land revenues, and from the whole draws annually the sum of nearly L.500,000. According to the last calculation, at the end of the year 1836, the whole population amounted to about 2,250,000 persons. The principal cities, with their population, were,

Kronstadt, or, in Hungarian, Kruhnen	30,000
Klausenburg or Kolosvar	20,000
Hermanstadt	16,000
Thorenberg or Thordaz	7,000
Strasburg or Nagy-Enyed	6,000
Carlsburg	6,000
Schasburg	6,000
Mediasch	5,000
Mullenbach	5,000

On the borders of this principality, as on the other frontiers of the Austrian dominions that are in contact with the Turks, there are what are called military colonies. These consist of soldiers who are furnished with houses and small farms, which they cultivate for their maintenance, having no pay, but the land rent-free. They are armed and clothed by the government, and being regimented, are always prepared to repel any insult from their neighbours, and to suppress any kind of disturbance. The colonists on the Siebenbürgen boundary compose five regiments, four of which are infantry, and one hussars. The staff of each regiment has its head-quarters fixed at one of the small towns on the frontier. The whole number of these colonists, including wives, children, and dependants, with colonists discharged from the service from age or other causes, is estimated at 135,000 persons. They form an active and economical militia-force.

TRAPANI, a city of the island of Sicily, in the province of Mazzara, the capital of an intendancy of the same name. It stands on a long and low isthmus, on the seashore, in a healthy spot. It is surrounded with walls, and defended by a strong castle. Trapani contains forty-two churches and monasteries, several hospitals, and a seminary or college, with 4356 dwellings, and 24,350 inhabitants. The chief occupations are the tunny and the anchovy fisheries, working in coral and marble, making soap, oil, and salt, and shipping corn. The harbour is good and safe, and is protected by a mole. Long. 12. 30. 18. E. Lat. 38. 1. 53. N.

TRAPEZIUM, in *Geometry*, a plane figure contained under four unequal right lines.

TRAS LOS MONTES, one of the provinces into which the kingdom of Portugal is divided. It receives the name from its situation beyond the mountain which divides it from the province of Beyra, in the same kingdom. On the northern frontier it is bounded by Galicia, and on the eastern by Leon in Spain. Its extent is 455 square leagues, and its population 318,665 souls.

TRAU, a city of the Austrian province of Dalmatia, in the circle of Spalatro. It stands on an island, and is connected by a bridge on one side with the mainland, and b another on the opposite side with the island Bua. It i about eight leagues south of Sabenico; and the country around it is highly fertile, producing abundance of corn wine, figs, almonds, and oil, and some wool and cheese. It is the seat of a bishop, who has a palace and a cathedral Trau contains several other churches, and 6300 inhabitants partly occupied in the fishery. The harbour is secure fo small vessels. The steeple of the cathedral is in long. 16 15. 10. E. and lat. 43. 30. 57. N.

TRAVALLA, a seaport on the west coast of the islan of Celebes, containing 200 inhabitants, and carrying on a inconsiderable trade. Lat. 1. 10. S.

TRAVANCORE, a province situated at the south-wes extremity of Hindustan, between the eighth and tenth degrees of north latitude. It is bounded on the north by th territories of the Cochin rajah; on the south and west b the sea; and on the east by a range of woody mountain by which it is divided from the British district of Tinnevelly. It is estimated to extend 140 miles in length b forty in average breadth. The country possesses a diversified surface, and exhibits in the vicinity of the mountain a varied scene of hill and dale, with winding streams whic flow from the hills, and give to the valleys a perpetual ver

lure. The mountains are covered with lofty forests, which
enhance the grandeur of the scene, and which produce pep-
er, cardamoms, cassia, frankincense, and other aromatic
ums. These woods afford ample cover for the wild ani-
nals, which are found here in abundance, namely, ele-
hants, buffaloes, and tigers of the largest size; also mon-
eys and apes, which keep together in flocks. The climate
s so moist that the cultivation of rice is conducted with-
ut the aid of tanks. It is produced in great abundance,
nsomuch that, according to the statement of the natives,
he whole government expenses, civil, military, and reli-
ious, are defrayed from the wet cultivators alone, without
nfringing on the revenues which arise from those articles
hat are produced from the dry mode of culture, which are
epper, betel-nut, cocoa-nut trees, &c. The timber forests
f Travancore are in general farmed, the revenue varying
ccording to circumstances. Among other articles of mono-
oly are ginger, coir, turmeric, and dried cocoa-nut kernels.
obacco for consumption is generally brought from Cey-
n. In the interior of the country, duties are exacted on
e transit of all articles, and the payment at one place
carcely ever exempts the trader from a repetition at an-
ther. The articles which are taxed are cassia-buds, mace,
ng nutmegs, wild saffron, coculus indicus, narwally, bees'
ax, elephants' teeth, and sandal-wood. Custom-duties are
lso imposed, and are let out to farm. There are various
ther sources of revenue, such as taxes on Christian festi-
als, and upon nets and fishermen. But the most import-
nt is a capitation tax on all males from sixteen to twenty,
ith the exception of Nairs, Moplays, and artificers. The
umber taxed is estimated at 250,000. The sum-total of
ll these exactions is computed to amount to twenty lacs of
upees, or L.250,000, besides the taxes on the wet culti-
ation. The principal seaports in this province are An-
ngo, Coulan, Aibecca, and Coleshy. The ancient capi-
l of the country was Travancore, but the rajah now
enerally resides at Trivandapatam. On the coast there
e strong currents, which frequently carry ships round
ape Comorin to a considerable distance westward. This
eing one of those countries which the Mahommedan war-
ors never succeeded in conquering, the primeval manners
f the Hindus are retained in greater purity than in those
thers to the north, whose laws and religion have long
een trampled under foot by their barbarous conquerors.
t a very early period the Christian religion gained a foot-
g in Travancore; and it is now computed that 90,000
ersons have become proselytes to its doctrines. In some
arts, churches are so numerous, and Hindu temples so
re, that the traveller with difficulty believes himself to
e in India. A great proportion of the fishermen on the
a-coast of Travancore and Malabar are considered as
hristians.

The territories of the Travancore chief were formerly of
nall extent, and he paid tribute to Madura; but from
740 to 1755, the ruler extended his territories, owing to
series of military successes, as far north as the boun-
aries of Cochin. In 1790 Travancore was attacked by
ippoo, who, having penetrated to Virapelly, would, but
r the interference of Lord Cornwallis, have wholly sub-
ued the province. In 1795 a treaty of alliance was con-
luded between the rajah and the British; and in conse-
uence of some disputes, into which it is unnecessary to
nter, a war took place in 1809, when the British troops
ok possession of the country with little opposition. The
apital, which bears the same name, was formerly an exten-
ive city, but is now much decayed, since the rajah removed
is residence. Long. 77. 22. E. Lat. 8. 25. N.

TRAVERSE, or TRANSVERSE, in general denotes some-
hing that goes athwart another; that is, crosses and cuts
t obliquely.

TRAVERSE, in *Navigation*, implies a compound course, or an assemblage of various courses, lying at different angles with the meridian.

TRAVERSE *Board*, a thin circular piece of board, marked with all the points of the compass, and having eight holes bored in each, and eight small pegs hanging from the centre of the board. It is used to determine the different courses run by a ship during the period of the watch, and to ascertain the distance of each course.

TRAVESTY, a name given to a humorous translation of any author. The word is derived from the French *travestir*, to disguise.

TREACHEROUS BAY, a dangerous bay in the Eastern Seas, in Gaspar's Strait. It is on the east coast of the island of Billiton, and is full of banks and shoals, many of which are only seen at low water.

TREASON, a general appellation to denote not only offences against the king and government, but also that accumulation of guilt which arises whenever a superior reposes a confidence in a subject or inferior, between whom and himself there subsists a natural, a civil, or even a spiritual relation; and the inferior so abuses that confidence, so forgets the obligations of duty, subjection, and allegiance, as to destroy the life of any such superior or lord. Hence treason is of two kinds, *high* and *petty*.

High Treason, or *Treason Paramount* (which is equivalent to the *crimen læsæ majestatis* of the Romans, as Glanville denominates it also in the English law), is an offence committed against the security of the king or kingdom, whether by imagination, word, or deed. In order to prevent the inconveniences which arose in England from a multitude of constructive treasons, the statute 25 Edw. III. c. 2, was made; which defines what offences only for the future should be held to be treason.

Petty or *Petit Treason*, according to the statute 25 Edward III. c. 2, may happen three ways: by a servant killing his master, a wife her husband, or an ecclesiastical person (either secular or regular) his superior, to whom he owes faith and obedience.

TREASURE, in general, denotes a store or stock of money in reserve.

TREASURE-Trove, in *Law*, derived from the French word *trouver*, to find, called in Latin *thesaurus inventus*, is where any money or coin, gold, silver, plate, or bullion, is found hidden in the earth or any private place, the owner thereof being unknown; in which case the treasure belongs to the king: but if he that had hid it be known, or afterwards found out, the owner and not the king is entitled to it.

TREASURER, an officer to whom the treasure of a prince or corporation is committed to be kept and duly disposed of, in payment of officers and other expenses.

The lord high treasurer of Great Britain, or first commissioner of the treasury, when in commission, has under his charge and government all the king's revenue which is kept in the exchequer. He holds his place during the king's pleasure, being instituted by the delivery of a white staff to him. He has the check of all the officers employed in collecting the customs and royal revenues; and in his gift and disposition are all the offices of the customs in the several parts of the kingdom; escheators in every county are nominated by him; and he also makes leases of the lands belonging to the crown.

TREASURER of the Household is an officer who, in the absence of the lord-steward, has power, with the comptroller and other officers of the board of green-cloth, and the steward of the Marshalsea, to hear and determine treasons, felonies, and other crimes committed within the king's palace.

TREASURER of the Navy, is an officer who receives money out of the exchequer, by warrant from the lord high treasurer, or the lords commissioners executing that place, and pays all charges of the navy, by warrant from the principal officers of the navy.

TREASURY, the place where the revenues of a state are received, preserved, and disbursed. In England the treasury is a part of the exchequer, by some called the *lower exchequer*.

Lords of the TREASURY. In lieu of one single director and administrator of the sovereign's revenues under the title of *lord high treasurer*, it is at present thought proper to put that office in commission, *i.e.* to appoint several persons to discharge it, with equal authority, under the title of *Lords Commissioners of the Treasury*.

TREASURY *Islands*, a small group, consisting of five or six islands of very unequal size, forming part of Solomon's Islands. They are low, and covered with trees. That on the north is the lowest. Its middle is in long. 155. 29. E. Lat. 7. 23. S.

TREATY, a covenant between two or more nations; or the several articles or conditions stipulated and agreed upon by two sovereign powers.

TREBISOND, a considerable trading city of Asia Minor, on the coast of the Black Sea. It is of an oblong shape, and occupies a slope gently rising from the sea. The houses are mostly built of stone and lime. They are roofed with small red tiles, and are mean in their outward appearance and comfortless within. It carries on a considerable trade; and the principal exports are silk and cotton stuffs manufactured by the inhabitants, also fruit and wine. The imports are sugar, coffee, and woollen cloths from Constantinople; corn, salt, and iron from the Crimea and Mingrelia. It contains eighteen large mosques, eight khans, five baths, and ten small Greek churches, governed by a metropolitan. But the most curious edifice in the city is a huge structure, with two small windows on each face. It is supposed to have been erected for a powder magazine. On the east and west the city is defended by two deep ravines, connected by a ditch cut in the rock behind the castle. The ancient ramparts of the city, which are built of stone, are in general very lofty. At the southern extremity of Trebisond is the citadel, which commands a full view of the city and environs. Behind the city, rise mountains of a moderate elevation, which are in a high state of cultivation, producing barley, flax, and wine. The population of Trebisond amounts to 15,000, and consists of a mixture of Turks, Greeks, Jews, Armenians, Georgians, Mingrelians, Circassians, and Tartars. Long. 39. 43. E. Lat. 37. 23. N.

TREBLE and TREBLE-CLEF, in *Music*. See MUSIC.

TREDGOLD, THOMAS, an able engineer, was born at Brandon, near Durham, where he received the small share of learning which is usually bestowed upon a youth destined to a mechanical trade. At the age of fourteen he was apprenticed to a carpenter in his native village, whom he served for six years. He afterwards came to Scotland, where he worked five years as a journeyman. From Scotland he proceeded to London, and there obtained employment in the office of an architect, with whom he remained for ten years. The intervals of labour are too often wasted by artisans in listless inactivity or debasing pleasures; but Tredgold employed his leisure hours in a very different manner. Under circumstances as little favourable for such pursuits as can well be imagined, he applied himself to the study of chemistry, geology, and the mathematics; with what success is well known, and has been acknowledged by the most competent judges in this country, in America, and in France, where many of his works have been translated. When he began to practise as an engineer, we know not; but it was during the period in which he was so engaged that he published the scientific treatises, which have entitled him to an honourable place among those who have made important exertions for the advancement of the useful arts. We subjoin a list of his principal publications. Elementary Principles of Carpentry. Lond. 1820, 4to. Practical Essay on the Strength of Cast Iron, and other Metals. 1824, 8vo. Principles of Warming and Ventilating Public Buildings, &c. Second Edition. 1824, 8vo. A Practical Treatise on Railroads and Carriages. 1825, 8vo. The Steam Engine, comprising an Account of its Invention and progressive Improvement; with an Investigation of its Principles, &c. 1827, 4to. Treatise on the Steam Engine, in 2 vols. 4to. Tracts on Hydraulics. He was likewise the author of some valuable contributions to the present work. He died in the year 1834; and it is painful to add, that, notwithstanding the unwearied exercise of his talents, he left his family without any adequate provision.

TREE. See PLANTING, TIMBER, and VEGETABLE PHYSIOLOGY.

TREGONEY, an ancient decayed borough and market-town of the hundred of Powder, in the county of Cornwall, 253 miles from London. It is situated on the river Fal, and contains places of worship for the established church, and for Independents and Wesleyan Methodists. It formerly returned two members to parliament. There is a small market on Saturday. The population amounted in 1821 to 1035, and in 1831 to 1127.

TREMAN, a town in the Carnatic, situated on the north bank of the Coleroon, twenty miles north-north-east from Travancore. Long. 79. 20. E. Lat. 11. 1. N.

TRENCHES, in fortification, are ditches cut by the besiegers, that they may approach the more securely to the place attacked; whence they are also called *lines of approach*.

TRENT, a city of the Austrian province of Tyrol. It was formerly the capital of an independent ecclesiastical state. The extent was small, but the bishop was a member of the German empire. In the year 1803 it was secularized and united to the Austrian dominions, being incorporated with the province of Tyrol. It afterwards shared the fate of the other Austrian territories in that quarter, till the peace of 1814 placed it in the condition in which it is now to be seen. The bishop is still called a prince, and has a yearly income of about L.4000 sterling. The city lies in a deep valley surrounded with lofty hills, whose sides are covered with vineyards, intermixed with numerous and some elegant country seats and gardens. It stands on the banks of the river Etsch or Adige, which is navigable to it, and over which is a fine bridge 300 feet in length. The city is surrounded with walls, but is not deemed capable of defence, from the heights that command the works. The streets are narrow, gloomy, and not very clean. The palace of the bishop is an antique and unsightly building, but adorned by fine gardens. The cathedral is highly ornamented, and worth seeing; and in the church of Santa Maria is a remarkably fine painting, in which are portraits of the most distinguished members of the celebrated council held at this place. There is a collegiate establishment or lyceum, in which are thirteen professors teaching philosophy and theology. Being on the great road from Italy to Germany, it has much commerce, including some by the river, and a few considerable silk manufactories. It contains 760 houses and 9850 inhabitants. From the great heat of summer, and the severe cold of winter, it is not found to be a healthy place.

TRENT, *Council of*, in *Ecclesiastical History*, denote the council assembled by Paul III. in 1545, and continue by twenty-five sessions till the year 1563, under Julius III and Pius IV. in order to correct, illustrate, and fix with perspicuity, the doctrine of the church, to restore the vigour of its discipline, and to reform the lives of its ministers. The decrees of this council, together with the creed of Pope Pius IV. contains a summary of the doctrines of th Roman Catholics. These decrees were subscribed by 25 clergy, consisting of four legates, other two cardinals, thre patriarchs, twenty-five archbishops, 168 bishops, besides inferior clergy. As 150 of these came from Italy, the counc was entirely under the influence of the pope. For a mor articular account of the council of Trent, see the elaborate stories of Sarpi and Pallavicino. The former of these is very remarkable work. For the history of this council, great mass of materials was collected by Le Plat: "Mo- mentorum ad Historiam Concilii Tridentini potissimum ustrandam spectantium amplissima Collectio." Lovanii, 781-7, 7 tom. 4to.

TRENT, one of the largest rivers in England, which ses in the moorland of Staffordshire, and runs south-west Newcastle-under-Lyne; and afterwards dividing the coun- into two parts, runs to Burton, then to Nottingham and ewark; and so continuing its course due north to Gains- rough on the confines of Lincolnshire, it joins several vers, and falls into the Humber.

TRESTLE TREES, in ship-building, two strong bars timber fixed horizontally on the opposite sides of the wer mast-head, to support the frame of the top and the eight of the topmast.

TRESSURE, in *Heraldry*, a diminutive of an orle, sually held to be half the breadth thereof.

TRET, in *Commerce*, an allowance made for the waste the dirt that may be mixed with any commodity; which commonly four pounds in every 104 pounds weight.

TREVANNION'S ISLAND, one of the group called ueen Charlotte's Islands, in the South Pacific Ocean, dis- overed by Captain Carteret in 1767. Long. 163. 43. E. at. 10. 43. S.

TREVENNEN'S ISLAND, the most southern of the Mar- esas Islands, in the South Pacific Ocean. Long. 220. 1. E. Lat. 9. 14. S.

TREVES, a district in Prussia. See TRIER.

TREVIGLIO, a city of the north of Italy, in the Aus- ian kingdom of Milan and the delegation of Bergamo. stands on the river Adda, in a district that is not very roductive of any other article but silk, of which a great uantity is supplied and disposed of at an annual fair. Tre- iglio contains but one church, but has an hospital. The habitants are 6700, who are employed in making linen nd silk goods of various kinds.

TREVISO, a delegation of the Austrian kingdom of Lom- ardy, which extends over 721 square miles, and contains 51,600 inhabitants, and yields abundance of corn, oil, ine, and silk. The capital is the city of the same name n the navigable river Sil, where the Rottinga and the Piave-Sella pour into it their streams. It is ancient and l built, is surrounded with walls, and has large plazas, ith houses built on piazzas. It contains a cathedral and wenty-seven other churches, several monasteries and con- ents, and 2600 houses, with 15,100 inhabitants, who are hiefly employed in the various branches of the silk trade, ut also print calicoes, make cottons, linens, and cutlery ware. t has a great annual fair. Long. 11. 8. 10. E. Lat. 45. 9. 30. N.

TREVOU, an arrondissement in the department of the Ain, in France, extending over 592 square miles. It con- ains seven cantons and 111 communes, with 77,530 inha- itants in 1836. The capital, which is the city of the ame name, stands on the left bank of the Saone, on a range f hills covered with the finest vineyards. It contains 559 inhabitants, who make many parts of the works of locks and watches, and draw wire of gold and of silver. Long. 5. 5. 45. E. Lat. 45. 56. 42. N.

TRIER, or TREVES, a very ancient city of Germany, the *Augusta Trevirorum* of the Romans, who made it their ead-quarters against the Germans, and the residence of ome of their monarchs. Under the kings of the Franks t was afterwards a city of great consequence. It was subsequently the chief residence of the prince archbishop, an ndependent member of the German empire. It was seized by the French at the beginning of the Revolution, and by the peace of Luneville in 1801 was ceded to France. In 1824 it was occupied by the allied armies, and by the treaty of Vienna was eventually ceded to Prussia. It is now the capital of a district or circle of its name in the Prussian province of the Lower Rhine, which extends over 2786 square miles, and in 1834 contained 437,324 inhabitants, of whom 50,000 are Protestants, and all the rest of the Romish church. The city is situated in a pleasing valley on the river Moselle, which is here navigable for barges of 100 tons. It is the seat of a bishop and of the provincial courts of law, and has an ecclesiastical seminary. Within the city are many large gardens, which give it the appearance of a Swiss town, and add greatly to its beauty. The inhabitants amounted in 1834 to 14,723. Among the buildings are many curious specimens of very ancient architecture. The palace of the prince bishop, now the barracks, is one of them; and another is the church of the Virgin, in the peculiar old German taste. The cathedral is of a very irregular form, but contains some beautiful altars, and a fine gallery of marble. The church of St Simon is of Roman architecture. Though a church, it is also a gate, the *Porta Nigra*, the most remarkable specimen of architecture in Germany. Other Roman antiquities are, an amphitheatre in ruins, some baths, and several gates of antique edifices. Few places afford more delight to the lovers of antiquities.

TRIAD, in *Music*, the common chord. See MUSIC.

TRIAL, in *Law*, the examination of a cause according to the laws of the land, before a proper judge; or it is the manner and order observed in the hearing and determining of causes.

TRIANGLE, in *Geometry*, a figure of three sides and three angles.

TRIANGLE. See the article MUSIC.

TRIBE, a certain quantity or number of persons, when a division is made of a city or people into quarters or districts.

TRIBOLI, a town of Asia Minor, on the coast of the Black Sea, curiously built; the houses being scattered along the edges of the precipices and sides of the mountains. The town contains two handsome khans. The port is good, and vessels may ride securely in it in stormy weather. The surrounding hills, though they are uncultivated, afford good pasturage for numerous flocks of sheep and goats. The town contains 400 families. It is seventy-two miles east of Trebisond.

TRIBRACHYS, in ancient poetry, a foot consisting of three short syllables; as, *melius*.

TRIBUNAL, in general, denotes the seat of a judge, called in our courts the *bench*.

TRIBUNE, among the ancient Romans, a magistrate chosen out of the commons, to protect them against the oppressions of the great, and to defend the liberty of the people against the attempts of the senate and consuls. The tribunes of the people were first established in the year of Rome 259. The design of their creation was to shelter the people from the cruelty of usurers, and to engage them to quit the Aventine Mount, whither they had retired in displeasure. Their number at first was only two; but the next year, under the consulate of A. Posthumius Aruncius and Cassius Viscellinus, three more were added; and this number of five was afterwards increased by L. Trebonius to ten. See ROMAN HISTORY.

Military **TRIBUNE**, an officer in the Roman army, commander-in-chief over a body of forces, particularly the division of a legion; much the same with our colonel.

TRIBUTARY, one who pays tribute to another in order to live in peace with or share in his protection.

TRIBUTE, a tax or impost which one prince or state is obliged to pay to another as a token of dependence, or in virtue of a treaty, and as a purchase of peace.

TRICHINOPOLY, a celebrated town and fortress in

Tricolor
||
Trieste.

the Southern Carnatic, advantageously situated on the south bank of the river Cavery, opposite to the island of Seringham, famous for its magnificent Hindu temples. This city was formerly the capital of a Hindu principality, until 1736, when Chunda Saheb, the prime minister of the nabob of the Carnatic, acquired it by treachery. It was taken possession of by the Mahrattas in 1741, but lost by them to the Mahommedans in 1743. The town is situated on a hill or rock about 350 feet high, and was esteemed impregnable by the natives. In 1749 it devolved by inheritance to the Nabob Mahommed Ali; and it sustained a memorable siege by the French and their allies, which lasted from 1751 until 1755, in the course of which were displayed the great military talents of Laurence, Clive, and other officers, which had the effect of preserving the city, and of establishing a British candidate on the throne of the Carnatic. At present Trichinopoly is the capital of one of the districts into which the territory under the Madras presidency has been subdivided. The surrounding country is rendered productive by the vicinity of that branch of the Cavery named the Coleroon. It has a strong garrison of both native and European troops, and is the residence of the civil authorities of the district. It contains a palace, a mosque, and two temples. Travelling distance from Madras 268 miles, from Seringapatam 205, and from Calcutta 1238 miles. Long. 78. 50. E. Lat. 10. 50. N.

TRICOLOR, a town of Hindustan, in the Carnatic, forty-four miles west from Pondicherry. Long. 79. 20. E. Lat. 11. 59. N.

TRIDENT, a kind of sceptre which the painters and poets put into the hands of Neptune, in the form of a spear or fork with three teeth; whence the word.

TRIENNIAL, an epithet applied chiefly to offices or employments which last for three years.

TRIENS, in *Antiquity*, a copper money of the value of one third of an *as*, which on one side bore a Janus's head, and on the other a water-rat.

TRIESTE, one of the governments into which the Austrian kingdom of Illyria is divided. It forms the most southern part of that kingdom, and comprises the whole of the sea-shore of the dominions of Austria, extending from Grado to Novi; and there have been added portions of Venetian Friaul, both the Istrias, part of Krain, with such portions of the district of Agram as are on the right bank of the river Save, and the Quarnaro islands of Cherso and Veglia, with their dependencies. The government is distributed into four circles, viz. Gorz, Istria (in which is the city of Trieste), Fiume, and Karlstadt. The whole extent of the country is 4972 square miles, and it comprises twenty-nine cities now or once fortified, forty-one market-towns, 1193 villages, 93,493 houses, and 598,970 inhabitants. The population is of various original races, but the rural people are for the most part of the Illyrian nation, and speak only the language of that tribe. They mostly adhere to the Romish church, while in the cities there are Protestants, Greek Christians, Jews, and Mahommedans, who are all tolerated. The country is mountainous but fertile, and in the south yields abundance of olive oil, some wine, and some silk. The government does not produce sufficient corn for its consumption, but is well supplied from the neighbouring Austrian territories, or occasionally from the Black Sea, by imports at Trieste and at Fiume.

TRIESTE, a maritime city, the capital of the department of the same name in the Austrian kingdom of Illyria. It is an open city, on the sea-shore, at the bottom of a deep bay at the head of the Adriatic Sea. The shore here forms a semicircle, around which Trieste is built, and rises like an amphitheatre, in a picturesque style, with lofty hills on both sides of it. The town is beautiful, the streets are wide and clean, and the houses generally high and well built. Though without walls, it is defended by a strong citadel on a hill to the south, which commands the city. The public buildings, except the cathedral and some other of the churches, are by no means very splendid, but convenient and appropriate. Such are the palace, the custom-house, the theatre, and, especially remarkable for its extent and accommodations, the lazaretto. The last mentioned building deserves more notice, as being held the most complete of the institutions to prevent the introduction of the plague, that are to be seen in any part of the Mediterranean. This pile, which was built in 1785, is cut off from all intercourse with the inhabitants by a high wall, which entirely encircles it. It has a spacious harbour, well sheltered by a strong mole, and is strictly guarded. The governor has a house within the precincts, and is bound to go the rounds three times every night, in order to see that the guards do their duty. Extensive magazines are attached to it for the exposure of goods. It contains thirty-two sets of apartments for passengers, who are locked in every night. The captains and crews of ships are permitted (always with a guard) to go on shore and walk in a large square appropriated to them, and separated by a high wall from another which is designed for the passengers who have left the ships. Every Sunday the crews of the vessels are allowed to come on shore to attend mass in the chapel of the lazaretto, but with every requisite precaution. In the bay of Trieste there is good anchorage over the greater part, varying from seven to fourteen fathoms of water, with a muddy bottom. The best spot is in seven fathoms, when the citadel and the theatre are in a line from it. The harbour is formed by a mole lying to the northward before the city. It is very large, and capable of containing a great number of vessels. It is somewhat exposed to the north-west and north winds, but is protected from westerly winds by the long mole, on which is a battery. There is a canal running nearly through the centre of the city, where vessels haul in to load and unload.

Trieste was first made a free port in 1719, but was an inconsiderable place, with not more than 6000 inhabitants, till 1753, when the Empress Maria Theresa improved and enlarged it by a great variety of expensive operations. It has since risen to its present condition, and is the chief place of sea-communication with the rest of the world for the extensive dominions of the house of Austria. It is said to have thirty-one plazas, 214 streets, seven Catholic churches, one each for the Greek, the Lutheran, and the reformed religion, and 58,600 inhabitants. They are principally composed of Germans and Italians, but persons from almost every country are to be found domiciled. There are said to be seventeen banking and insurance companies, 1000 mercantile houses of all kinds, and 17,000 authorized and sworn brokers, who act also as interpreters.

The foreign trade is extensive. Mr Money, the late English consul-general, calculated the value of the goods imported to amount to L.1,800,000 annually, and that of the goods exported to be nearly equal; but this has been commonly deemed to be less than the actual value, especially as regards the imports, which some authorities have estimated as high as L.4,000,000, including such as are afterwards transhipped to the other Austrian ports on the Adriatic, such as Venice, Fiume, and the islands on the coasts of Dalmatia. The articles of gunpowder, salt, and tobacco are monopolized by the government, and are not allowed to be imported but by the contractors, who are under the finance department. Great vigilance is used to prevent the introduction of those commodities, and an equal or greater degree of activity prevails among contraband traders to supply them to the public; the high prices which the government demand of the consumers acting as an incentive to evade or defy the restrictions.

TRIGLYPHS, in *Architecture*, a sort of ornament repeated at certain intervals, in the Doric frieze.

TRIGONOMETRICAL SURVEY.

Any survey of a country, which is carried on from a single base by the computation of observed angular distances, may be properly called a trigonometrical survey; but the term is usually confined to measurements on a large scale, embracing a considerable extent of country, and requiring a combination of astronomical and geodetical operations.

There are two principal objects for which a trigonometrical survey may be undertaken; the first being to ascertain the exact situation of the different points of a country relatively to each other, and to the equator and meridians of the terrestrial spheroid, for the purpose of constructing an accurate map; and the second to determine the dimensions and form of the earth, by ascertaining the curvature of a given portion of its surface. Having already, in the article Figure of the Earth, given a general account of the principal operations, which, in different ages and countries, have been undertaken with a view to the second of these objects, and also explained the methods by which the elements of the earth's form and dimensions are computed from the geodetical measurements, and stated the results which are deducible from those measurements taken collectively, we shall not, in the present article, enter into the general subject of Geodesy, but shall confine ourselves to a more particular account than could have been properly given in the article cited, of the great survey which during the last half-century has been carrying on in our own country under the direction of the Board of Ordnance. We accordingly propose to give, in the first place, a brief abstract of the history of that operation, so far as it may be collected from the accounts published in the Transactions of the Royal Society, and in the three volumes of the work entitled "The Trigonometrical Survey of England and Wales;" and, in the second place, to explain the methods by which the distances, latitudes, longitudes, bearings, and relative heights of the several positions are computed from the observations. The subject, though somewhat technical, is important both in a scientific and national point of view; and few persons, perhaps, have any just notions of the extremely refined nature of the operations to be executed, or of the difficulties to be surmounted, when the question is to determine terrestrial distances and positions with the extreme precision which alone can be tolerated in the present advanced state of mathematical and astronomical science.

From the account given by General Roy, it appears that the origin of the British trigonometrical survey goes back to the middle of the last century. The rise and progress of the rebellion which broke out in the Highlands of Scotland in the year 1745, convinced government of the importance of establishing military posts, and opening roads of communication in the remotest parts of the country; and a body of infantry having been encamped at Fort Augustus in 1747 with a view to these objects, Lieutenant-general Watson, who was then officially employed at that place as deputy quartermaster-general, conceived the idea of making a map of the Highlands. The proposal having met with the approval of the Duke of Cumberland, the survey necessary for the purpose was forthwith commenced under the direction of General Roy; and although it was originally intended to confine the operation to the Highlands, it was nevertheless extended to the Lowlands, and at length included the whole of the mainland of Scotland. The breaking out of the war in 1755 prevented the survey from being completed, and accordingly the projected map was never published. General Roy states, that although the work, which exists in manuscript, possesses considerable merit, and perfectly answered the purpose for which it was intended, yet, having been carried on with instruments of a common or even inferior kind, it is rather to be considered as a magnificent military sketch than a very accurate map of a country.

Trigonometrical Survey.

On the conclusion of the peace of 1763, the question of making a general survey of the whole island came for the first time under the consideration of the government; but although the utility of such a measure was acknowledged, no steps were taken to carry it into effect until after the termination of the American war in 1783. During this year a memorial, drawn up by Cassini de Thury, was transmitted by the French ambassador to Mr Fox, then Secretary of State for the Foreign Department, setting forth the advantages that would accrue to astronomy by carrying a chain of triangles from the neighbourhood of London to Dover, to be connected with those of the French arc of meridian, which had now been extended from Collioure to Dunkirk, and thereby determining, by actual measurement, the relative positions of the Observatories of Greenwich and Paris. Cassini's proposal having been referred to the Royal Society, was warmly approved by that body; in consequence of which the government undertook to give the requisite assistance, and the execution of the operation was committed to General Roy, who was then employing himself in the measurement of a base for a projected survey of London, which he had undertaken with a view to connect the different private observatories in and about the capital with that of Greenwich, and, as he states, "that it might possibly serve as a hint to the public for the now almost forgotten scheme of 1763."

Although the operation which was thus resolved upon did not embrace a general survey of the kingdom, but was confined to the particular object of effecting a junction of the Greenwich Observatory with the French triangulation, it was still an object of great astronomical interest; and accordingly it was determined that the measurement should be conducted with the utmost possible care in all its details, and with the best instruments which could be provided by the celebrated Ramsden, at that time acknowledged to be the first artist in the world.

Base on Hounslow Heath.

The first step in the operation was the accurate measurement of a base, from which the sides of a chain of triangles might be successively computed. For this purpose General Roy selected a line on Hounslow Heath, a situation which presented the advantages of proximity to the capital and the Observatory of Greenwich; of great extent and levelness of surface; of being free from local obstructions, and commodiously situate for any future operations of a similar nature. The line extended from a place called King's Arbour, at the north-west extremity of the Heath, and terminated at Hampton poor-house, near Bushy Park, at the south-east extremity, the whole length being upwards of five miles.

Measurement with deal rods.

The preliminary operations having been completed, and the terminal points having been marked by sinking wooden pipes into the ground, the measurement was commenced about the middle of July 1784. The measuring apparatus consisted of three deal rods, on which lengths of twenty feet were laid off by Ramsden, and a standard rod, with which the former were from time to time to be compared. The measuring rods were formed out of an old mast of Riga timber, their dimensions being 20 feet 3 inches in length (including the tippings, which were of bell-metal), about 2 inches deep, and

1¼ inch broad, and trussed both laterally and vertically, so as to be rendered perfectly inflexible. They were constructed in such a manner that they might be used either by butting the end of one rod against the end of another, or by bringing fine transverse lines drawn upon them at the distance of an inch and half from each extremity into exact coincidence; but although the last method was considered by General Roy to deserve the preference, it was found on trial to be attended with so much inconvenience and loss of time that it was abandoned, and the measurement by contacts alone adhered to. The weather proved wet and unfavourable, and before the measurement was half completed, the deal rods were found, notwithstanding all the care which had been taken to prepare them of the best materials, so liable to sudden and irregular variations of length, from changes in the hygrometrical state of the atmosphere, as to leave no hopes of determining by their means the length of the base with the precision which was aimed at. As, however, so much of the work had been done, it was thought desirable to continue it until the whole base was measured, in order that the result might be compared with that which should afterwards be found by a different method

Expansion of deal rods.

General Roy cites some experiments to show how unfit deal rods are for such a purpose as the measurement of the base of a great trigonometrical operation. On one occasion the measuring rods, when compared with the standard, were found to exceed it, at a medium, one fifteenth part of an inch; so that if the whole base had been measured with the rods in that state, the difference would have amounted to more than 7½ feet, exclusive of any expansion or contraction of the standard, which was of the same material. Another experiment, made after the operation had been completed, was still more decisive. A line of 300 feet was accurately measured off in the garden of Sir Joseph Banks when the rods were in a dry state, the sun shining bright, and the temperature 68°. The rods were exposed to the dew during the night, and when lifted from the grass on the following morning were found to be quite wet excepting on the sides in contact with the ground. The line was then remeasured, and its length as given by the rods found to be less by 0·498 of an inch (or nearly half an inch) than on the preceding evening. Hence it appeared that the dew imbibed in one night, or a period not exceeding fourteen hours, caused such an expansion of the rods as in the whole base would have amounted to 45·484 inches. (Trig. Survey, vol. i. p. 50.) These experiments were important, as deal rods had been employed in all the principal operations of the kind which had previously been undertaken for determining the magnitude and compression of the earth.

The measurement with the deal rods being completed, and the proper allowance (so far as it could be determined from the comparisons with the standard) made for the expansion, the distance between the centres of the pipes terminating the base, reduced to the level of the lower extremity at Hampton Court, and at the temperature of 63°, was found to be 27,406·26 feet of the standard scale from which the lengths of the measuring rods were laid off.

Measurement with glass rods.

When it was discovered that the measurement by means of the deal rods would prove unsatisfactory, and General Roy was considering the different alternatives that might be adopted, it was suggested by Lieutenant-colonel Calderwood that glass rods should be substituted for those of deal. As it was found upon trial that there would be no difficulty in obtaining glass tubes of the desired length, and that they could be provided much sooner than rods of metal; and as it was obvious that the rate of expansion could be determined with equal certainty, it was resolved to adopt the suggestion. Accordingly, three hollow tubes, perfectly straight, upwards of twenty feet in length and about an inch in diameter, were selected, and converted by Ramsden into measuring rods. The tubes were placed in cases, to which they were made fast at the middle, and braced at several other points, so as to prevent them from bending or shaking, but not so closely as to prevent their free expansion or contraction. Both ends were ground perfectly smooth and at right angles to the axis of the bore; one end having a fixed apparatus or metal button attached to it for making the contacts, and the other end a moveable apparatus, or slider, which was pressed outwards by a slender spring, and against which the fixed extremity of the succeeding rod was pushed, until a fine line on the slider was brought into exact coincidence with another fine line on the glass rod, in which state the distance between the extremities was exactly twenty feet.

The ground on which the base was measured not being quite level, the whole distance was divided into hypothenuses or inclined lines in the same vertical plane, each containing thirty lengths of the measuring rods, or 600 feet; and the method pursued was to place the rods exactly in straight lines stretching from one extremity of a hypothenuse to another, and then to determine the relative heights of the two extremities of the hypothenuse by the spirit-level, for the purpose of reducing to the horizon. The cases containing the measuring rods were supported on trestles about two and a half feet above the surface of the ground.

The new measurement with the glass rods was begun on the 18th of August, and concluded on the 30th. On arriving at the south-east extremity, the end of the 1370th rod was found to overshoot the centre of the pipe terminating the base, by 17·875 inches; and after the rate of expansion of the rods had been determined, and the proper equations applied, the difference between the present and the former measure with the deal rods was found to be 20·964 inches, of which the greater part is probably owing to the over-rated expansion of the deal rods, which, when brought into use, appear to have contracted sooner than was imagined, and thereby given a shorter distance than was assignable from the mean of any two comparisons with the standard. No use was made of the measurement with the deal rods in any of the subsequent operations.

After the measurement on the ground had been completed, it was necessary to determine by actual experiments the expansion of the glass rods, in order to obtain the exact length of the base. For this purpose an ingenious microscopic pyrometer, invented by Ramsden, was employed, by means of which the expansion of the brass scale, and of glass rods and various other substances, was ascertained for every degree of Fahrenheit from 32° to 212°. The glass measuring rods could not themselves be submitted to experiment on account of their great length; the rod on which the experiments were made was 5 feet in length, 0·93 inch in diameter, weighing 1 lb. 13½ oz. and drawn from the same pot of metal as the measuring rods. These experiments were made in the winter of 1784 and spring of 1785.

In order to give a clearer idea of the number of minute circumstances to be attended to in an operation of this kind, we shall here state the final result in the words of General Roy. (Trig. Survey, vol. i. p. 84.)

	Feet.
Hypothenusal length of the base as measured by 1369·925521 glass rods of 20 feet each + 4·31 feet, being the distance between the last rod and the centre of the north-west pipe,	27,402·8204
Reduction of the hypothenuses to be subtracted,	0·0714
Apparent length of base reduced to level of south-east extremity..............................	27,402·7490
Add the difference between the expansion of the glass above, and contraction of it below, 62°, 4·1867 inches.......................... =	0·3489

Add also the equation for 6° difference of temperature of the standard brass scale and the glass rods, between 62° and 68°, the temperature at which the glass rods were laid off, 11·8368 in.................................=	0·9864
Length of the base, in temperature 62°, reduced to the level of the lower extremity....	27,404·0843
Reduction from the height of the lower end of the base above the mean level of the sea, supposed to be 54 feet........................=	0·0706
True length of the base, reduced to the mean level of the sea..................................	27,404·0137

In making the reduction to the level of the sea, the mean semidiameter of the earth is assumed to be 3,492,915 fathoms.

With respect to this measurement, General Roy remarks hat " infinite pains were taken, both in the field and otherwise, throughout the whole operation, to obtain a just conclusion ;" and as the means employed appear to be fully adequate to the attainment of the object in view, there eems to be no good reason to doubt that the accuracy of the result corresponded to the skill and attention with which the operation was conducted.

The measurement of the base having been effected, the next object was to proceed with the triangulation ; but a delay of three years intervened before the operations were esumed. In the summer of 1787, the instrument intended or the measurement of the angles (a large theodolite, having ts horizontal circle of three feet in diameter) was completed by Ramsden, and carried to the station at the south end of the base on the 31st of July. Sir Joseph Banks, as president of the Royal Society, had in the mean time put himself n communication with M. Cassini, whom the Academy of Sciences had appointed to co-operate in the junction of the French and English triangles ; but as the season was now oo far advanced to admit of the operation being completed before the winter set in, it was resolved, after a few angles had been observed, to proceed to Dover and Calais to execute the coast triangles, leaving the inland part of the series o be executed afterwards. In this operation General Roy was accompanied by Dr Blagden, and assisted by Mr Isaac Dalby (afterwards professor of mathematics in the Military College), whose ingenuity and scientific knowledge rendered most essential service. At Dover the party was met by Cassini, Mechain, and Legendre, distinguished members of the Academy of Sciences, who had crossed the channel for the purpose of concerting the measures necessary for making reciprocal observations on both coasts. For the distant signals a great number of white lights had been prepared, and also several reverberatory lamps; and the French academicians having been furnished with a sufficient number of the lights for the observations on their side of the channel, returned to Calais on the 25th of September, when the observations were begun. The weather proved extremely unfavourable, but, fortunately, on the particular nights on which the most important observations on the English side were to be made, namely, those at Dover and Fairlight Down, the atmosphere was clear, and the observers were enabled to intersect with great accuracy the French stations of Blancnez in the neighbourhood of Calais, and Montlambert (or Boulemberg), near Boulogne, and thus establish the triangular connexion between the two countries.

After this operation was concluded, the instrument was carried to a few more of the stations ; but two still remained unobserved, when, in the beginning of November, the badness of the weather obliged the party to desist until the following summer. The observations at the two remaining stations were made in the ensuing August.

Base of verification on Romney Marsh.

In order that no precaution should be omitted to insure the accuracy of the operation, it was resolved to measure a base of verification towards the termination of the triangles. The ground selected for this purpose was Romney Marsh, a tract which, on account of its levelness, was exceedingly well suited to the purpose. The marsh had been previously covered by the sea, and a considerable part of it, particularly towards the bottom of the range of hills that separate it from the Wealds of Kent, is still lower than the sea at high water. A preliminary survey of the marsh having been made, a line was selected running from High Nook on the spire of Ruckinge church, and of nearly six miles in length. The terminal points were marked by sinking two wooden pipes into the ground. This base was not measured with the glass rods, but with a steel chain of 100 feet in length, made by Ramsden, and of which the accuracy had been tested by measuring with it a portion of the Hounslow Heath base simultaneously with the glass rods. The measurement was executed by Lieutenant Fiddes of the royal engineers. The apparent length of the base, or that given directly by the measurement, was 28,536 feet 8·835 inches; and after the proper reductions were made, the correct horizontal distance between the pipes, in feet of the standard brass scale, at temperature 62°, and at the level of the sea, was found to be 28,535 feet 8·128 inches.

On connecting the base with the series of triangles extending from Hounslow Heath, its length, as deduced from the former base, was computed to be 28,533·3 feet; so that the computed length fell short of the measured length about twenty-eight inches. This agreement is probably as near as was to be expected, and may be taken as conclusive proof of the general accuracy of the whole of the operations; nevertheless, as there were reasons for supposing that the accuracy attained in the base of verification was not equal to that of the original base, the whole of the triangles were computed from the latter. The measurement on Romney Marsh does not enter as a datum into any of the results of the survey.

Method of observing and computing the triangles.

By reason of the superior magnitude and excellence of the instrument employed, the measurement of the angles was performed with a degree of accuracy which had probably never been equalled in any former survey. Although the reduction to the centre of the station requires a very simple calculation, it was thought desirable to avoid, as much as possible, reductions of every kind, and accordingly the centre of the great theodolite was adjusted by means of a plummet over the precise points marking the stations. The whole number of stations at which it was placed was twenty-three. In nine cases the instrument was elevated to the top of a tower, church steeple, or other building; and in the fourteen other cases, the station was marked by sinking a pipe into the ground, to indicate the precise spot over which the instrument had been placed, in order that the observations might be repeated, or the stations connected with others in any future operation. The sides of the triangles were computed by plane trigonometry ; that is to say, the portion of the earth's surface over which the triangulation extended was regarded as a plane, and the measured bases as straight lines on that plane. This supposition, though in the small portion of surface in question it did not lead to errors of great magnitude, is inadmissible in an extensive survey. The spherical excess was indeed roughly computed for each triangle, but merely for the purpose of showing the amount of the errors of observation ; and the observed angles of each triangle were adjusted so that the sum should equal 180°, by applying to each an arbitrary correction.

Results of the measurement.

The calculation of the triangles, and the determination of the relative positions of the Paris and Greenwich Observatories, with the lengths of the degree of meridian and perpendicular, are given in detail in the Phil. Trans. for 1790 ; but the results are not now of much importance, inas-

Trigonometrical Survey.

much as the whole of the observations have been since repeated and recomputed by more scientific and accurate methods. General Roy's operations gave the difference of longitude between Greenwich and Paris = 2° 19′ 51″, or in time $9^{\mathrm{m.}}\ 19^{\mathrm{s.}}4$. Legendre found, from the same operations, $9^{\mathrm{m.}}\ 21^{\mathrm{s.}}$ (*Mémoires de l'Acad.* 1788). This last determination would appear to be very near the truth, the difference of the two meridians having been found by fire-signals, = $9^{\mathrm{m.}}\ 21^{\mathrm{s.}}46$ (Henderson, Phil. Trans. 1827); by Captain Kater's remeasurement of Roy's triangles, = $9^{\mathrm{m.}}\ 21^{\mathrm{s.}}18$ (Phil. Trans. 1828); and, lastly, by the transit of chronometers from Greenwich to Paris and back, = $9^{\mathrm{m.}}\ 21^{\mathrm{s.}}14$ (Dent, Proceedings of the Astronomical Society, January 1838).

Remeasurement of Roy's triangles.

The account of the remeasurement to which we have just alluded is given by Captain Kater in the Phil. Trans. for 1828. In 1821 the Academy of Sciences of Paris communicated to the Royal Society their desire that the operations for connecting the meridians of Paris and Greenwich should be repeated jointly by both countries; and the proposal having been acceded to, Colonel Colby and Captain Kater were appointed by the Royal Society to co-operate with M. Arago and M. Mathieu, the commissioners chosen by the Academy of Sciences. The requisite assistance having been readily obtained from the Ordnance department, the operations were begun in the autumn of the same year.

The instrument employed on this occasion was the great theodolite belonging to the Royal Society, the same which had been used by General Roy. The signals for connecting the stations on the opposite coasts were lamps with compound lenses, constructed on the principle and under the direction of M. Fresnel; and Captain Kater remarks, that the light far exceeded that of any of our light-houses, appearing at the distance of forty-eight miles as a star of the first magnitude. Having selected convenient stations on Fairlight Down and near Folkstone turnpike, the party carried the instrument across the channel, and observed the angles made at the stations of Cape Blancnez and Montlambert with those on the English coast. They then recrossed the channel, and observed the angles subtended by the signals at Cape Blancnez and Montlambert from the stations on Fairlight Down and Folkstone. After some difficulty, General Roy's station was discovered on Fairlight Down, and the observations at both stations were satisfactorily completed on the 27th of October. These reciprocal observations sufficed to establish the connection between the two countries; and the object now proposed by Colonel Colby and Captain Kater was to connect the triangles with General Roy's base on Hounslow Heath. On examination, the guns marking the termination of the base were discovered; but in consequence of the erection of numerous buildings since 1783, one end of it could not be seen from the other; it was therefore necessary to adopt a side of one of General Roy's triangles as the measure of the linear distances, and that from Severndroog Castle, on Shooter's Hill, to Hanger Hill Tower, was selected, these being the nearest stations to General Roy's base which would be identified with sufficient precision. In the course of the two following summers the angles were observed at all the intermediate stations, and also the observations completed at Greenwich which were necessary for determining the azimuths or bearings of the sides of the triangles in respect of the meridian of the observatory. In the calculation of the triangles Captain Kater made use of the theorem of Legendre (which will be afterwards explained), whereas General Roy's calculations, as already stated, were made by considering the surface a plane. The latter method is obviously incorrect; yet, from the near agreement of the results, it is evident that no differences of any consequence arose from the different modes of computation adopted. The following comparative table of distances given by Captain Kater shews the agreement between the two independent operations. The measures are here given in imperial feet.

Distance from	By Gen. Roy.	By Capt. Kater.	Difference.
	Feet.	Feet.	Feet.
Fairlight to Frant..........	113850·59	113857·34	6·75

Although the geodetical operations which had been carried on by General Roy, might be regarded as subservient to a general survey of the country, they did not form part of any systematic plan for accomplishing that object; and on the death of the General, which took place in 1790, some time elapsed before any measures were taken to prosecute them further. In the introduction to the account of the first part of the survey carried on under the direction of the Board of Ordnance, the renewal of the operations is ascribed to the accidental circumstance of the Duke of Richmond, then master-general, having had an opportunity of purchasing "a very fine instrument, the workmanship of Mr Ramsden, of similar construction with that used by General Roy, but with some improvements; as also two new steel chains of one hundred feet each, made by the same incomparable artist." The new instrument is said[1] to have been ordered by the East India Company for the purpose of surveying their possessions in the East, and Ramsden had exerted all his ingenuity in endeavouring to render it perfect; but some misunderstanding having arisen about the price, the directors refused it, and it was thus thrown on the hands of the artist. The Duke of Richmond having been advised to purchase it for the Ordnance the instrument thus became the property of the public, and has been employed as the principal instrument of the survey down to the present time. It has been already stated, that the instrument used by General Roy was the property of the Royal Society.

In 1791 the Ordnance survey was begun, and its execution committed to Colonel Williams and Captain (afterwards General) Mudge of the Royal Artillery, and Mr Dalby. The first operation which they undertook was the remeasurement of the base on Hounslow Heath. It had been objected to the former measurement, 1st, that some error might be supposed to arise from the ends of the two consecutive rods being made to rest on the same trestle, because when the first rod was taken off the face of the trestle being pressed by one rod only would have a tendency to incline a little forward, the ef fect of which would be to shorten the apparent length o the base; 2d, it was supposed that some error might aris from the casual deviation of the rods from a straight line i the direction of the base; and 3d, it was supposed, that from the manner of supporting the rods on two trestles only, the would be liable to bend in the middle. For these reasons i was determined to remeasure the base by a totally differen method. Instead of measuring rods, the two new stee chains above alluded to were used. These were 100 fee in length, and containing 40 links of 2½ feet each. Th links were in form of a parallelogram of half an inch square and their length was considered advantageous, as ren dering them less liable to apply themselves to any irregu larities of the coffers on which they were supported. T sing the chains, five coffers were arranged in a straight ne and supported by courses of bricks; the chain was then laced on the coffers, and stretched with a weight of fifty-x pounds. The method adopted for bringing the marks enoting the two extremities of the measuring chain successively over the same point was this. In any position the ain was supported by a post at each end: that at the eceding end carried a pulley, over which passed the rope staining the weight which stretched the chain, while that the following end supported a screw apparatus, by means which the chain could be drawn back against the weight. nother post at each end, not connected with the former with the chain, supported a scale. Now, the chain be- g in one of its positions, the scale at the preceding end as moved by means of screws, until one of its divisions co- cided exactly with the mark on the handle of the chain. his scale remaining in its place, the chain was then car- ed forward into its next position, and adjusted by means its screw apparatus, until the mark on its following end incided exactly with that division of the scale with which e mark on the preceding end had coincided. After irty-eight chains had been measured, one of the chains as laid aside, on account of one of the links appearing to a little bent, and the remainder of the base measured with e other; the former, after the defect had been repaired, eing kept as a standard. Experiments were carefully made r determining the comparative lengths of the two chains, d also the rate of expansion; and in the actual measure- ent five thermometers were laid close by the chain in the ffers, and suffered to remain till they all indicated nearly e same temperature. The time required for this was in eneral from seven to fifteen minutes. The two chains were ain compared after the measurement, and it was found at the working chain had been lengthened, through the bbing and wearing of the joints, to the extent of 9·7 di- sions of the micrometer, corresponding to ·0373 of an ch. The whole base was divided into thirty hypothe- ses, but of unequal lengths, and each was reduced to the orizon by calculation. After the measurement was com- eted, the lengths of the steel chains were ascertained by amsden, by comparison with a 40-inch brass standard scale. ll reductions being made, the length of the base, by the ew measurement, at the standard temperature of 62° ut not reduced to the level of the sea), was found to be 7,404·3155 feet, being about $2\frac{3}{4}$ inches greater than was und from General Roy's measurement with the glass rods. e shall afterwards see, however, that the glass rods and eel chains were not referred to the same standard, and at there is consequently reason to suspect a considerably reater discrepancy. The mean of the two results, or 7,404·2 feet, was assumed as the true length of the base the future calculations.

---

[1] See Professor Playfair's Review of Mudge's Account of the Survey, in the Edinburgh Review, vol. v.

Of two operations which agree so closely in their results, can hardly be said that the one is in point of fact better any respect than the other. The practical difficulty in easurements of this kind, is to form correctly the contacts r coincidences of the extremities of two contiguous rods or hains; and in this respect the chain has unquestionably an dvantage, because, on account of its greater length, there re fewer coincidences to be made. Nevertheless, when it considered that the chain is not uniformly supported at very point, and that notwithstanding the weight by which is stretched, some doubt must remain whether all its points re in a straight line when brought into its position in the offers, and also the liability to irregular wear from the tretching, we are inclined to think, that a measurement by eans of rigid rods is to be preferred to one by a flexible hain.

After the measurement had been completed, the terminal oints of the base were permanently marked, by removing he wooden pipes and sinking iron guns into the ground, in such a position that the axis of the cylinder was placed exactly in the same vertical line with the terminal points. The muzzles were left above ground, and iron caps were screwed over them to protect the cylinders from the rain.

Triangulation in 1792.

In prosecuting the survey, it was resolved, in the first instance, to carry a series of triangles from the base southwards, for the purpose of determining some of the principal stations on the sea-coast, and also because this would afford an opportunity of connecting the series with the triangles of General Roy, and of thereby testing the accuracy of both operations. Another object of importance to general science, was to determine the length of a degree of longitude, by measuring the distance between Beachy Head on the coast of Sussex, and Dunnose in the Isle of Wight, two stations lying nearly east and west of each other, above sixty-four miles distant, and visible from each other in clear weather, so that they could be made the angular points of a large triangle. In the early part of the spring of 1792 the ground was examined, and the stations fixed upon; and the great theodolite having undergone some improvements by Mr Ramsden, and a moveable observatory having been erected for its reception, the triangulation was begun in the summer of that year. Most of the angles were observed more than once.

Signals.

When the stations were not more than about fifteen miles distant, staffs were erected for signals, in which case the angles were repeated till their truth became certain. For the more distant stations lamps and white lights were employed. In the use of the latter, it was not always possible to repeat the measures; but every precaution was taken to place the lights in the proper positions, and the charge and firing of them were committed to soldiers selected for their steadiness. The angle was taken when the light was going out. In order to preserve the exact positions of the points over which the axis of the instrument had been placed, large stones from a foot and a half to two feet square were sunk in the ground, generally two feet under the surface, having a hole of an inch square made in each of them, the centre of which marked the precise point of the station.

Meridians of Dunnose and Beach Head.

In the course of the summer of 1792, the instrument was carried to twelve different stations, commencing with Hanger Hill, and ending with Chanctonbury Ring, about six miles north-west of Shoreham. Early in the spring of the following year the operations were resumed; and the principal object of this year's business was to determine the directions of the meridians of Dunnose and Beachy Head, for the purpose of ascertaining the length of the degree of longitude. The method employed for obtaining the meridian, was that of observing with the theodolite the distance between a terrestrial object and the pole-star upon each side of the pole when the star is at its greatest elongation. This observation gives the double azimuth nearly, without any corrections for the star's apparent motion; and as the motion in azimuth when the star is near its greatest elongation is slow, the time was shown sufficiently near by a good pocket watch. In this manner the angle made by the arc of the great circle joining the two places with the direction of the meridian, was observed at both stations; and as the distance between the stations would become known from the triangulation, all the elements were obtained for determining the length of the degree of longitude on the terrestrial spheroid at that latitude. After the observations at those two places were concluded, the instrument was taken to a few stations in the neighbourhood of Salisbury, and the operations of the year terminated at Highclere.

Base on Salisbury Plain.

The greater part of the summer of 1794 was consumed in the measurement of a base of verification on Salisbury Plain. The measurement was effected in the same manner as at Hounslow Heath, one of the steel chains being used for measuring the different hypothenuses, and the other kept as a standard. The working chain was compared with the standard previous to the operation, and again when the measurement was finished. The details of the operation are entirely similar to those respecting the Hounslow Heath base; and the apparatus was different in no material respect. The base contained ninety-two hypothenuses, and the apparent length was 366 chains, minus 9·939 feet. The absolute length of the standard chain was assumed to be the same as it was found by Ramsden in 1791, by comparison with the standard scale; and after all the different reductions had been applied, the correct length of the base, at the temperature of 62° of Fahrenheit, and at the same level as the base on Hounslow Heath, was found to be 36,574·4 feet (nearly seven miles).

On computing the distance between the terminal points of this base, deduced from the Hounslow Heath base by different combinations of the triangles, the greatest and least results were found to be 36,574·8 and 36,573·8; the mean being 36,574·3 feet, or about one inch short of the measurement. So near an agreement must doubtless be ascribed, in part at least, to casual compensation of error; but it nevertheless affords a very satisfactory proof of the great accuracy with which the different parts of the work had been conducted.

Length of perpendicular degree.

The distance between Beachy Head and Dunnose, on which the determination of the length of a degree of the great circle perpendicular to the meridian was to depend, being computed from four different combinations of triangles, the mean of the four results was found = 339,397·6 feet, and the greatest difference from the mean was less than four feet. On computing from this, and the observed angles made by the straight line joining the two stations with the meridians at each, according to the method which will be subsequently explained, the length of a degree of the great circle perpendicular to the meridian at altitude 50° 41′ (nearly that of the middle point between Beachy Head and Dunnose), was found to be 61,182·3 fathoms, = 367,093·8 feet; and hence the degree of longitude at the two stations (which is found by multiplying the degree of the perpendicular circle by the cosine of the latitude) was obtained as follows: Beachy Head 232,312 feet, Dunnose 232,914 feet, the assumed latitudes being respectively 50° 44′ 24″ and 50° 37′ 7″. These results are respectively greater by about 772 feet than the corresponding degrees on the spheroid, which best represents the whole of the measured arcs of meridian, and of which the elements are given in FIGURE OF THE EARTH, p. 563.

In order to mark permanently the two important stations of Beachy Head and Dunnose, an iron gun was inserted in the ground at each of the places, having the diameter of the bore in the same vertical line with the point over which the axis of the instrument had been placed. Unfortunately this precaution did not prove sufficient; for when Captain Kater was about to remeasure the angles at Beachy Head in 1826, the gun was not to be found. "*In consequence of some misapprehension*, it had been removed along with some old guns which were formerly near that place, and thus one of the valuable parts of the survey of Great Britain was irrecoverably lost." (Phil. Trans. 1828, p. 154.)

The account of the survey for the years 1791–4 inclusive, in addition to the particulars now stated, gives also the latitudes and longitudes of a great number of places determined by intersections made from the principal stations, and referred to the meridian of Greenwich, or, if towards the western extremity of the series, to that of Dunnose. At all the principal stations the angles of elevation and depression were observed; and these observations being reciprocal, gave not only the relative altitudes of the stations, but also the mean refractions, assuming the spherical surface of the earth. With a view to obtain the absolute altitudes, the height of the station at Dunnose above low water was ascertained by levelling down to the sea-shore near Shanklin, a distance of about a mile. The mean refractions were found to vary from $\frac{1}{7}$th to $\frac{1}{15}$th of the contained arc. It was also noticed, that the relative heights deduced from elevations and depressions cannot always be depended upon (on account of the variable state of the refraction) to less than about ten feet, even supposing them to be the mean of two or three independent results, except, perhaps, reciprocal observations are made at the same instant of time. The observations from which the relative altitudes were deduced were made on cloudy days, or towards the evenings, when the tremulous motion of the air is commonly the least.

During the years 1795 and 1796, the triangulation was continued from the stations near the base on Salisbury Plain, along the coasts of Dorsetshire, Devonshire, and Cornwall, to the Land's End, as it was considered desirable to have an early determination of the latitudes and longitudes of the great headlands in the channel, and also of the Scilly Isles. The details of the operations, including the calculations of the side of the principal triangles, the heights of the stations, the mean refractions, the distances of a great number of intersected objects from the principal stations, are given in the Philosophical Transactions for 1797, and form the last part of the first volume of the Trigonometrical Survey. The same paper also contains the bearings and distances from the meridian and parallels, and also the latitudes and longitudes of a number of places observed in Kent in 1795, with a smaller theodolite (half the size of the principal one), for the purpose of completing the map of that county.

The next account of the operations connected with the Ordnance survey is contained in the Philosophical Transactions for 1800, and is given in the name of Captain William Mudge alone, Mr Dalby having now retired from the service. This account describes the operations in 1797, 1798, and 1799, and is divided into three sections, of which the first contains the calculations of the sides of the principal and secondary triangles extended over the country in those three years, together with an account of the measurement of a new base line on Sedgmoor. The second section contains the computed latitudes and longitudes of those places on the western coast which had been intersected in 1795 and 1796, and also of such other places as were found conveniently situated in respect of three new meridians, the determination of which forms part of the present account. The last section contains the triangles which were carried over Essex, the western parts of Kent, and portions of the counties adjoining Kent, Suffolk, and Hertfordshire.

With respect to the determination of meridians, just alluded to, it is to be observed, that by reason of the curvature of the earth, and the errors consequently arising from computing on the supposition that the earth is a plane, it becomes necessary that the direction of the meridian be determined anew where the operations are extended over distances of about sixty miles in an eastern or western direction. The distance from Dover to Land's End is somewhat about 300 miles, and between these places five intermediate meridians were observed, dividing the distance into six nearly equal parts. These were Beachy Head and Dunnose (already mentioned), Black Down in Dorsetshire, Butterton Hill in Devonshire, and St Agnes Beacon in Cornwall. In computing the longitudes and latitudes, the places were of course referred to the nearest of those meridians; and a place in the middle between two was referred to both, and the mean of the results taken.

The operations of 1797 commenced with the observation of the pole-star at Black Down, early in April; and in the course of the summer the great theodolite was taken to twenty-one other stations, at which the angles were determined, all included between the meridian of that station and St Agnes Beacon. It was judged inexpedient to carry the operations from this point into the north of Devonshire until a new base had been measured, the triangles at present being dependent upon those made in Cornwall in the previous year.

In 1798 a series of secondary triangles was observed for completing the survey of Kent and Essex; but the principal operation of this year consisted in the measurement of a new base of verification on King's Sedgmoor in Somersetshire. This new measurement was conducted in the same manner, generally, as those of the former bases; but on account of the irregularity of the ground, which was cut up in all directions by numerous ditches and large drains, it was thought expedient to have a new chain of fifty feet; and accordingly one was prepared by Ramsden, similar in construction to the two 100 feet chains used at Hounslow Heath and Salisbury Plain. This new chain was not used for the whole of the measurement, but only in a few cases when the handles of the 100 feet chain would have had their places over ditches, or in situations in which there would not have been the means of correctly placing the register heads under the handles. The measuring chains were compared with the standard, not before the measurement commenced, but after it had considerably advanced, and again at the end of the operation; and it was assumed that the length of the standard chain had remained unaltered since its last determination by Ramsden. The reduced length of the base was 27,680 feet, or nearly 5¼ miles; and it was supposed by General Mudge that the error cannot exceed nine inches.

The next account which we have of the survey is contained in a paper which was read before the Royal Society in June 1804, entitled "An Account of the Measurement of an Arc of the Meridian, extending from Dunnose in the Isle of Wight, to Clifton in Yorkshire, by Major W. Mudge." This forms part of the second volume of the Survey. The measurement of an arc of the meridian was contemplated from the commencement of the survey, but had been delayed for some years on account of the zenith sector, with which the celestial arc was to be determined, not having been completed by Mr Ramsden, whose health was then declining, and who in fact died before the instrument was entirely finished.

For the purpose of determining the figure and dimensions of the earth by the measurement of meridional arcs, it is important that the arc be of considerable length, in order to diminish the influence of any error in the determination of the difference of the latitudes of its extreme points. On looking at the map of Great Britain, it will be seen that the longest meridional line contained in it, is one which passes from Lyme in Dorsetshire, northward into Scotland, and terminates at Aberdeen, comprehending an arc of nearly 4° 47′. This line, therefore, presented itself as the most eligible; but, on a closer examination, it was found that the arc would run through a country abounding in hills of considerable magnitude, and consequently that no advantage would probably be gained from observing the zenith distances of stars at any of the intermediate stations, on account of the irregular local attraction. General Mudge therefore selected the meridional line passing from Dunnose to the mouth of the Tees, as being the freest from apparent obstructions, and of sufficient length. The choice of Dunnose as the terminal station likewise presented a considerable advantage; for that station having been connected with the Royal Observatory by the previous operations, the astronomical observations made there would serve to correct the latitudes of the places formerly determined. The point selected for the northern extremity was Clifton, a small village in the vicinity of Doncaster, nearly on the meridian of Dunnose; and a level of sufficient extent for the measurement of a base of verification was found at Misterton Carr, in the northern part of Lincolnshire. The two extreme stations were connected by a chain of twenty-two triangles, lying nearly in the direction of the line to be measured. Of these triangles, eleven, extending from Dunnose to Arbury Hill, near the middle of the line, had been already observed, and their sides computed from the Hounslow Heath base. The angles of the remaining eleven were observed in the years 1801 and 1802, and the distances computed from the new base.

New base on Misterton Carr.

The base on Misterton Carr was measured in the summer of 1802, by the same apparatus, and exactly according to the same methods as had been employed in the three former bases, on Hounslow Heath, Salisbury Plain, and Sedgmoor. Previously to the commencement of the operations, the measuring chains (the hundred feet and fifty feet) were both compared with the standard chain; and a similar comparison was made after the work was completed. It was assumed that the length of the standard chain was the same as when it had been compared by Mr Ramsden; an assumption which was subsequently proved to be correct (within very small limits) by a new comparison of the standard chain with Ramsden's brass scale. The extremities of the base were marked by two large blocks of oak sunk into the ground, having each a square hole in its upper surface, into which lead was cast, and ground to a smooth plane; and the diagonals of the holes being drawn on the lead, the intersections of the diagonals formed the terminal points. After making the necessary reductions for temperature, the wear of the chains, &c. the true length of the base at temperature 62° was found = 26,342·7 feet. No reduction was made for height above the sea, the altitude of the ground on which the base was horizontally measured being only thirty-five feet above the surface of the sea in the mouth of the Humber at *half tide*. As the correct determination of this base was of great importance, every precaution was taken in the course of the operations, and General Mudge was of opinion that the error of the measurement in excess or defect could not exceed two inches.

On computing the first eleven triangles, beginning at Dunnose, the distance between the stations at Corley and Arbury Hill, near the middle of the arc, was found to be 117,463 feet; and this depended on the bases on Hounslow Heath and Salisbury Plain. On computing directly from the measured base at Misterton Carr, the remaining eleven triangles, the same distance between Corley and Arbury Hill was found to be 117,457·1 feet. The difference, therefore, falls short of six feet; but this cannot be regarded as great, when it is considered that the distance between the two stations is rather more than twenty-two miles, and that the whole line from Dunnose to Clifton is nearly 200 miles. Had the computation been carried on from Dunnose all the way to Clifton, the length of the base on Misterton Carr, deduced from those of Hounslow Heath and Salisbury Plain, would have been found to be about one foot greater than its measured length.

Method of computing the arc of meridian.

The whole terrestrial distance between the parallels of the two stations was computed by the method of parallels and perpendiculars, with reference to the meridians of both the extreme stations. The bearings of certain sides of the triangles from the meridian of Dunnose were deduced from the observed angles; and the sides being respectively multiplied into the cosines of the bearings, gave the distances on the meridian; the sum of which distances, of course, was the length of the meridional arc, or rather the sum of the twenty-two chords deduced from the sides of the triangles. This method proceeds on the supposition of the earth's surface, to some distance on both sides of the line, being plane; but as the triangles ran nearly north and south, and most of them were intersected by the meridian, and, moreover, as the distance between the meridians of the two extreme stations was only a few feet, the supposition leads to no sensible error. General Mudge states that he took the trouble to calculate the length of the whole line, by increasing each portion computed from the sides of the triangles by the difference between the chord and its arc, and that the result only exceeded the former computation by about two and a half feet.

The whole length of the arc, from Dunnose to the parallel of Clifton, was found to be 1,036,337 feet; from Dunnose to the point over which the sector was placed at Arbury Hill, 586,319·5 feet; and, consequently, from the parallel of Arbury Hill to that of Clifton, 450,017·5 feet.

Determination of the celestial arc.

The geodetical part of the operation being completed, it still remained to determine the amplitude of the celestial arc. The instrument employed for the purpose was a zenith sector, contrived and executed in greater part by Ramsden. A description of this superb instrument would here be out of place; but it may be proper to state the general principle of its construction. The object being to measure the zenith distances of stars which pass near the zenith (in order to diminish the effects of refraction), the sector is constructed by suspending a telescope nearly vertical, and in such a manner that its axis shall have a motion in a vertical plane, extending to only a few degrees on each side of the vertical. From the axis of motion, which is placed very near the top of the telescope, a plummet is suspended by a very fine wire; and on the lower end of the telescope a scale is placed in the plane of the motion, and directly before the plummet. Now, it will be obvious, that as the telescope carries the scale along with it when it is moved in the vertical plane, while the plummet remains at rest, the angular deviation of the axis of the telescope from the vertical will be measured on the scale. It is necessary that the instrument be capable of being turned half round in azimuth, for the sake of reversion. When in use, the plane of the sector is placed in the meridian at one extremity of the arc, and the zenith distances of some stars at their meridian passage observed. It is then transported to the other extremity, and the zenith distances of the same stars are there also observed; and the mean difference of these distances is the amplitude of the arc, which is by this means obtained immediately and independently of the latitudes of the stations or declinations of the stars. The telescope of the sector in question was nearly eight feet long, and had an object-glass of four inches in diameter.

The sector, after some preliminary examination at the Tower, was first set up at the Royal Observatory, for the purpose of observing the zenith distances of some stars to be afterwards observed at Dunnose, in order to determine the latitude of that station. It was then, in the spring of 1802, removed to Dunnose, where it was set up, at a distance of about six and a half feet from the station where the azimuth had been observed in 1791. The whole number of stars observed was twenty-seven; and a sufficient number of observations having been obtained by the end of June, the sector was then transported to Clifton, where seventeen of the same stars were observed. Subsequently, in the same year, the instrument was set up at the station at Arbury Hill, which is very nearly at the middle of the arc, and where twelve of the stars which had been seen at Clifton were observed. In October the party returned to London, and it was found, on examination, that the sector was in as perfect a state as when first sent into the field, so that no error was to be apprehended from derangement or injury during transportation to the different stations.

On computing the observations, the final results were found to be as follows (Measurement of an Arc of Meridian, Trigonometrical Survey, vol. ii. p. 107):

Mean amplitude of the celestial arc between Dunnose and Clifton	2° 50′ 23″·38
.... between Dunnose and Arbury Hill	1 36 19 ·98
.... between Dunnose and Greenwich	0 51 31 ·39

For the deductions from those amplitudes combined with the above geodetical measures relative to the degree of the meridian, we refer to the article FIGURE OF THE EARTH, p. 562. It is however to be remarked, that since the publication of that article, a paper by the celebrated astronomer Bessel has appeared in the *Astronomische Nachrichten* (vol. xiv. No. 336), in which an error is pointed out in the determination of the celestial arc. It appears that one of the stars (α Aurigæ), observed at all the stations, was incorrectly reduced to the beginning of 1802; and that the error (which probably arose from applying the correction for nutation with a wrong sign) amounted to 18″. On correcting this error, and deducing the mean result by a more exact method of reduction, Bessel finds the amplitudes to be respectively as under:

Dunnose to Clifton	2° 50′ 23″·497
.... to Arbury Hill	1 36 20 ·398
.... to Greenwich	0 51 31 ·667

Adopting the above amplitudes as corrected by Bessel, and assuming (according to the measurement) the distance between Dunnose and Clifton to be 1,036,337 feet, the length of a degree of the meridian at the latitude of the middle point (52° 2′ 20″) will be found = 364,925·25 feet, or 60,820·88 fathoms of the scale to which all the measures given in the survey are referred. General Mudge states this distance to be 60,820 fathoms. The length of the degree at the middle point of the arc between Dunnose and Arbury Hill being found in like manner, gave 60,864 fathoms, exceeding the above by forty-four fathoms. But as this latitude is farther to the south, the length of the degree ought, on the supposition of the earth's compression, to be less by about nine or ten fathoms. This anomaly, presented by the measurement, is usually ascribed to a deflection of the plumb-line of the sector, occasioned by local attraction.

The third volume of the Trigonometrical Survey appeared in 1811, under the joint names of Colonel Mudge and Captain Colby. It contains an account of the progress of the survey from 1800 to 1809 inclusive, and, when taken in connection with the accounts previously published, comprises the survey of almost all England, the south of Wales, and a part of Scotland. The volume embraces a great variety of interesting topographical matter. It gives the angles observed with the great theodolite at the principal stations; the calculation of the sides of the triangles, amounting in number to 281; the elevations and depressions of the stations, as seen from each other; a description of the situation of the stations; an account of the measurement of a new base on Rhuddlan Marsh, near St Asaph, in North Wales; and the prolongation of the arc of meridian from Clifton northward to Burleigh Moor in Yorkshire. It likewise contains the computed altitudes of the stations, and of many other remarkable hills, and also the latitudes and longitudes of all the principal places in the country.

The base on Rhuddlan Marsh was measured in October 1806, with the apparatus so often referred to in the preceding statement. After the necessary reductions were applied, its true length at temperature 62° was found to be 24,514·26 feet. The ground was a flat about four miles north-west of St Asaph, and its mean height above low-water mark being only twenty-five feet, no reduction was requisite for height above the sea. In proof of the agreement between the present and the former measurements, the following instances are given. Computing from the base on Misterton Carr, the distance between Castle Ring and Weaver Hill (two stations in Staffordshire) was found to be 111,144·1 feet; the same distance deduced from the triangulation proceeding from the new base in Rhuddlan Marsh was 111,148·4; whence the difference between the two results in a line exceeding twenty-one miles is only 4·3 feet. Again, the distance from May Hill to the station on Malvern Hills, depending on the Hounslow Heath base, was found = 82,260 feet; the same distance, found by computing from the Rhuddlan Marsh base, was 82,251·1 feet; the difference being thus 8·9 feet. From this base several series of triangles were carried in different directions. One series extended to Anglesea, and thence by Snowdown, down the western coast of Wales, joining, near Aberystwith, a series proceeding from the triangles formerly observed in Gloucestershire. A second series proceeded southward from the base, and joined the southern triangles in Glamorganshire. A third series branched out towards the east, and united with those proceeding westward from the base on Misterton Carr; and a fourth series was carried from the Rhuddlan Marsh base, through Lancashire, Westmoreland, and Cumberland, into Scotland, and connected with another series extending from the Misterton Carr base, through Yorkshire and Northumberland, and the east part of Scotland, as far as the north side of the Frith of Forth.

In the different series of triangles now mentioned, the third angle of the triangle was not observed in many instances, the peculiar character of the country rendering it impracticable, or at least very difficult, to carry the large theodolite to the station. It is stated in the preface to the volume, that "with an instrument so excellent as that used in the survey, except for the purpose of intersecting surrounding objects, it is perhaps not necessary to adhere tenaciously to the practice of observing the third angle of every triangle." Notwithstanding this opinion, we think it is much to be regretted that the important verification obtained from the observation of the third angle should have been dispensed with on any account whatever; and in fact the observation of many of those very angles, and a consequent recomputation of the sides, have since been found necessary, in order to reconcile the results.

One of the most interesting portions of the volume is the account of the extension of the arc of meridian northward from Clifton to Burleigh Moor, a place situated about three miles north from the town of Gisborough in Yorkshire. In July 1806, the sector was erected at this station, and the zenith distances of several stars observed. The observations were reduced to the first of January 1806, and those formerly made at Dunnose having been reduced to the same epoch, the mean of the whole gave the difference of latitude between the parallels of Dunnose and Burleigh Moor = 3° 57′ 13″·1. The terrestrial distance between the parallels of the two places was calculated both on the meridian of the station at Burleigh Moor and on that of Dunnose, and the mean of the two results was found = 1,442,852·5 feet. This determination agrees very closely with the former determination of the arc between Dunnose and Clifton; for it has been stated that, in respect of that arc, the terrestrial distance was 1,036,337 feet, and the amplitude of the corresponding arc in the heavens = 2° 50′ 23″·38; and assuming the length of the arc to be proportional to its amplitude (which is not sensibly erroneous for an arc of three or four degrees), the difference of the latitudes of Dunnose and Burleigh Moor will be found by a simple proportion = 3° 57′ 13″·6. But the difference of the latitudes, as determined by the sector observations, was 3° 57′ 13″·1, and therefore disagreeing only to the extent of half a second, or about fifty feet on the ground. The resulting length of the meridional degree at the mean latitude is 364,943 feet.

Another determination of the length of a meridional degree was obtained by erecting the sector at the station of Delamere Forest, in Cheshire, about five miles north of Tarporley. Eight of the stars which had been observed at Dunnose were observed at this station; and the mean of the observations gave 2° 36′ 12″·2 as the difference in latitude between the stations on Dunnose and Delamere Forest. The direction of the meridian was likewise observed at this station, and the bearing of one side of a triangle thereby determined; which being carried through the series of triangles connecting Delamere Forest with Black Down in Dorsetshire, the distance between the parallels of Dunnose and Delamere Forest was found = 925,188·5 feet. By carrying on the calculation through the same series of triangles, but with an azimuth determined at a different station, the distance between the parallels was obtained = 925,180·7 feet. The mean is 925,184·6 feet. Now if we seek an arc having the same proportion to the arc between Dunnose and Burleigh Moor which the distance between those stations has to this distance, we shall find 2° 36′ 13″·2 for the amplitude. But the amplitude derived from the sector observations is 2° 36′ 12″·2. Hence the difference between the observed and computed amplitude is only 1″, which corresponds to an error of 0″·4 in one degree. The agreement may be considered as satisfactory; but by reason of the distance of Dunnose from the meridian of Delamere, this determination of the length of the meridional arc cannot be admitted as of equal certainty with that of the meridian of Burleigh Moor, in any deductions relative to the figure of the earth. The result, however, gives 60,823 fathoms, or 364,938 feet, for the length of a meridional degree in latitude 53° 34′, or nearly the centre of England.

It would far exceed our limits to give a detailed description of the immense mass of observations and results contained in this volume, and it is beside our purpose to enter into any critical examination of its contents. In a work of such magnitude, and abounding with such a multiplicity of minute details, it will not be expected that errors can be entirely avoided; and a considerable number, it must be admitted, have found their way into the volume. In some respects, also, the deductions have not been made so as to furnish results possessing all the accuracy possible to be attained by means of the improved science of the present day; but it is to be observed, that many of the more refined methods of calculation have been introduced into the practice of geodesy since the volume was published. The method of assigning weights to the several results, of estimating the probable errors, and applying corrections according to an uniform fixed rule derived from the theory of chances, and thereby avoiding arbitrary adjustments, was then scarcely known. It is due, however, to the present able and enlightened superintendent of the survey to state, that all these less perfect methods of computation and reduction have long been abandoned, and that every advantage which can be derived from the refined theories of Gauss and Bessel has been brought to bear on the work; and we have little doubt, that when the next account of it shall appear, the scientific skill displayed in the reductions will be found to be quite on a par with the instrumental precision.

The preceding abstract brings down the history of the survey to the end of the year 1809, and we regret that our account must here be brought to a conclusion; for although the work has continued to be prosecuted with more or less intermission since that time, no further detailed account has been given to the public. It may not be without interest, however, to state generally a few particulars respecting its subsequent progress.

Continuation of the survey.

Since 1809, the prosecution of the survey has been placed under the able direction of Colonel Colby of the Royal Engineers. The triangulation which had been carried to the south-east part of Scotland, as far as the Frith of Forth, was first continued along the east coast to the borders of Ross-shire, and subsequently extended to the Shetland Islands. A series was also carried from the Cumberland triangles, along the western coast, through Dumfriesshire, and to the summit of Ben Lomond, connecting all the remarkable points in Perthshire. In 1817 a base of verification was measured with the steel chains by Colonel Colby, on Belhelvie Links, near Aberdeen. Shortly after this, the survey of Scotland was interrupted for a number of years, and the scene of operations transferred to Ireland, an accurate survey of that country being considered, from political reasons, as of more urgent importance.

Survey of Ireland.

The Ordnance survey of Ireland is perhaps the most complete operation of the kind that has ever been executed in any country. Hitherto the different bases of verification had all been measured with the same apparatus, and according to the same methods, as were used on Hounslow Heath; but doubts having arisen respecting the accuracy attainable by means of the steel chains, Colonel Colby, on entering upon this new field, resolved to have recourse to an entirely different method of proceeding, and, instead of chains, to adopt the ingenious compensating apparatus which has been described in FIGURE OF THE EARTH, p. 553. By this method, metallic bars of ten feet in length, and defined by points whose distance remains invariable in all temperatures, are placed accurately along the line to be measured; and the distance between the terminal points of the preceding and following bars is measured by a micrometer microscope, with a certainty altogether unattainable by measuring rods abutting against each other, or by observing the coincidence of straight lines on the handles of the steel chains. The ground selected for the base lies on the east shore of Lough Foyle, on the north coast of Ireland, and the line itself forms part of a straight line drawn from Shaw Mountain to Mount Sandy, nearly north and south. The whole line measured was nearly eight miles in length. For a verification, it was divided into two parts, one about half the length of the other, and the length of the one deduced from the other in various ways by triangulation. By this means it was estimated that the greatest possible error could not exceed two inches. It was also prolonged by triangulation from the north end to Mount Sandy, whereby two additional miles were given to it, so that it may be considered as a base of ten miles, the probable accuracy of the last part being quite as great as that of the part determined by the actual application of the measuring bars. From this base a series of triangles commenced, which proceeded all over the island, and were connected with those formerly observed in Wales, the Isle of Man, the west coast of Scotland, and the Hebrides. Some of these triangles were of enormous extent, the sides exceeding a hundred miles.

The survey of Ireland having been completed, at least so far as regards the primary triangles, that of Scotland was recommenced in 1838, and has already been carried from the eastern counties westward to the island of Lewis in the north. At the present time (1840), surveying parties are also employed at different places in Wales and the north of England, in observing the angles which had formerly been omitted, and verifying others which had not been satisfactorily observed.

Ordnance Maps.

We cannot conclude this brief and imperfect sketch without alluding to the admirable maps which have been published from time to time, and are now in progress. These are all designed from the materials collected in the field, and are not only drawn, but also engraved and printed, at the Ordnance Map Offices in the Tower, and at Dublin. Of the maps of England, thirty-eight counties, embracing all the southern part of the island, have now been published, engraved on a scale of one inch to the mile. The maps of Ireland, of which eighteen counties are published, are given on the magnificent scale of six inches to the mile, and not only exhibit, with the utmost distinctness, the natural features of the country, but even the minutest topographical details. This series of maps forms a splendid national work; and as no part of the map of Scotland has yet been engraved, we trust that the whole of that country will be given on the same scale.[1]

Of the Standards of Length used in the Trigonometrical Survey.

In the British survey, all the linear measures are expressed in feet measured from a certain scale; and in order that the results relative to the dimensions and figure of the earth may be comparable with those of other similar operations, it is necessary to determine the relation of this unit to other known measures.

General Roy's measurement of the Hounslow Heath base was performed with glass rods, on which lengths of twenty feet had been set off by Ramsden, from a standard scale, which is described "as a finely divided brass scale of the length of forty-two inches, with a Vernier's division of 100 at one end and one of fifty at the other, whereby the thousandth part of an inch is perceptible. It was originally the property of Mr Graham, the celebrated watchmaker; has the name of Jonathan Sisson engraved on it, but was known to be divided by Bird." From this scale the measure was transferred to the glass rods as follows. A deal plank upwards of thirty feet long, nine or ten inches broad, and about three inches thick, was set up edgewise on stands, and planed perfectly straight and smooth. A silver wire was then stretched along the middle of the edge from one end to the other, and six distances of forty inches each were marked off by the side of the wire, at which points brass pins were driven into the wood, and their tops polished. A fine dot being then made on one of the extreme pins, and the silver wire being stretched over the dot and the middle of the other pins, the extent of forty inches was, with the utmost care, taken from the scale, by means of a pair of beam-compasses, whose micrometer screw shewed very perceptibly a motion of the 5000th part of an inch, and transferred to the following brass pin on the plank. In this manner all the six lengths were laid off. Two brass rectangular cheeks were then placed on the plank so as to bisect the two extreme dots, and present relatively to each other surfaces perfectly parallel. The glass rods were then placed between the cheeks, and the bell-metal buttons which formed their extremities ground down until the length (determined by the coincidence of a fine line on the glass rod with another on the moveable apparatus on the extremity of the rod) was accurately fitted between the cheeks, and was consequently twenty feet of the brass scale.

The scale which it has been usual of late years to adopt in works of science as the standard of English measure, goes by the name of Sir George Shuckburgh's scale, and is described at length in the Phil. Trans. for 1798. The relation between this scale and several other standards was investigated by Captain Kater, whose experiments and results are given in the Phil. Trans. for 1821. From these experiments it was found that thirty-six inches of General Roy's scale are equal to 36·000930 inches of Sir George Shuckburgh's; whence, in order to reduce distances expressed in terms of General Roy's scale to Sir George Shuckburgh's, we must multiply by ·9999742.

Now it has been stated that the length of the Hounslow Heath base, as measured by the glass rods, was found to be 27404·08 feet. Using the above multiplier, the same distance expressed in terms of Shuckburgh's scale is 27403·38 feet.

---

[1] From the "Estimates of the Office of Ordnance" for the year 1840-41, printed by order of the House of Commons, it appears that the sums of money already granted for the surveys of England, Wales, and Scotland, amount to L.326,163, and that the sum proposed to be taken in the present year is L.18,400. On the survey of Ireland there has been expended the large sum of L.619,520, including L.60,000 for the services of the present year. The number of persons employed on the Irish survey, at the date of the estimates, is stated to be 2037; and the number employed on the British survey 82.

gono-
rical
vey.

In the Ordnance survey, all the bases, excepting the re-ent one in Ireland, were measured with a steel chain, which was compared from time to time, generally before ind after the operation, with a similar steel chain of 100 eet, which was not otherwise used in the measurement. Γhe primary measure in this case was a brass standard orty-inch scale, belonging to Mr Ramsden, and not Ge-ieral Roy's. From this standard, six lengths of forty nches were transferred, by means of the beam-compass, to prismatic bar of cast iron, into which brass points were nserted at the proper distances, so that the bar formed a neasure of twenty feet. In order to transfer this to the teel chain, a portion of the chain was placed on rollers xactly parallel to the iron bar, and stretched, as in the neasurement of the several bases, with a weight of fifty-six ounds. From the extreme points on the edge of the bar, narking the distance of twenty feet, fine wire plummets vere suspended, so as nearly to touch the chain. One end f the chain, determined by a fine line drawn on the brass andle, being then brought under the wire by means of an djusting screw, a point coinciding with the other wire was nade in the chain. This part of the chain was then shift-d, and another twenty feet measured in the same manner; nd thus the whole chain was determined at five successive perations.

sden's
ard

The brass scale which was used in this operation is sup-osed to be lost, but the prismatic bar is still in existence, nd forms, therefore, the only authentic standard of the sur-ey, the standard steel chain being probably liable to some lteration from rust or wear at the joints. This bar was so examined by Captain Kater, who found the mean yard n it to be equal to 36·00254 inches of Shuckburgh's scale. ssuming this determination to be correct, it follows that very distance given in the Ordnance survey, in order to be xpressed in terms of Shuckburgh's scale, must be multi-lied by ·9999694. Now the Hounslow Heath base was und by the measurement with the steel chains to be 7,404·3165 feet of Ramsden's standard scale. The length, herefore, in terms of Sir George Shuckburgh's scale, is 7,402·38 feet.

ri-
the
ea-

It thus appears that the two measurements of this im-ortant base, when reduced to the same standard, give the llowing results:

with the glass rods................27,403·38 feet,
with the steel chain...............27,402·38 feet.

he difference is one foot, which is larger than can well be nsidered probable, supposing the steel measuring chain have been exactly five times the length of each of the lass rods. In the account of the survey, the difference is ated to be 2¾ inches; but this was on the supposition hat the two standards were precisely of the same length.

Prior to Captain Kater's experiments, it had been assumed, om some comparisons with an intermediate scale belong-g to the Royal Society, that Ramsden's scale exactly greed with General Roy's. The latter states (Trigono-etrical Survey, vol. i. p. 16), that he placed the two ales (his own and the Society's) together on a table with hermometers alongside, and that after they had remained this position two days, Mr Ramsden carefully took a ngth of three feet from the Royal Society's standard ith his beam-compasses, and applied it to the other scale, nd it was found to reach *exactly* to thirty-six inches, the mperature being 65°. In like manner, when the length of the steel chains was determined, Mr Ramsden compared his own brass standard with that of the Royal Society, "and after the two standards had been allowed to remain together about twenty-four hours, they were found to be *precisely* of the same length." The temperature is not stated. Now this perfect agreement leads to the inference that the comparisons were not made with the requisite care, or that the means employed were insufficient.[1] In fact, it was found by Captain Kater, that the difference between General Roy's scale and that of the Royal Society amounted to ·00047 of an inch; a quantity, however, within the limits of the distance measurable with the beam-compasses. The principal cause of the difference between the two determinations of the base may probably be ascribed to errors committed in transferring the length of the scale to the twenty-feet iron prism; and perhaps also in part to an erroneous comparison of this rod with Shuckburgh's scale; for it is said that the points on the brass pins inserted in the rod are so worn and enlarged by the application of the beam-compass as to render any exact comparison impossible.

Trigonometrical Survey.

The standard measure of the Irish base is a distance of ten feet, defined by two fine points on a bar of cast iron. We are not acquainted with the length of the mean foot in terms of Shuckburgh's scale; but as none of the results yet published are given in terms of this base, its accurate length, in relation to other standards, is at present unimportant.[2]

Of the Selection of the Stations and the Signals.

In conducting a survey over an extensive country, the choice of stations must in a great measure be determined by the nature of the ground; for it is obvious that signals can only be erected at places mutually visible from each other. But although the natural irregularities of the surface of the ground render an entirely arbitrary disposition of the signals impracticable, there will frequently be room for a choice between two or more points; and it is therefore important to determine the conditions which must be fulfilled, in order that the inevitable errors of observation may have the least effect on the measured distances.

Effect of a small error of observation.

Let A, B, C be the three angles of a triangle, and a, b, c the sides respectively opposite. In each case the data are the three angles, and one of the sides, as a; and the elements to be calculated are b and c, the remaining sides. The question therefore is to determine the species of triangle, in order that the computed lengths of b and c may be the least affected by small indeterminate errors in the measurement of the angles. Suppose each of the angles to have been observed, and let the errors of observation be respectively α, β, γ. When the sum of the observed angles differs from 180°, or rather from 180° + the spherical excess, each angle is corrected by applying to it one third of the excess or defect. After the angles have thus been corrected, they still remain affected with the errors of observation; but as the sum is now correct, it is plain that the sum of the errors is nothing, or that $\alpha + \beta + \gamma = 0$, and consequently $\alpha = -(\beta + \gamma)$. Now, putting the given side $a = 1$, the side c is found in parts of a from the formula $c = \frac{\sin. (C + \gamma)}{\sin. (A + \alpha)} = \frac{\sin. C \cos. \gamma + \cos. C \sin. \gamma}{\sin. A \cos. \alpha + \cos. A \sin. \alpha}$; and since α and γ are very small angles, we may assume cos. $\alpha = 1$, sin. $\alpha = \alpha$, cos. $\gamma = 1$, sin. $\gamma = \gamma$, by which the formula becomes, on substituting $-(\beta + \gamma)$ for α,

---

[1] On this subject, see an excellent paper by Mr Baily in the ninth volume of the Memoirs of the Royal Astronomical Society.

[2] In the article Figure of the Earth, the lengths of the English arcs of meridian are copied from the Trig. Survey, and are conse-ently expressed in feet of Ramsden's standard scale, while all the foreign measurements, as well as those of the Indian arcs, are in feet of huckburgh's scale reduced according to the comparative values of the different standards given by Captain Kater. This inadvertence does ot affect the values there given of the earth's axes, and the lengths of the equatorial and meridional degrees, all of which are understood to e expressed in feet of Shuckburgh's scale.

$$c = \frac{\sin. \mathrm{C} + \gamma \cos. \mathrm{C}}{\sin. \mathrm{A} - (\beta + \gamma) \cos. \mathrm{A}}.$$

Dividing the numerator of this expression by the denominator, and rejecting the terms in the quotient which contain the squares and higher powers of β and γ, we get

$$c = \frac{\sin. \mathrm{C}}{\sin. \mathrm{A}} + \frac{\beta \cos. \mathrm{A} \sin. \mathrm{C}}{\sin.^2 \mathrm{A}} + \frac{\gamma \sin. \mathrm{B}}{\sin.^2 \mathrm{A}},$$

so that the error of the side c is

$$\frac{\beta \cos. \mathrm{A} \sin. \mathrm{C}}{\sin.^2 \mathrm{A}} + \frac{\gamma \sin. \mathrm{B}}{\sin.^2 \mathrm{A}}.$$

Similarly, the error of the side b is found to be

$$\frac{\gamma \cos. \mathrm{A} \sin. \mathrm{B}}{\sin.^2 \mathrm{A}} + \frac{\beta \sin. \mathrm{C}}{\sin.^2 \mathrm{A}}.$$

It now remains to determine the conditions under which these expressions have the smallest values. Since $\alpha + \beta + \gamma = 0$, in every case two of these quantities must have the same sign, and the third the opposite. If therefore α and β are both positive, γ is negative; and if they are both negative, γ is positive; so that as γ must of necessity be either positive or negative, there are only two chances for α and β having the same sign. In like manner, there are also two chances only for α and γ having the same sign and β the opposite, and for β and γ having both the same sign and α the opposite. It thus appears, that for any two specified errors, there are only two chances for both having the same sign, and four chances for their having opposite signs; so that in the above expressions the probability that β and γ are of opposite signs, is twice as great as the probability of both having the same sign. Now if they have opposite signs, both expressions will be diminished if cos. A be positive, that is, if the third angle A be less than 90°, or less than a right angle. With respect to the relation between B and C, which gives the smallest chances of error, it may be assumed as probable that the two errors β and γ, though they have opposite signs, will not differ greatly in magnitude. But if they are nearly equal, the two expressions for the errors of b and c will have the smallest values when B and C are nearly equal. Hence the conditions which afford the greatest probability of the smallest errors are these: 1. That the angle opposite to the measured side be less than a right angle; and, 2. that the angles adjacent to that side be nearly equal. These conditions will be best fulfilled on the average of a series, by making the triangles as nearly as possible equilateral.

If only two angles B and C have been observed, then there is the same probability of β and γ having the same sign or opposite signs. In this case the chance of smallest error is obtained by making cos. A = 0, that is, when A is a right angle.

Description of signals.

In the earlier part of the British survey, the signals made use of were of various kinds, but principally flag-staffs carrying reverberatory lamps, and furnished with concave copper reflectors about nine or ten inches in diameter, well polished and silvered, and enclosed in tin cases, having plates of ground glass in front, to prevent the bad effects of unequal and unsteady light from exposure to the wind. Such signals can be seen at the distance of twenty or twenty-four miles. For more distant stations, Bengal or white lights were fixed in small sockets, supported on a tripod of about five or six feet in height. By means of a plummet, these could be readily placed precisely over the point marking the station. The now well-known Drummond light (for the description of which see Mr Drummond's paper in the Phil. Trans. for 1826) was practically applied as a night-signal at some of the stations in Ireland, and the west of Scotland. But the difficulties and inconveniences of night-signals are so great, and the observations attended with so much uncertainty from the unsteadiness and scintillation of the light, that the practice of observing by night has of late years been abandoned. At present the signals are usually formed by building a conical pile of stones, in some instances exceeding twenty feet in diameter at the base, over the point which marks the centre of the station. Such signals are of course subject to this great inconvenience, that they can only be seen in favourable states of the atmosphere; but in all other respects they are found preferable to any others. In some of the late operations where the distances were not very great, a plate of metal was used, having a narrow vertical slit cut in it; and in this case the signal consists of the line of light passing through the slit, and which can be rendered more brilliant by means of reflectors suitably disposed. Colonel Colby has also on some occasions successfully employed the *heliotrope*; a method recommended by Gauss, and which consists in throwing a beam of solar light upon a distant station by reflexion from a small plane mirror, as that of a sextant or reflecting circle. A description of this ingenious but not very convenient method of forming signals for geodetical purposes is given in Zach's *Correspondance Astronomique*, vol. v. p. 374.

Of the Calculation of the Sides of the Triangles.

In measuring angular distances with the theodolite, the plane of the instrument is carefully adjusted to the horizon, so that the angle observed is the horizontal angle at the station; and, consequently, no previous reduction is necessary, on account of the three summits of the triangle to be computed being unequally distant from the earth's centre, as is the case when the angles are measured with a sextant or repeating circle. The practice which was always followed in the Ordnance survey, of placing the centre of the theodolite directly under the centre of the signal, also obviated the necessity of a calculation for reducing the observed angle to the centre of the station. Formulæ for both these reductions will however be found in FIGURE OF THE EARTH, p. 555.

The three angles of any spherical triangle, as is well known, exceed 180° by a certain quantity, called the *spherical excess*, which is proportional to the area of the triangle. Let A, B, C denote the angles of a spherical triangle, r the radius of the sphere expressed in feet, $\pi = 3{\cdot}14159$ the ratio of the circumference to the diameter, and S the number of square feet in the surface or area of the triangle, then, by trigonometry,

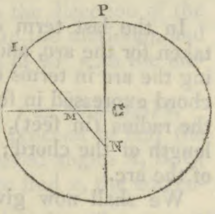
$$\mathrm{S} = \frac{\mathrm{A} + \mathrm{B} + \mathrm{C} - 180^\circ}{180^\circ}\, r^2\pi.$$

Let E denote the spherical excess $= \mathrm{A} + \mathrm{B} + \mathrm{C} - 180^\circ$, then $\mathrm{E} = \frac{\mathrm{S} \times 180^\circ}{r^2\pi}$ in degrees, or $\mathrm{E} = \frac{\mathrm{S} \times 648000''}{r^2\pi}$ expressed in seconds. In any triangle which can be measured on the surface of the earth, S is very small in comparison of r^2, and therefore E is a very small quantity. (In practice it seldom exceeds four or five seconds, though in some of the large triangles observed in the west of Scotland, whose sides exceed 100 miles, it amounted to thirty or forty seconds.) Hence an approximate value of S will enable us to compute E with sufficient precision. For this purpose, therefore, the triangle may be regarded as a plane one; and on denoting by a, b, c, the number of feet in the sides respectively opposite to A, B, C, we shall have for the area, $\mathrm{S} = \frac{1}{2}ab \sin. \mathrm{C}$. Substituting this in the formula for the spherical excess, we get, in seconds,

$$\mathrm{E} = \frac{ab \sin. \mathrm{C} \times 648000}{2r^2\pi} \ldots\ldots\ldots\ldots\ldots\ldots (1).$$

This formula is deduced on the hypothesis that the tri-ngle is on a spherical surface, but it applies also to triangles n the surface of a spheroid; for it may be demonstrated nat the spherical excess is the same for triangles on a pheroid and on a sphere, when the latitudes of the stations nd their differences of longitudes are the same.

In order to compute the spherical excess of any triangle, is necessary to know the value of r, the radius of curva-ire of the spherical surface. Now the curvature of the c joining any two stations on a spheroid varies with the titude of the stations, and also with the direction of the c in question in respect of the meridian; but for the pre-nt purpose it will, in general, be sufficient to assume the lue of r, which corresponds to the curvature of the meri-an at the mean latitude of the stations, and even to sup-se it constant for a whole series of triangles contained be-een two parallels of latitude not distant more than a few grees. If, however, the triangles are very large, it may necessary to compute more accurately; and in such ses the nearest approximation to the true spherical ex-ss will be found by computing, for the mean latitude of e three stations, the curvature of the meridian, and of the rcle perpendicular to the meridian, and taking the mean the two for the value of r; or, which is nearly the same ing, by computing the radius of the vertical circle which ts the meridian at an angle of 45° at that mean latitude. s the determination of the curvature of the meridian, the c perpendicular to the meridian, and the geodetical line aking any oblique angle with the meridian, are required for rious other purposes connected with the survey as well the present, we shall here subjoin the formulæ by which ey are severally computed from assumed dimensions and ipticity of the earth.



Let ALP be the arc of the meridian passing through e station L, AC the semidiameter the equator, CP the semi-axis, M the normal at L, meeting PC oduced in N. Assume a = C P, = AC, and e = the ellipticity, or ch that $b = a(1 + e)$, and let ne the latitude of L, and R the dius of curvature of the meri-in at L; then it is shown in FI-RE OF THE EARTH, p. 559, that

$$R = a(1 - e + 3e \sin.^2 l)\text{...........}(2).$$

Let R′ be the radius of curvature of the arc perpendicu-r to the meridian at L; and it is shown in the same ar-le, p. 558, that R′ = LN, the normal extended to its in-rsection with the polar axis. Now let n = LM, the nor-l at L; then, by conic sections, $R' : n :: b^2 : a^2$; whence $= (1 + e)^2 n$. But $n = a(1 - e \cos.^2 l)$ (FIGURE OF THE ARTH, p. 559); therefore, rejecting terms containing the uare of e, as insignificant, we find

$$R' = a(1 + e + e \sin.^2 l)\text{............}(3).$$

To find the curvature of the oblique circle, let r be the dius of curvature at the point L of a section of the spheroid ntaining LN, and making with the meridian an angle $= \theta$; have the following expression found by Euler (Lacroix, lcul. *Differentiel et Integral*, vol. i. p. 578).

$$r = \frac{RR'}{R \sin.^2 \theta + R' \cos.^2 \theta}.$$

This last expression may be put under a form more con-nient for calculation. Dividing both terms by r', substi-ting $1 - \sin.^2 \theta$ for $\cos.^2 \theta$, and converting the result into series, all the terms of which after the second may be ne-ected, we get

$$r = R\left(1 + \frac{R' - R}{R'} \sin.^2 \theta\right)\text{............}(4).$$

Since in any circle the length of a degree is proportional the radius (it is found by dividing the radius by the constant number 57·29578), if we make M = the length in feet of a degree of the meridian at L, P = the length of a degree of the perpendicular arc, and D = the degree of an arc which makes with the meridian an angle $= \theta$, we shall have also

$$D = M\left(1 + \frac{P - M}{P} \sin.^2 \theta\right)\text{.........}(5),$$

which is the expression usually given, and by means of which the length of the oblique degree is found in terms of the degrees of the meridian and perpendicular.

Apportionment of error of observation.

Having computed the spherical excess E from approximate values of the lengths of the sides (obtained by supposing the triangle a plane one), the sum of the three observed angles should be = 180° + E. But as every observation is attended with some degree of uncertainty, the probability is infinitely small that the sum will be precisely equal to this quantity in any case. The difference (which in general will amount to some seconds) is the error of the observed angles; and the next question to be considered is, how should the error be apportioned among the three angles, so that the probability of the result being true may be greater than if any other mode of distribution were adopted? If no reason exists for supposing that one angle has been determined more accurately than another, the error should of course be equally divided among the three angles; but in practice this is seldom the case, for it will usually happen that one or other of the angles has been determined by a greater number of observations, or by observations made under more favourable circumstances than the others, and consequently the three determinations are not affected with the same probable errors. In the earlier period of the Ordnance survey, and indeed so far as the published account extends, the apportionment of the error appears to have been made in a manner entirely arbitrary, or at least according to the observer's judgment of the relative goodness of the observations; but this objectionable practice is now abandoned, and a uniform method, founded on the theory of chances, adopted. Suppose several observations to have been made of the same angle, and that the seconds of reading are l, l' l'', &c., and let m be the average or arithmetical mean of the whole; then $m - l$, $m - l'$, $m - l''$, &c., are the errors of the individual observations, and the *weight* of the determination, or of the average m, is equal to the square of the number of observations divided by twice the sum of the squares of the errors. See PROBABILITY, vol. xviii. p. 635, No. 145. In this manner the *weight* is found for each angle, and the error of the triangle, that is, the difference between the sum of the three angles (each being the average of the observed values) and 180° + E, is divided into three parts respectively proportioned to the reciprocal of the weights, which parts form the corrections to be added to or subtracted from the angles to which they respectively correspond. We have then three corrected spherical angles, the sum of which is exactly 180° + E.

Methods of calculating the sides.

The three spherical angles of the triangle being thus determined, the next step in the operation is to compute the lengths of the two remaining sides; one side being always known, either by the measurement of a base, or by the previous computation of another triangle. Three different methods of computation have been practised. That which first suggests itself is to transform the side whose length is already known in feet, into an arc of a circle (which is done by comparing it with the radius of the earth), and solving the triangle by the usual formulæ of spherical trigonometry. This was the method followed by Boscovich in his measurement of the Italian arc of meridian; and it was also practised in some instances by Delambre; but as it involves a somewhat tedious process of calculation, it is not that which is generally adopted. As the distance of any two stations mutually visible from each other is very small in comparison of the whole circumference of the earth, the chord of the intercepted arc will

Trigonometrical Survey.

differ from the arc itself by a quantity which may be computed from the known ratio of the chord to the radius of the earth, but which in general is so small as to be insensible. If, therefore, from the observed spherical angles we deduce in each case the corresponding angles formed by the chords, and with these compute the sides by plane trigonometry, we shall obtain the chords of the arcs intercepted between the stations, and thence the arcs themselves, or the true geodetical lines on the spheroid. On this principle all the triangles of the Ordnance survey have been computed. A third method, which has been followed in all the recent continental surveys, and which was also adopted by Captain Kater in the verification of General Roy's triangles, depends on a theorem first demonstrated by Legendre; namely, that a triangle on a sphere or spheroid, which is small in comparison of the whole spherical surface, differs insensibly from a plane triangle of which the sides are respectively equal in length to the sides of the triangle on the sphere, and whose angles are respectively equal to those of the spherical triangle, each diminished by one third of the spherical excess. We shall here give formulæ for the two last methods, with an example of their application.

Formula for reduction to the chords.

To reduce an observed horizontal angle to the angle formed by the chords of the containing sides, let r be the radius of the sphere on which the triangle is described; a, b, c, the sides (the radius and sides being both expressed in feet); and, for the sake of abridging, let

$$\frac{a}{r} = \alpha, \ \frac{b}{r} = \beta, \frac{c}{r} = \gamma;$$

so that α, β, γ, represent the sides of a similar triangle on a sphere whose radius $= 1$. Let A be the horizontal angle opposite the side a, and $A - x$ the corresponding angle formed by the chords; the object is to find the correction x to be applied to the observed angle A. From a well-known formula of plane trigonometry, we have

$$\text{Cos.}\,(A - x) = \frac{\text{chord}^2\,\beta + \text{chord}^2\,\gamma - \text{chord}^2\,\alpha}{2\ \text{chord}\,\beta \times \text{chord}\,\gamma};$$

or, since chord $\alpha = 2 \sin. \tfrac{1}{2}\alpha$,

$$\text{Cos.}\,(A - x) = \frac{\sin.^2 \tfrac{1}{2}\beta + \sin.^2 \tfrac{1}{2}\gamma - \sin.^2 \tfrac{1}{2}\alpha}{2 \sin. \tfrac{1}{2}\beta \times \sin. \tfrac{1}{2}\gamma}.$$

Now $\cos.\,(A - x) = \cos. A \cos. x + \sin. A \sin. x$; and since x is small, $\cos. x = 1$, and $\sin. x = x$ (very nearly); therefore

$$\text{Cos.}\,(A - x) = \cos. A + x \sin. A,$$

and consequently

$$\text{Cos.}\,A + x \sin. A = \frac{\sin.^2 \tfrac{1}{2}\beta + \sin.^2 \tfrac{1}{2}\gamma - \sin.^2 \tfrac{1}{2}\alpha}{2 \sin. \tfrac{1}{2}\beta \times \sin. \tfrac{1}{2}\gamma} \ldots (A).$$

Now in any spherical triangle

$$\text{Cos.}\,A = \frac{\cos. \alpha - \cos. \beta \cos. \gamma}{\sin. \beta \sin. \gamma}$$

$$= \frac{1 - 2 \sin.^2 \tfrac{1}{2}\alpha - (1 - 2 \sin.^2 \tfrac{1}{2}\beta)(1 - 2 \sin.^2 \tfrac{1}{2}\gamma)}{4 \sin. \tfrac{1}{2}\beta \cos. \tfrac{1}{2}\beta \times \sin. \tfrac{1}{2}\gamma \cos. \tfrac{1}{2}\gamma},$$

$$= \frac{\sin.^2 \tfrac{1}{2}\beta + \sin.^2 \tfrac{1}{2}\gamma - \sin.^2 \tfrac{1}{2}\alpha}{2 \sin. \tfrac{1}{2}\beta \cos. \tfrac{1}{2}\beta \times \sin. \tfrac{1}{2}\gamma \cos. \tfrac{1}{2}\gamma} - \frac{\sin. \tfrac{1}{2}\beta \sin. \tfrac{1}{2}\gamma}{\cos. \tfrac{1}{2}\beta \cos. \tfrac{1}{2}\gamma};$$

therefore, by reason of the equation (A),

$$\text{Cos.}\,A = \frac{\cos. A + x \sin. A}{\cos. \tfrac{1}{2}\beta \cos. \tfrac{1}{2}\gamma} - \frac{\sin. \tfrac{1}{2}\beta \sin. \tfrac{1}{2}\gamma}{\cos. \tfrac{1}{2}\beta \cos. \tfrac{1}{2}\gamma};$$

whence we find

$$x \sin. A = \sin. \tfrac{1}{2}\beta \sin. \tfrac{1}{2}\gamma - (1 - \cos. \tfrac{1}{2}\beta \cos. \tfrac{1}{2}\gamma) \cos. A.$$

Now the arcs β and γ being small, we may assume, without sensible error, $\sin. \tfrac{1}{2}\beta = \tfrac{1}{2}\beta$, $\cos. \tfrac{1}{2}\beta = 1 - \tfrac{1}{8}\beta^2$; whence (making also the like assumption for γ), we get

$$x \sin. A = \frac{\beta\gamma}{4} - \frac{\beta^2 + \gamma^2}{8} \cos. A;$$

therefore, since $\tfrac{1}{4}\beta\gamma = \tfrac{1}{16}(\beta + \gamma)^2 - \tfrac{1}{16}(\beta - \gamma)^2$, and $\tfrac{1}{8}(\beta^2 + \gamma^2) = \tfrac{1}{16}(\beta + \gamma)^2 + \tfrac{1}{16}(\beta - \gamma)^2$, $x \sin. A = \tfrac{1}{16}(\beta + \gamma)^2 (1 - \cos. A) - \tfrac{1}{16}(\beta - \gamma)^2 (1 + \cos. A)$, and consequently, dividing both sides by sin. A,

$$x = \tfrac{1}{16}(\beta + \gamma)^2 \tan. \tfrac{1}{2}A - \tfrac{1}{16}(\beta - \gamma)^2 \cot. \tfrac{1}{2}A.$$

In this formula x is expressed in parts of the radius $= 1$; but in the applications x must be expressed in seconds of arc. Now if R'' denote the number of seconds in the radius $(= 206{,}264''\cdot 8)$, then $1 : x :: R''$: seconds in arc x; whence $x\,R'' =$ seconds in x. Multiplying therefore the above equation by R'', and substituting for α, β, γ, their values, we have ultimately

$$x = \tfrac{1}{16}\left(\frac{b + c}{r}\right)^2 \tan. \tfrac{1}{2}A \cdot R'' - \tfrac{1}{16}\left(\frac{b - c}{r}\right) \cot. \tfrac{1}{2}A \cdot R'' \ (6),$$

from which formula x is found in seconds.

In like manner, the corrections are found for the two other horizontal angles B and C, each being expressed in terms of the angle itself and its containing sides. Let these corrections be respectively x' and x'', then it is evident that $x + x' + x'' = E$, the spherical excess, and consequently, that when the true horizontal angles are respectively diminished by x, x', and x'', the sum of the three angles thus reduced will be exactly 180°. These reduced angles are the angles for calculation; and on computing from them the sides, we obtain the chords of the spherical arcs intercepted between the stations, whence the arcs themselves are easily obtained by means of the following formula:

Let φ be any small arc in parts of the radius $= 1$; then chord $2\varphi = 2 \sin. \varphi$; but we have also $\sin. \varphi = \varphi - \tfrac{1}{6}\varphi^3$, therefore chord $2\varphi = 2\varphi - \tfrac{1}{3}\varphi^3$. Now, if we assume $2\varphi = \frac{a}{r}$, or $\varphi = \frac{a}{2r}$; then chord $\frac{a}{r} = \frac{a}{r} - \frac{a^3}{24r^3}$, and consequently

$$a = \text{chord}\,a + \frac{a^3}{24r^2}. \ldots\ldots\ldots\ldots\ldots\ldots (7).$$

In the last term of this expression the chord may be taken for the arc, and we have therefore this rule for finding the arc in terms of the chord. Divide the cube of the chord expressed in feet by twenty-four times the square of the radius (in feet), and add the result to the computed length of the chord; the sum is the corresponding length of the arc.

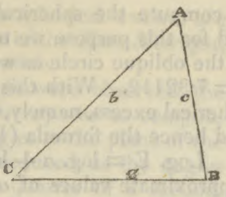
We shall now give an example of the application of the preceding formulæ by computing the sides of one of the large triangles connecting the west of Scotland with Ireland, with the requisite data for which we have been obligingly furnished by Colonel Colby. The three stations or angular points are Benlomond in Stirlingshire, Cairnsmuir-on-Deugh in Kirkcudbright, and Knocklayd in the county of Antrim; the longest side, from Benlomond to Knocklayd, exceeding ninety-five miles. The data are as follows

At Benlomond the angle subtended by the stations on Knocklayd and Cairnsmuir-on-Deugh was determined from three observations, giving respectively (we repeat only the seconds) 56° 43′ 29″·97, 27″·04, 28″·72. The mean is 56° 43′ 28″·58; whence the errors are respectively + 1·39, — 1·54, + 0·14; the squares of the errors 1·9321, 2·3716, ·0196; the sum of the squares 4·3233; the weight (the square of the rule of observations divided by twice the sum of the squares of the errors) = 9 ÷ 8·6466 = 1·041; and the reciprocal of the weight ·961.

At Cairnsmuir-on-Deugh, one observation gave the angle 79° 42′ 28″·69. The weight is assumed = ·1, whence the reciprocal of the weight is 10.

At Knocklayd, two observations gave the angles 43° 34′ 38″·36, and 35″·43. The mean is 43° 34′ 36″·89; the errors respectively + 1·47 and — 1·46; the weight found as above = ·4660; and the reciprocal of the weight 2·146.

We have therefore the following data for the computation of the triangle:



enlomond..... A = 56° 43′ 28″·58
airnsmuir...... B = 79 42 28 ·69
nocklayd...... C = 43 34 36 ·89

um............... 180 0 34 ·16

ogether with the chord of the arc oining A and B, obtained from the omputation of a former triangle, iz. chord c = 352,033·48 feet.

The first step of the operation is to compute approximate alues of the two sides a, b. For this purpose we have the ormulæ $a = \frac{c \text{ sin. A}}{\text{sin. C}}$, $b = \frac{c \text{ sin. B}}{\text{sin. C}}$; and it will be sufficient use logarithms to five places.

Log. c = 5·54658	Log. c = 5·54658
Log. sin. A = 9·92223	Log. sin. B = 9·99295
Co. log. sin. C = 0·16158	Co. log. sin. C = 0·16158
Log. a = 5·63039	Log. b = 5·70111

ence the approximate values of the three sides are = 426,960, b = 502,470, c = 352,030 feet.

We have next to find the corrections for reducing the served angles to the chord angles, and for this purpose it necessary to have an approximate value of the curvature the surface. Now the approximate latitude of Benmond (the northernmost station) is 56° 11′, and that of nocklayd (the southernmost) is 55° 10′; the mean of the o is 55° 40′; and if we adopt this as the value of l, and sume the elements of the spheroid given in the article IGURE OF THE EARTH, p. 563, viz. a = half the polar is = 20,852,394 feet, $e = \frac{b-a}{a} = \frac{1}{301\cdot026} = \cdot003322$, e formulæ (2), (3), and (4), give the following values of , R′, and r (the radii of curvature in the direction of the eridian, the direction perpendicular to the meridian, and e direction of a line making an angle of 45° with the melian) in feet, viz.

R = 20,924,824, R′ = 20,968,900, r = 20,946,814.

With the value of r thus found, we proceed to find the ord angles corresponding to the observed angles A, B, C, means of equation (6). And first to find x, the correcn for A.

Log. $(b + c)$ = 5·93171	Log. $(b - c)$ = 5·17734
Log. r = 7·32112	Log. r = 7·32112
8·61059	7·85622
2	2
7·22118	5·71244
Log. tan. ½ A = 9·73235	Log. cot. ½ A = 0·26765
Co. log. 16 = 8·79588	Co. log. 16 = 8·79588
Log. R″ = 5·31443	Log. R″ = 5·31443
11″·583 = 1·06384	1″·231 = 0·09040

Hence x = 11″·583 — 1″·231 = 10″·352. As the corrections for the other angles B and C are found precisely in the same manner, it is unnecessary to give the calculation. The results are respectively x' = 14″·684, x'' = 9″·724.

From this we have the spherical excess E $(= x + x' + x'')$ = 34″·760. But the excess of the sum of the three observed angles above 180° was 34″·16, consequently the error of the observations is — 0″·60. Now, on dividing this error into three parts proportionally to the three numbers ·961, 10, 2·146 (the reciprocals of the weights), we find the corrections for the observed angles to be respectively + 0″·04, + 0″·46, and + 0″·10. On applying these corrections, we obtain the true spherical angles; and on diminishing each of these last by the corresponding corrections for reduction to the chords, viz. 10″·35, 14″·68, 9″·73, we obtain the chord angles, or angles for calculation. The results are as follows:

	Observed Angles.	Spherical Angles.	Chord Angles.
A	56° 43′ 28″·58	56° 43′ 28″·62	56° 43′ 18″·27
B	79 42 28 ·69	79 42 29 ·15	79 42 14 ·47
C	43 34 36 ·89	43 44 36 ·99	43 34 27 ·26
	180 0 34 ·16	180 0 34 ·76	180 0 0 ·00

Calculation of the chords.

With the angles in the last column of this table, we are enabled to calculate the lengths of the chords opposite A and B. It is now necessary to use logarithms to seven decimals at least. The calculation is as follows.

Log. chord c (= 352033·48) = 5·5465840
Log. sin. A (56° 43′ 18″·27) = 9·9222144
Log. sin. B (79 42 14 ·47) = 9·9929499
Co.log. sin. C (43 34 27 ·26) = 0·1615956

Log. chord a = 5·6303940
Log. chord b = 5·7011295

and the results are, chord a = 426,966·69 feet, chord b = 502,492·46 feet, chord c = 352,033·48 feet.

Calculation of the arcs.

It now only remains to determine the spherical arcs corresponding to the above chords. Using the same value of the radius as above, namely, log. r = 7·32112, we find

$$\frac{a^3}{24r^2} = 7\cdot39,\quad \frac{b^3}{24r^2} = 12\cdot05,\quad \frac{c^3}{24r^2} = 4\cdot14,$$

and therefore, by equation (7), the distances on the surface of the spheroid are,

Cairnsmuir to Knocklayd..............a = 426,974·08
Benlomond to Cairnsmuir..............b = 502,504·51
Benlomond to Knocklayd..............c = 352,037·62

The whole process is brought under one view, by arranging the calculations as in the subjoined table.

Stations	Observed Angles.	Observations.		Chord Corrections.	Appor. of Error.	Angles for Calculation.	Calculation.	Chord Sides opposite each Angle.	Lengths of Arcs.
		No.	Recip. of Weight.						
							5·5465840		
Benlomond...	56° 43′ 28″·58	3	0·961	— 10·35	+ 0·04	56° 43′ 18″·27	9·9222144	426966·69	426974·08
Cairnsmuir...	79 42 28 ·69	1	10·000	— 14·68	+ 0·46	79 42 14 ·47	9·9929499	502492·46	502504·51
Knocklayd....	43 34 36 ·89	2	2·146	— 9·73	+ 0·10	43 34 27 ·26	0·1615956	352033·48	352037·62
	180 0 34 ·16			34·76			5·6303940		
	Error, — 0 ·60						5·7011295		

The method now explained is that which has been followed in computing all the triangles of the Ordnance survey. The following, which is generally adopted in the continental measurements of geodetical arcs, is of somewhat easier application.

Legendre's theorem.

As before, let $a \div r$, $b \div r$, $c \div r$, be represented respectively by α, β, γ. We have then

$$\text{Cos. A} = \frac{\cos.\ \alpha - \cos.\ \beta \cos.\ \gamma}{\sin.\ \beta \sin.\ \gamma};$$

and since the ares a, b, c, are small in comparison of r, a sufficient approximation will be obtained, if, in the development of the sines and cosines in terms of the arc, we retain the terms only which involve powers not higher than the fourth, that is, if we make

$$\text{Cos. } \alpha = 1 - \frac{\alpha^2}{2} + \frac{\alpha^4}{2 \cdot 3 \cdot 4}\text{; sin. } \beta = \beta - \frac{\beta^3}{2 \cdot 3};$$

and also make a like substitution for cos. β, cos. γ, and sin. γ. With these values, the above equation becomes

$$\text{Cos. A} = \frac{\frac{1}{2}(\beta^2 + \gamma^2 - \alpha^2) + \frac{1}{24}(\alpha^4 - \beta^4 - \gamma^4) - \frac{1}{4}\beta^2\gamma^2}{\beta\gamma\left\{1 - \frac{1}{6}(\beta^2 + \gamma^2)\right\}}$$

$$= \frac{\beta^2 + \gamma^2 - \alpha^2}{2\beta\gamma} + \frac{\alpha^4 + \beta^4 + \gamma^4 - 2\alpha^2\beta^2 - 2\alpha^2\gamma^2 - 2\beta^2\gamma^2}{24\beta\gamma}.$$

Restoring the values of α, β, γ, and denoting the numerators of the two terms by M and N respectively, we have

$$\text{Cos. A} = \frac{\text{M}}{2bc} + \frac{\text{N}}{24bcr^2} \ldots\ldots\ldots\ldots\ldots\ldots (8).$$

In a plane triangle whose sides are respectively equal in length to the three arcs a, b, c, let A′ be the angle opposite to the side a; then

$$\text{Cos. A}' = \frac{b^2 + c^2 - a^2}{2bc} = \frac{\text{M}}{2bc}.$$

On squaring both sides of this equation, and substituting $1 - \sin.^2 \text{A}'$ for $\cos.^2 \text{A}'$, we get $-4b^2c^2 \sin.^2 \text{A}' = a^4 + b^4 + c^4 - 2a^2b^2 - 2a^2c^2 - 2b^2c^2 = \text{N}$. In consequence of these two values of M and N, the equation (8) becomes

$$\text{Cos. A} = \cos.\ \text{A}' - \frac{bc}{6r^2} \sin.^2 \text{A}'.$$

If we now assume $\text{A} = \text{A}' + x$, then x will obviously be a very small arc, and we may suppose cos. $x = 1$, and sin. $x = x$, without sensible error. Hence cos. A = cos. A′ — x sin. A′, and we have therefore $x = \frac{bc}{6r^2} \sin.\ \text{A}'$; whence

$$\text{A} = \text{A}' + \frac{bc}{6r^2} \sin.\ \text{A}'.$$

Now, $\frac{1}{2}bc \sin.\ \text{A}'$ is the area of the rectilineal triangle whose sides are a, b, c, and which does not sensibly differ from the spherical triangle; therefore, denoting this area by S, and observing that a similar result will be found for B and C, we shall have $\text{A} = \text{A}' + \frac{1}{3}(\text{S} \div r^2)$, $\text{B} = \text{B}' + \frac{1}{3}(\text{S} \div r^2)$, $\text{C} = \text{C}' + \frac{1}{3}(\text{S} \div r^2)$; therefore, since $\text{A}' + \text{B}' + \text{C}' = 180°$, $\text{A} + \text{B} + \text{C} - (\text{S} \div r^2) = 180°$, so that $\text{S} \div r^2$ may be regarded as the excess of the three angles A, B, C of the spherical triangle above two right angles.

From this demonstration it follows, that if from each of the angles of any small triangle on the surface of a sphere or spheroid (for the proposition holds true for both surfaces) one third of the spherical excess be deducted, the sines of the angles thus diminished will be proportional to the lengths of the opposite sides, and consequently the sides may be computed as if the triangle were rectilineal. It is to be remarked, that the angles to be diminished by one third of the spherical excess, are not the observed angles, but the horizontal angles corrected for the errors of observation.

Calculation by Legendre's method.

As an example of this method, we shall take the same triangle as before.

The three angles having been observed, the first step is to compute the spherical excess E from the formula (1), and for this purpose we take the same value of the radius of the oblique circle as was determined above, namely, log. $r = 7{\cdot}32112$. With this radius, the constant part of the spherical excess, namely, $648000 \div 2r^2\pi$, becomes 0·37116, and hence the formula (1) becomes

$$\text{Log. E} = \log.\ a + \log.\ b + \log.\ \sin.\ \text{C} + 0{\cdot}37116.$$

Approximate values of a and b (one of them may be the given side) must now be found. Now, we found above log. $a = 5{\cdot}63039$, log. $b = 5{\cdot}70111$; and we have also log. sin. C = 9·83842. Adding these and the constant number 0·37116 into one sum, we get log. E = 1·54108, and consequently E = 34″·760. This value of the spherical excess agrees exactly (as it ought) with the sum of the three chord corrections found above.

Having computed the spherical excess, the error of the three observed angles is found, and apportioned among the angles in the reciprocal proportion of their respective weights, and the correct spherical angles deduced in the same manner as already explained in describing the other method. Each of the spherical angles is then diminished by $\frac{1}{3}$ E = 11″·58$\frac{2}{3}$; and the results are the *mean* angles from which the sides are to be calculated. They are as under:

Stations.	Corrected Spherical Angles.	Mean Angles for Calculation.
Benlomond, A...	56° 43′ 28″·62	56° 43′ 17″·04
Cairnsmuir, B...	79 42 29 ·15	79 42 17 ·56
Knocklayd, C....	43 34 36 ·99	43 34 25 ·40
Sum......	180 0 34 ·76	180 0 0 ·00

With these mean angles, and the given side $c = 352{,}037{\cdot}62$ feet (in this case the arc is taken, and not the chord), we can now compute the other sides a, b.

Log. c (= 352,037·62) = 5·5465891
Log. sin. A (56° 43′ 17″·04) = 9·9222127
Log. sin. B (79 42 17 ·56) = 9·9929511
Co. log. sin. C (43 34 25 ·40) = 0·1615997

Log. a = 5·6304015
Log. b = 5·7011399

whence a = 426,974·06 feet, and b = 502,504·42 feet. These results agree almost exactly with those obtained by the reduction to the chord angles, the greatest difference being less than a tenth of a foot in a distance exceeding ninety-five miles.

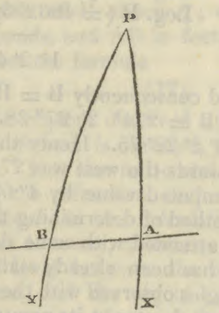
On comparing the two methods of calculation which have now been explained, it will be obvious that the latter, or that of Legendre, is the simpler of the two, inasmuch as it requires only the calculation of the spherical excess by a single operation, whereas the reduction to the chords requires an equivalent operation for each of the three angles. The calculation of the chord angles is however, in practice, rendered easy by an auxiliary table, in which the correction is given for different values of the angle, and of the sum and difference of its containing sides. But the spherical excess may be entered in a table in the same manner. A sufficient approximation to this quantity, or rather to the area of the triangle on which the excess depends, may frequently be obtained by making a plan of the triangle, and measuring the length of the perpendicular upon the known side by means of a scale of equal parts. In fact, if the three angles have been equally well observed, so that the error is to be divided equally among them, the calculation of the spherical excess is not even necessary for computing the sides; as the same mean angles will be obtained by diminishing each of the observed angles by one third of the excess of the sum above 180°. Tables for the reduction of the spherical angles to the plane of the chords, and lewise for the computation of the spherical excess, are ven by Delambre in the first volume of the *Base Métrique*, d also in Puissant's *Traité de Géodésie*.

When two angles only of a triangle were observed, the pactice adopted in the Ordnance survey was to compute te reduction of the two observed angles to the plane of the cords, and to give the angles thus reduced, as the angles f calculation, true to the nearest quarter of a second. Te third angle was then assumed, so that when added to t two chord angles the sum was 180°.

Calculation of the Latitudes, Longitudes, and Azimuths.

The formulæ which have now been given suffice for the cnputation of the sides of the principal triangles, or the dtances of the stations from each other; but for the purpe of mapping the country, it is also necessary to determne the latitudes and longitudes of the several stations, a the inclinations of the sides of the triangles to the merian. In order to effect this by means of the geodetical nasurements, the latitude of one station at least, and the ilination of a side of one of the triangles to the meridian o hat station, must be determined by astronomical means; a when this has been done, the geographical latitudes a longitudes of all the other stations in a chain of triales, and the inclinations of their several sides to the mridians which pass through their extremities, may be cmputed. The computation, however, is of such a nature th a small error in determining the direction of the merid n leads to errors of considerable magnitude in the latitues and longitudes deduced from it; and it accordingly bomes necessary, in the progress of a large survey, to vefy the computed results by astronomical observations at arious stations not very remote from each other in respct of longitude. It has been stated in the preceding hiorical sketch, that eight different meridians were determed by direct observation in the progress of the survey of England. The problem which usually occurs in practi may be enunciated as follows.

iven the latitude and longitude of a station A, and the diance of A from another station B, and also the direction of e meridian at A in respect of the straight line AB, to dermine the latitude and longitude of B, and the directi of the meridian at B in respect of AB.



n the surface of a sphere whose cere is at the point where the nonal at A intersects the polar ax of the spheroid, let PAX be th meridian of A, PBY the merin of B, meeting the former in P then in the spherical triangle P B there are given PA the colaude of A, the side AB determed from the triangulation, and th observed angle PAB which (ihe annexed figure) is the supplent of the azimuth at A, the az uths being supposed to be reoned from the south towards the west, all round the cire; and from these data we have to deduce PB the cotitude of B, the angle APB the difference of the longiles of A and B, and PBA, which, added to 180°, is the az uth of A as seen from B.

et $l = 90° - \text{AP} =$ latitude of A,
$l' = 90° - \text{BP} =$ latitude of B,
$\lambda = l - l'$,
$\text{A} = 180° - \text{PAB} =$ azimuth of B seen from A,
$d =$ arc AB in parts of the radius.

Inhe spherical triangle PAB we have

co $\text{PB} = \sin.\text{PA} \sin.\text{AB} \cos.\text{PAB} + \cos.\text{PA} \cos.\text{AB}$;

ths (since $\cos.\text{PAB} = -\cos.(180° - \text{PAB}) = -\cos.\text{A}$),

$$\sin.l' = -\cos.l \sin.d \cos.\text{A} + \sin.l \cos.d,$$

whence

$$\sin.l - \sin.l' = \cos.l \sin.d \cos.\text{A} + \sin.l\,(1 - \cos.d).$$

But $\sin.l - \sin.l' = 2 \sin.\tfrac{1}{2}(l - l') \cos.\tfrac{1}{2}(l + l')$

$$= 2 \sin.\tfrac{1}{2}\lambda \cos.(l - \tfrac{1}{2}\lambda)$$

$$= 2 \sin.\tfrac{1}{2}\lambda\,(\cos.l \cos.\tfrac{1}{2}\lambda + \sin.l \sin.\tfrac{1}{2}\lambda),$$

therefore

$$2 \sin.\tfrac{1}{2}\lambda\,(\cos.l \cos.\tfrac{1}{2}\lambda + \sin.l \sin.\tfrac{1}{2}\lambda) = \cos.l \sin.d \cos.\text{A} + \sin.l\,(1 - \cos.d).$$

Now since λ the difference of the latitudes can only be a small arc, we may reject without sensible error all the terms in the development of the sine and cosine containing higher powers of $\tfrac{1}{2}\lambda$ than the square; that is, we may assume $2 \sin.\tfrac{1}{2}\lambda = \lambda$, $\cos.\tfrac{1}{2}\lambda = 1 - \tfrac{1}{2}(\tfrac{1}{2}\lambda)^2$, $\sin.\tfrac{1}{2}\lambda = \tfrac{1}{2}\lambda$. In like manner, since d is small in comparison of the radius, we may put $\sin.d = d$, $1 - \cos.d = \tfrac{1}{2}d^2$; whence the above equation becomes, on dividing by $\cos.l$,

$$\lambda = d \cos.\text{A} + \tfrac{1}{2}(d^2 - \lambda^2) \tan.l \ldots\ldots\ldots\ldots(9).$$

For a first approximation the second term may be neglected, and we have then $\lambda = d \cos.\text{A}$, which is equivalent to supposing the meridians at the two stations to be parallel. Substituting this value of λ in the second term, we get for a nearer approximation

$$\lambda = d \cos.\text{A} + \tfrac{1}{2} d^2 \sin.^2 \text{A} \tan.l \ldots\ldots\ldots(10).$$

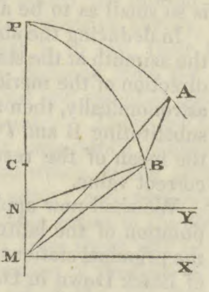
This new value of λ may be again substituted in the equation (9), by which a still nearer value would be obtained; but it is unnecessary to carry the approximation farther.

The difference of latitudes λ is here expressed in parts of the radius 1. Let λ'' be the number of seconds in λ; then $\lambda = \lambda'' \sin.1'' = (l - l') \sin.1''$ ($l - l'$ being also expressed in seconds). The arc d likewise denotes the distance on the sphere from A to B in parts of the radius; therefore, if D be the number of feet in AB, and R′ the number of feet in the radius of the circle perpendicular to the meridian at A, we shall have $d = \text{D} \div \text{R}'$. Making these substitutions, the last equation becomes

$$l - l' = \frac{\text{D} \cos.\text{A}}{\text{R}' \sin.1''} - \frac{\text{D}^2 \sin.^2 \text{A} \tan.l}{2\,\text{R}'^2 \sin.1''} \ldots\ldots(11).$$

Correction for ellipticity.

This formula gives the latitude of the station B, supposing the surface that of a sphere; but a small correction is required on account of the compression. To investigate this, let AM and BN be the normals to the spheroidal surface meeting the polar axis in M and N; join BM, and draw MX and NY parallel to the plane of the equator. The angle AMX is the astronomical latitude of the station A, or the latitude l, and the angle BMX is the latitude of B, determined by the above formula. But the true astronomical latitude of B is the angle BNY, which is less than BMX by the angle MBN; we have therefore to compute this angle, and add its value to λ, the difference between l and l'. Let $\text{MBN} = \psi$. In the triangle BMN we have $\sin.\psi : \sin.\text{BNM} :: \text{MN} : \text{MB}$. Now $\sin.\text{BNM} = \cos.\text{BNY} = \cos.l'$; and if C be the centre of the spheroid, then $\text{MN} = \text{CM} - \text{CN}$; and because AB is always a small arc on the spheroid, MB is sensibly equal to AM; therefore the above proportion gives $\text{AM} \sin.\psi = (\text{CM} - \text{CN}) \cos.l'$. If we now assume a and b to denote respectively the polar and equatorial semidiameters, we readily find, from the equation of the ellipse, $\text{CM} = \dfrac{b^2 - a^2}{b^2} \text{AM} \sin.l$. Substituting $a(1 + e)$ for b, developing, and rejecting terms multiplied by powers of e, we have $(b^2 - a^2) \div b^2 = 2e$; whence $\text{CM} = 2e\,\text{AM} \sin.l$. In like manner, $\text{CN} = 2e\,\text{AM} \sin.l'$; consequently



$$\sin.\psi = 2e(\sin. l - \sin. l')\cos. l'.$$

Now, $\sin. l - \sin. l' = 2\sin.\frac{1}{2}(l - l')\cos.\frac{1}{2}(l + l')$; and by reason of the smallness of e we may put $\cos.\frac{1}{2}(l + l')\cos. l' = \cos.^2 l$; therefore $\sin.\psi = 2e\sin.\lambda\cos.^2 l$, or $\psi = 2e\lambda\cos.^2 l$. This is the correction for the spheroidicity; the corrected difference of latitudes is consequently $\lambda + \psi = \lambda(1 + 2e\cos.^2 l)$. Hence on the spheroid the equation (11) becomes

$$l - l' = \left\{\frac{D\cos. A}{R'\sin. 1''} + \frac{D^2\sin.^2 A\tan. l}{2R'^2\sin. 1''}\right\}(1 + 2e\cos.^2 l)\ldots(12).$$

Difference of longitude.

To find the difference of the longitudes of A and B, or the angle at the pole, we have in the above triangle sin. P : sin. PAB : : sin. AB : sin. PB; that is, since P and AB are small, P : sin. A : : d : cos. l'; whence $P = d\sin. A \div \cos. l'$ in parts of the radius, or in seconds of arc

$$P = \frac{D\sin. A}{R'\cos. l'\sin. 1''}\ldots\ldots\ldots\ldots\ldots\ldots\ldots(13).$$

Azimuth.

Let B be the azimuth of AB on the horizon of the station B. To find B we may employ the following property of spherical triangles, which also holds good for triangles on a spheroid, viz. $\tan.\frac{1}{2}P : \cot.\frac{1}{2}(PAB + PBA) : : \cos.\frac{1}{2}(PB - PA) : \cos.\frac{1}{2}(PB + PA)$; that is, since $PAB = 180° - A$, and $PBA = B - 180°$, and consequently $PAB + PBA = B - A$,

$$\cot.\tfrac{1}{2}(B - A) = \tan.\tfrac{1}{2}P\,\frac{\sin.\frac{1}{2}(l + l')}{\cos.\frac{1}{2}(l - l')}.$$

Now $\cot.\frac{1}{2}(B - A) = \tan.\{90° - \frac{1}{2}(B - A)\}$; and since the difference of the two azimuths, or, which is the same, the sum of the two angles PAB and PBA, is always very nearly equal to 180°, the angle $90° - \frac{1}{2}(B - A)$ is always very small, and we may therefore substitute the arc for the tangent without sensible error. For the same reason we may take $\frac{1}{2}P$ for $\tan.\frac{1}{2}P$. Making these substitutions, doubling, and transposing, we get

$$B = 180° + A - P\,\frac{\sin.\frac{1}{2}(l + l')}{\cos.\frac{1}{2}(l - l')}\ldots\ldots\ldots\ldots\ldots(14).$$

The two formulæ (13) and (14) require no correction on account of the ellipticity; for with respect to the first, the angle APB at the pole is the same on the spheroid as on the sphere; and with respect to the second, the correction is so small as to be altogether insensible.

In deducing the above formulæ, it has been supposed that the azimuth at the station A only has been observed. If the direction of the meridian at B has likewise been determined astronomically, then another value of P will be obtained by substituting B and l for A and l' in the equation (13); and the mean of the results should of course be taken as the correct value.

Example of the formulæ.

We shall now apply the preceding formulæ to the computation of the latitude, longitude, and azimuth of one of the principal stations of the survey; and we shall select that of Black Down in Dorsetshire, referring it to the station at Dunnose in the Isle of Wight. The following elements are given in the Survey, vol. ii. p. 88, *et seq.* Distance of Black Down from Dunnose $= D = 314{,}307\cdot5$ feet ($= 59\cdot528$ miles); latitude of Dunnose $= l = 50°\ 37'\ 7''\cdot3$; angle at Dunnose between Black Down and the direction of the meridian towards the north $(= 180° - A) = 84°\ 54'\ 52''\cdot5$. From this last angle it is obvious that Black Down lies westward and a little to the north of Dunnose.

Assuming the same elements of the spheroid as before, we have $e = \cdot003324$; whence we easily find $1 + 2e\cos.^2 l = 1\cdot00267$, the logarithm of which is 0·00116. We have also from the formula (3) the radius of the circle perpendicular to the meridian = 20,963,000 feet, in round numbers; with this value of R′, and the given value of D, the computation of the equation (12) is as follows:

$$\begin{array}{ll}
\text{Log. } D & = 5\cdot49735 \\
\text{Log. } R' & = 7\cdot32145 \\
\hline
\text{Log. }(D \div R') & = 8\cdot17590 \\
\text{Log. cos. } A & = 8\cdot94763 \\
\text{Co. log. sin. } 1'' & = 5\cdot31443 \\
\text{Log. }(1 + 2e\cos.^2 l) & = 0\cdot00116 \\
\hline
-274''\cdot87 & = 2\cdot43912
\end{array}
\qquad
\begin{array}{ll}
\text{Log. }(D \div R')^2 & = 6\cdot35180 \\
\text{Log. sin.}^2 A & = 9\cdot99658 \\
\text{Log. tan. } l & = 0\cdot08573 \\
\text{Co. log. 2 sin. } 1'' & = 5\cdot01340 \\
\text{Log. }(1 + 2e\cos.^2 l) & = 0\cdot00116 \\
\hline
+\ 28''\cdot10 & = 1\cdot44867
\end{array}$$

Hence $l - l' = -274''\cdot87 + 28''\cdot10 = -246''\cdot77$ (the first term being negative because cos. A is negative), and $l' = l + 4'\ 6''\cdot77$. But $l = 50°\ 37'\ 7''\cdot30$; therefore $l' = 50°\ 41'\ 14''\cdot07$. In the Survey, vol. ii. p. 91, the latitude of Black Down is found by a different mode of computation $= 50°\ 41'\ 13''\cdot8$.

For the difference of longitude we have to compute the formula $P = D\sin. A \div R'\cos. l'\sin. 1''$ (13). Making use of the value of l' just found, we have

$$\begin{array}{ll}
\text{Log. }(D \div R') & = 8\cdot17590 \\
\text{Log. sin. } A & = 9\cdot99829 \\
\text{Co. log. cos. } l' & = 0\cdot19822 \\
\text{Co. log. sin. } 1'' & = 5\cdot31443 \\
\hline
4862''\cdot3 & = 3\cdot68684
\end{array}$$

Hence $P = 1°\ 21'\ 2''\cdot3$. In the Survey the value of P is found to be $1°\ 20'\ 46''\cdot4$. The difference, which amounts to 16″, arises from the different elements of the earth's figure assumed in the Survey, which give the length of a degree of the circle perpendicular to the meridian at the latitude of Dunnose = 367,038 feet; whereas the length of the degree corresponding to the more correct value of the radius assumed in the preceding calculation is only 365,874 feet. It is now known that the differences of the longitudes of the stations on the southern coast of England are all given too small, in consequence of this erroneous assumption of the length of the perpendicular degree.

The longitude of Dunnose west of Greenwich having been found by a previous operation $= 1°\ 11'\ 36''$, that of Black Down is consequently $2°\ 32'\ 38''\cdot3$.

It now remains to find the azimuth at Black Down, by computing the formula (14). Here we have

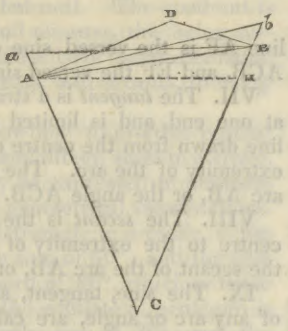
$$\begin{array}{lr}
\text{Log. sin. }\frac{1}{2}(l + l')\ (= 50°\ 39'\ 10''\cdot68) & = 9\cdot88836 \\
\text{Log. cos. }\frac{1}{2}(l' - l)\ (= 0°\ \ 2'\ \ 3''\cdot38) & = 0\cdot00000 \\
\text{Log. } P\ (= 4862''\cdot3) & = 3\cdot68684 \\
\hline
1°\ 2'\ 40''\cdot12 = 3760''\cdot12 & = 3\cdot57520
\end{array}$$

and consequently $B = 180° + 95°\ 5'\ 7''\cdot50 - 1°\ 2'\ 40''\cdot12$, or $B = 274°\ 2'\ 27''\cdot38$. The observed angle PBA was $94°\ 2'\ 22''\cdot75$. Hence the azimuth reckoned from the south towards the west was $274°\ 2'\ 22''\cdot75$, which differs from the computed value by $4''\cdot63$. It may be remarked, that the method of determining the azimuths adopted in the Survey is attended with some degree of uncertainty. It consists, as has been already stated, in taking the mean of the two angles observed with the theodolite between a flag-staff and the pole-star at its greatest elongation west and east. Now, by reason of the altitude of the pole-star in our latitudes above the terrestrial signal, any error in the adjustment of the cross axis of the theodolite to horizontality produces a greater error in the resulting azimuth. Captain Kater (Phil. Trans. 1828, p. 188) considers the observations of the pole-star for determining the perpendicular degree in our latitudes, as wholly unworthy of credit.

Of the Heights of the Stations, and Refraction.

In order to complete the explanation of the methods of calculation employed in the Survey, it only remains to show how the relative altitudes of the principal stations have been determined, and also the amount of atmospheric refraction, which is an element of the same problem.

Let A and B be two stations whose distance from each other is known, and let AC and BC be the directions of gravity, meeting in C, the earth being supposed spherical. Let AD and BD be the horizontal ines in the plane ACB, and uppose a and b to be the apparent planes of A and B respectively, as seen from each ther. Now, if the rays of ight proceeded in straight nes, the angle DAB would e the depression of B below he horizon of A, and DBA ne depression of A below the horizon of B; and since AD nd BD are perpendicular to AC and BC respectively, ne sum of these two angles is equal to C, or to the arc of ne great circle intercepted between A and B. But this rc is known from the measured distance of A from B, and ne assumed dimensions of the earth; consequently the im of DAB and DBA is given. If, therefore, from this iven sum we subtract the sum of the two observed depressions, namely, D Ab and DBa, there will remain the sum f BAb and ABa, that is, the sum of the two refractions, ne half of which is the mean refraction, and assumed to be ne actual refraction at each station. Let us put



d = DAb, the observed depression at A,
d' = DBa, the observed depression at B,
C = ACB, the measure of the contained arc,
ϱ = the mean refraction,

id we have

$$\varrho = \tfrac{1}{2}\{C - (d + d')\} \ldots\ldots\ldots\ldots\ldots (15).$$

Now, let H be the point in CB which is on the same vel surface with A, so that CH = CA; then HB is the altitude of B above A, which we have to determine. Join H, and the angle DAH is equal to half of C. But the ngle BAH is obviously the difference between DAH and ie sum of DAb and bAB. Hence if φ denote the angle AH, we have

$$\varphi = \tfrac{1}{2}C - (d + \varrho) \ldots\ldots\ldots\ldots\ldots\ldots\ldots (16).$$

his gives the angular elevation of B above A; conseiently if φ is expressed in seconds, and AB in feet, then H will be obtained in feet from the formula

$$BH = AB \times \varphi \sin. 1'' \ldots\ldots\ldots\ldots\ldots\ldots (17).$$

It has been assumed that the objects observed at both ations are depressed. If one of them is elevated, then d d' must be taken negatively. It is also to be remarked, iat for the purpose of finding the refraction, each obseration must be reduced, previously to the calculation, to ie axis of the instrument; that is to say, allowance must e made for the difference of level between the axis of ie instrument at either station, and the object (as the p of a flag-staff) at the same station observed from the ther. This allowance is made by computing the angle ibtended by that difference at the distance between the ations, and deducting it from the observed depression, or dding it to the observed elevation.

For the determination of the absolute altitudes, it is neessary that the heights of one or more of the stations be scertained by actually levelling down to the surface of the ea. The heights of all the intermediate stations are then stablished in the manner now explained, by the reciprocal ngles of elevation or depression, carried on from station to tation; and it is obvious that a verification will be obtaind for every three stations; for the difference of altitude between A and B, when found by direct observation, ought to be the same as when deduced from the difference of the heights of each of those stations, and a third station C.

For estimating the altitudes of places at which the theodolite was not placed, and where, consequently, reciprocal observations were not obtained, it was necessary to assume a mean value of the refraction ϱ, in order to obtain the angle φ in the equation (16). On account of the wide limits within which the horizontal refraction is found to vary, this is attended with some uncertainty, even when every attention is paid to the condition of the atmosphere. In general the effect of refraction was assumed to be from $\frac{1}{12}$th to $\frac{1}{14}$th of the whole difference of altitude.

As an example, we select the following case from the Survey. At the station of Black Comb in Cumberland, Scilly Bank appeared depressed 49′ 14″; and at Scilly Bank, Black Comb was observed elevated 31′ 31″; and the distance between the two stations is 121,028 feet. From these data we have to compute the mean refraction and the difference of altitude.

The height of the instrument at both stations was $5\frac{1}{2}$ feet. Hence if R″ denote the number of seconds in the arc equal to the radius, and x the correction for the height of the instrument, we have this proportion, $121028 : 5\cdot 5 :: R'' : x$; whence, since $R'' = 206{,}264\cdot 8$, x is found $= 9''$. Subtracting this from the seconds of observed depression, and adding it to the seconds of observed elevation, we find $d = 2944''$ and $-d' = 1900''$; whence $d + d' = 1044''$. Now allowing the length of a second of arc at the mean latitude to be $101\frac{1}{2}$ feet, the distance in seconds is $121{,}028 \div 101\frac{1}{2} = 1192$, or $C = 1192''$, and we have by formula (15) the mean refraction $\varrho = \frac{1}{2}\{C - (d + d')\} = 74''$, which is very nearly $\frac{1}{16}$th of the intercepted arc.

With this value of ϱ we obtain (16) $\varphi = -2422''$; whence, since $\sin. 1'' = \cdot 00000485$, we have for the difference of altitudes (17)

$$121028 \times -2422 \times \cdot 00000485 = -1422,$$

or the depression of Scilly Bank below Black Comb is 1422 feet. In the Survey, vol. iii. the altitudes of the two stations are stated to be respectively, Black Comb 1919 feet; Scilly Bank 500 feet; whence the difference is 1419 feet.

Authors referred to.

We have now explained, with as much detail as the limits which must be prescribed to the present article would permit, the methods of calculation by which the mutual distances of the several stations of an extensive survey, and their geographical co-ordinates, that is to say, their latitudes, longitudes, and altitudes, are deduced from the observations. These form the principal and essential objects of a trigonometrical survey of a country. There are however various other points of great importance connected with geodetical measurements, into which, in the present outline, it is impossible for us to enter; and particularly the methods of estimating the probable errors of the observations, and of the results deduced from them, and of applying these results to the determination of the form of the earth's surface in the country over which the operation extends. For information on these points, and indeed on all other questions relating to the higher geodesy, we refer the reader to the following works: Delambre, *Base du Système Métrique Décimal*, Paris, 1806–10; Gauss, *Supplementum Theoriæ Combinationis Observationum Erroribus minimis obnoxiæ*, Göttingen, 1828; Struve, *Breitengradmessung in den Ostseeprovinzen Russlands*, Dorpat, 1831; Bessel, *Gradmessung in Ostpreussen und ihre Verbindung mit Preussichen und Russichen Dreiecksketten*, Berlin, 1838; Puissant, *Traité de Géodésie*, 2d ed. Paris, 1822; and particularly the *Nouvelle Description Géométrique de la France*, Paris, 1832–40, by the last-named author,—a work which we could wish to see imitated in our own country. (s.)

TRIGONOMETRY.

Trigonometry.

1. **Trigonometry** is a branch of the mathematics which treats of the relations of the sides and angles of triangles, these being expressed by numbers. It is therefore a theory formed by the union of arithmetic and geometry, and it treats of a particular class of geometrical figures, namely, triangles.

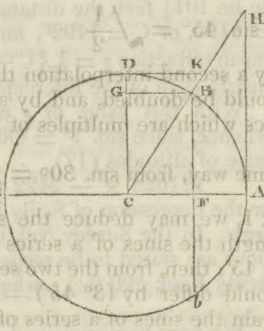
There are two kinds of triangles considered in trigonometry; *plane triangles*, and *spherical triangles*. The former are figures on a plane, and the latter on the surface of a sphere; hence we have *plane trigonometry* and *spherical trigonometry*, the principles of which will be explained in succession. In a triangle there are six things which may be considered, viz. the three sides, and the three angles. The main object of the theory is to give rules by which, when some of these are given, the others may be found.

2. The application of numbers to express the sides and angles of triangles has given rise to several terms which require to be defined before we proceed further.

Definitions.

I. Since angles at the centres of equal circles have to each other the same ratio as the arcs on which they stand, the arcs may be taken as representatives or *measures* of the angles to which they are proportional. Thus, let ACB be any angle contained by the lines AC, BC: if about C as a centre, with any distance or *radius* AC, a circle ABE be described, the arc AB, intercepted between the lines CA, CB, is the measure of the angle ACB.

Fig. 1.



II. The circumference of every circle is supposed to be divided into 360 equal parts called *degrees*, and again each degree is subdivided into 60 equal parts called *minutes*, and each minute into 60 equal parts called *seconds*; and an angle is said to be of as many degrees, minutes, seconds, &c. as there are degrees, and minutes, and seconds in its measure. The degrees in any arc or angle are indicated by the character ° placed over their number, the minutes by an accent ′, and the seconds by two accents ″. For example, an angle of 25 degrees 12 minutes and 14 seconds is expressed thus, 25° 12′ 14″.—A right angle is measured by one fourth part of the circumference, or a quadrant, and it contains 90°.

III. The *complement* of an arc or angle is the difference between it and a quadrant, or 90°. Thus, supposing AD to be a quadrant, the arc BD is the complement of the arc AB, and the angle BCD is the complement of the angle ACB.

IV. The *supplement* of an arc or angle is its difference from half the circumference, or 180°. Let ADE be a semicircle; the arc BDE is the supplement of the arc AB; and the angle BCE is the supplement of the angle ACB.

V. The *sine* of an arc or angle is the perpendicular drawn from one extremity of the arc, on the diameter, that passes through the other extremity. The line BF is the sine of the arc AB, or of the angle ACB.

VI. The *versed sine* is the segment of the diameter between its sine and the arc which measures the angle. The line AF is the versed sine of the arc AB, or the angle ACB, and EF the versed sine of the angle BCE.

VII. The *tangent* is a straight line that touches the arc at one end, and is limited at the other end by a straight line drawn from the centre of the circle through the other extremity of the arc. The line AH is the tangent of the arc AB, or the angle ACB.

VIII. The *secant* is the straight line drawn from the centre to the extremity of the tangent. The line CH is the secant of the arc AB, or angle ACB.

IX. The sine, tangent, and secant, of the complement of any arc or angle, are called by abbreviation its *cosine*, *cotangent*, and *cosecant*. Thus, BG = CF, the sine of the arc BD, is the cosine of the arc AB; and DK, the tangent of the arc BD, is the cotangent of AB; and CK, the secant of BD, is the cosecant of AB.

Trigonometrical Notation.

The sine of an angle whose measure is A, is expressed thus, *sin.* A; its cosine by *cos.* A; its tangent by *tan.* A; its cotangent by *cot.* A; its secant by *sec.* A; its cosecant by *cosec.* A; its versed sine by *ver. sin.* A; and its coversed sine by *co. ver. sin.* A.

The radius of a circle, when it is supposed the unit of numbers, requires no symbol: sometimes it is represented by the abbreviation *rad.* and also by the letter R.

3. There are two ways in which the theories of trigonometry have been established. One is by employing a process of reasoning purely geometrical, such as has been followed in our article Geometry. In this way the early writers on the subject constructed their treatises, and it served very well for plane triangles, but was less convenient for spherical triangles, by reason of the intricate diagrams required to represent circles lying in different planes; and also by the complicated relations of the things to be discussed, which could not easily be expressed by words. The second, which is the more convenient way, is by the symbolic reasoning of algebra. The section in Algebra on the Arithmetic of Sines is a specimen of this way of treating the subject; and it is worthy of remark, that the great extension that has been given to the subject is in no small degree due to the simple and convenient way of representing the sines and tangents, &c. of angles, by the abbreviations, *sin.* A, *tan.* A, &c. instead of referring to the geometrical lines themselves. As a consequence of this, geometrical constructions are avoided, and even diagrams are hardly necessary.

4. In applying the notation and doctrines of modern analysis to trigonometry, we regard the measures of angles, and their sines, tangents, &c. as endowed with the properties of variable quantity; in particular, we ascribe to them the quality of being *positive* or *negative*. The consequences of this hypothesis have been fully detailed in the *Arithmetic of Sines* (Algebra), to which we refer the reader. By this the properties of triangles are expressed by general formulæ, which comprehend all particular cases. This way of considering the numeral measures of trigonometrical lines has greatly simplified spherical trigonometry, and all applications of both trigonometries to astronomy and geodetical inquiries.

The Trigonometrical Table.

5. The basis of all trigonometrical calculations is a table which exhibits in parts of the radius the numeral values of the sine, tangent, and secant, of each arc in a series pro-

eding from 0 to a quadrant, the common difference of the rms being an angle of one minute, or some smaller angle.

The radius being considered as an unit, the sines are ex- essed as decimal fractions of that unit. The quadrant is nerally divided into degrees and minutes, this being suf- ient for most purposes; but tables have been calculated ich give the sines, and tangents, and secants, to every th second.

6. The Elements of Euclid show how to inscribe regular lygons of three, four, five, six, and fifteen sides in a circle. e sides of these polygons may be expressed in numbers d calculations derived from the geometrical constructions. ow, the side of an equilateral triangle in a circle, is the ord of 120°, which is twice the sine of 60°; and the side the inscribed square is the chord of 90°, which is twice the sine of 45°; and the side of the equilateral pentagon is the chord of 72°, which is twice the sine of 36°; and the e of the hexagon is the chord of 60°, which is twice the e of 30°; and the side of the quindecagon is the chord 24°, which is twice the sine of 12°. These sines may therefore be all deduced from the properties of polygons inscribed in a circle, as delivered in the Elements. And since the sum of the squares of the chord of an arc and the chord of its supplement is equal to the square of the dia- ter (Geom. 17 of 2 and 13 of 4), the chords of the sup- ments, and thence the sines of their halves, may be found. It was in this way the trigonometrical table was first constructed by the early mathematicians, Purbach, iller, Copernicus, G. Joachimus Rhæticus, and others. e theory of inscribed polygons was extended by Vieta into that of angular sections, chiefly with a view to the con- struction of the table. This has again been wrought up into the *Arithmetic* or *Calculus of Sines*, the formulæ of which afford great facility in the construction of the table. an example, we shall resolve this problem.

7. Problem. To find the sines of one fifth, two fifths, three fifths, and four fifths, of a quadrant, of which the sine is equal to the radius. Putting a to denote an arc of 18°, one fifth of the quadrant, we are to find the sines of a, $2a$, $4a$. Now, from the nature of the problem, we have these simple relations:

$$\text{Cos. } a = \sin. 4a,\ \cos. 2a = \sin. 3a,$$
$$\text{Cos. } 3a = \sin. 2a,\ \cos. 4a = \sin. a.$$

d by formula 3 of (E) art. 240, Algebra,

$$\text{Sin. } 2a = 2 \sin. a \cos. a,$$
$$\text{Sin. } 3a = 2 \sin. 2a \cos. a - \sin. a,$$
$$\text{Sin. } 4a = 2 \sin. 3a \cos. a - \sin. 2a,$$
$$\text{Sin. } 5a = 2 \sin. 4a \cos. a - \sin. 3a.$$

erefore
$$\text{Sin. } 2a = 2 \sin. a \sin. 4a,$$
$$\text{Sin. } 3a = 2 \sin. 2a \sin. 4a - \sin. a,$$
$$\text{Sin. } 4a = 2 \sin. 3a \sin. 4a - \sin. 2a,$$
$$\text{Sin. } 5a = 1 = 2 \sin. 4a \sin. 4a - \sin. 3a.$$

abridge, put $\sin. a = u$, $\sin. 2a = x$, $\sin. 3a = y$, $\sin. 4a$ z, and we have the following equations:

$$2uz = x \ldots\ldots\ldots\ldots\ldots\ldots\ldots A,$$
$$2xz = y + u \ldots\ldots\ldots\ldots\ldots\ldots B,$$
$$2yz = z + x \ldots\ldots\ldots\ldots\ldots\ldots C,$$
$$2zz = 1 + y \ldots\ldots\ldots\ldots\ldots\ldots D.$$

ese express symmetrical relations, which connect the ur sines u, x, y, z.

By subtracting A from C, and dividing the remainder by , we have

$$y - u = \tfrac{1}{2} \ldots\ldots\ldots\ldots\ldots\ldots\ldots (1).$$

d from B, A, D; $y + u = 2xz = 4uz^2 = 2u + 2uy$.
erefore $2uy = y - u = \frac{1}{2}$;

d hence, $(y+u)^2 = (y-u)^2 + 4uy = \dfrac{5}{4}$,

$$\text{and } y + u = \frac{\sqrt{5}}{2} \ldots\ldots\ldots\ldots\ldots\ldots (2).$$

We have now, by subtraction and addition from (1) and (2),

$$\sin. a = u = \frac{\sqrt{5}-1}{4},\ \sin. 3a = y = \frac{\sqrt{5}+1}{4}.$$

Now the arcs a and $4a$ being the complements of each other, also $3a$ and $2a$, and the sum of the squares of the sine and cosine being equal to the square of the radius, we have

$$\sin. 2a = x = \sqrt{(1-y^2)} = \frac{\sqrt{(10-2\sqrt{5})}}{4},$$
$$\sin. 3a = z = \sqrt{(1-u^2)} = \frac{\sqrt{(10+2\sqrt{5})}}{4}.$$

Our problem is now resolved.

8. We have found the sines of a series of arcs from 0 to 90°, viz. 18°, 36°, 54°, 72°, which differ by 18°. From these, the sines of a series whose terms differ by 9°, may be found by formulæ, which are modifications of formulæ (1), (2) of (P), article 249, Algebra, viz.

$$\sin. \tfrac{1}{2}(90° - a) = \sqrt{\frac{1-\sin. a}{2}},$$
$$\sin. \tfrac{1}{2}(90° + a) = \sqrt{\frac{1+\sin. a}{2}}.$$

The terms intermediate to those known are,

$$\sin. 9° = \sqrt{\frac{1-\sin. 72°}{2}},\ \sin. 63° = \sqrt{\frac{1+\sin. 36°}{2}},$$
$$\sin. 27° = \sqrt{\frac{1-\sin. 36°}{2}},\ \sin. 81° = \sqrt{\frac{1+\sin. 72°}{2}},$$
$$\sin. 45° = \sqrt{\frac{1}{2}}.$$

By a second interpolation the number of terms in the series would be doubled, and by a third, the sines of a series of arcs which are multiples of 2° 15′ would be found. In the same way, from $\sin. 30° = \frac{1}{2}$, $\sin. 60° = \frac{\sqrt{3}}{2}$, and $\sin. 90° = 1$, we may deduce the sines of 15°, 45°, 75°; and at length the sines of a series of arcs, which are multiples of 3° 45′; then, from the two series, another, the arcs of which would differ by (3° 45′) — (2° 15′) = 1° 30′ = 90′; and again the sines of a series of arcs differing by 45′. Indeed it was in this way the table was first formed.

9. When the sines of two thirds of the quadrant, that is, from 0 to 60°, are known, the sines of the remaining third can be readily found; for since $\sin. (a+b) = \sin. (a-b) + 2 \cos. a \sin. b$ (Algebra, art. 240), if we make $a = 60°$, then $\cos. a = \frac{1}{2}$, and $2 \cos. a = 1$, and we have $\sin. (60° + b) = \sin. (60° - b) + \sin. b$. By this formula the numbers in the table may be verified.

The radius being an unit, we have found that the semicircumference or arc of 180° = 3·1415926535 (Algebra, article 272). This number divided by 180 × 60 = 1080, gives the arc which measures an angle of one minute = ·0002908882; and since a small arc is nearly equal to its sine, we have sin. 1′ = ·0002908882 nearly. The accuracy of this may be verified by the formula

$$\sin. a = a - \frac{a^3}{6} + \frac{a^5}{120} -, \&c.\ (\text{Algebra, art. } 269).$$

The cosine of one minute is found from the sine by the formula $\cos. a = \sqrt{(1 - \sin.^2 a)}$, or otherwise, by the series

$$\cos. a = 1 - \frac{a^2}{2} + \frac{a^4}{24} -, \&c. = \cdot 9999999577.$$

Knowing now the sine and cosine of one minute, to find the sines of 2′, 3′, 4′, &c. we may proceed thus,—

$$\text{Sin. } 2' = 2 \cos. 1' \sin. 1',$$
$$\text{Sin. } 3' = 2 \cos. 1' \sin. 2' - \sin. 1',$$
$$\text{Sin. } 4' = 2 \cos. 1' \sin. 3' - \sin. 2',$$
$$\&c.$$

10. Since the results obtained by the successive opera-

Plane Trigonometry.

tions are only approximations, they will diminish in accuracy as we advance. We may however proceed otherwise thus. Find, as has been explained, a series of sines of arcs differing by 45′ from 0° to 60°; then fill up, by interpolation, the intervals thus: We have found (ALGEBRA, art. 239) $\sin.(a+b)+\sin.(a-b)=2\cos.b\sin.a$: instead of a write $x+h$, and instead of b write h, and we have

$$\sin.(x+2h)+\sin.x=2\cos.h\sin.(x+h).$$

$$\text{Now } \cos.h=1-\frac{h^2}{1\cdot2}+\frac{h^4}{1\cdot2\cdot3\cdot4}-\frac{h^6}{1\cdot2\cdot3\cdot4\cdot5\cdot6}, \text{ \&c.}$$

Put n to denote the series $h^2-\frac{h^4}{3\cdot4}+\frac{h^6}{3\cdot4\cdot5\cdot6}, -$ &c. and we have

$\sin.(x+2h)+\sin.x=2\sin.(x+h)-n\sin.(x+h)$;

and $\sin.(x+2h)=\sin.(x+h)+\{\sin.(x+h)-\sin.x\}-n\sin.(x+h)$. If h be an arc of one minute, then $h=\cdot0002908882$, and $n=\cdot0000000846$. Let x denote any angle, and suppose h to be one minute; the formula gives

$$\sin.(x+1')=\sin.x+\{\sin.x-\sin.(x-1')\}-n\sin.x,$$

$$\sin.(x+2')=\sin.(x+1')+\{\sin.(x+1')-\sin.x\}-n\sin.(x+1'),$$

$$\sin.(x+3')=\sin.(x+2')+\{\sin.(x+2')-\sin.(x+1')\}-n\sin.(x+2').$$

Thus, from the sines of two arcs $x-1'$ and x, which differ by $1'$, and the constant number $n=2(1-\cos.1')=(2\sin.30'')^2$, the sines of all angles or arcs exceeding x, and differing by $1'$, throughout the table, may be found. The most extensive table of sines in existence (which is yet in manuscript), was computed under the direction of the late M. Prony in this way. It gives the sines of all arcs in a series of which the common difference is one ten-thousandth part of a quadrant with twenty-five decimals.

11. The sines being found, the tangents and secants may be obtained, each by a single division from the formulæ

$$\tan.a=\frac{\sin.a}{\cos.a}, \quad \sec.a=\frac{1}{\cos.a}.$$

The tangents of the latter half of the quadrant may however be found by addition only from the formula

$$\tan.(45^\circ+a)=\tan.(45^\circ-a)+2\tan.2a,$$

which is a deduction from (4) of (O) ALGEBRA, art. 248; and the secants from this formula,

$$\sec.a=\tan.a+\tan.(45^\circ-\tfrac{1}{2}a), \text{ ALGEBRA, 249.}$$

12. With a table of sines, and tangents, and secants, the ordinary questions relating to triangles may be resolved by multiplication and division, but more expeditiously by logarithmic calculation; and therefore, in general, mathematical tables give only the logarithmic sines, tangents, and sometimes secants, which, however, may be readily found from the log. cosines.

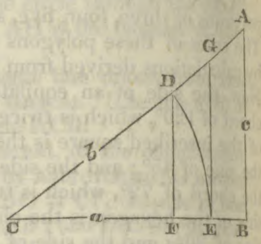
PART I.—PLANE TRIGONOMETRY.

13. In contemplating a plane triangle as a figure formed by three straight lines, we distinguish the sides of the triangle, the angles at their intersections, and the space or area which they comprehend. In trigonometry we abstract from the area, and consider only the sides and angles. There are in all six angles, viz. the three interior and their adjacent exterior angles. Each of the exterior is the sum of two interior angles, and of these any two determine the third; so that in fact the independent elements of a triangle are five, viz. its three sides, and any two of its three interior angles; and of these any three being given, the remaining two may be found.

14. The sides and angles are dissimilar in their nature, and therefore do not admit of being directly compared: the measures of angles, being arcs of a circle described with a given radius, are lines, and therefore expressible by the sides. It is however more convenient and easy to use the sines and tangents, &c. of angles than the angles themselves, in trigonometrical calculations, the rules of which are to be deduced from the following theorems.

THEOREM I. In any right-angled triangle, the radius is to the sine of either of the acute angles as the hypotenuse is to the side opposite that angle. (Fig. 2.)

Fig. 2.



Let ABC be a right-angled triangle, of which B is the right angle; about C, one of the acute angles, as a centre, with a radius equal to the radius in the tables, describe an arc DE as the measure of the angle C (Def. 1). Draw DF, the sine of the arc DE (Def. 5). The triangles CDF, CAB are manifestly equiangular, therefore their sides are proportionals; so that CD : DF = CA : AB, or (putting R to denote radius in the tables) R : sin. C = CA : AB.

Corollary 1. The radius is to the cosine of either of the oblique angles as the hypotenuse is to the side adjacent to that angle. For, to the radius CD, CF is the cosine of C, and CD : CF = CA : CB.

Corollary 2. Assuming that CD = R = 1, we have

1 : sin. C = CA : AB; and 1 : cos. C = CA : CB.

Therefore, supposing the sides of the triangle expressed by numbers,

$$\sin.C=\frac{AB}{CA}, \text{ and } \cos.C=\frac{CB}{CA}.$$

THEOREM II. In any right-angled triangle, the radius is to the tangent of either of the oblique angles as the adjacent side to the opposite side. (Fig. 2.)

At the point E, one extremity of the arc DE which measures the angle C, draw EG perpendicular to CB; then to the radius CE, EG is the tangent of the angle C (Def. 7). Now the triangles CEG, ABC being similar, CE : EG = CB : BA, or R : tan. C = CB : BA.

Corollary 1. The radius is to the secant of either of the oblique angles as the adjacent side to the hypotenuse; for CG is the secant of the angle C (Def. 8); and CE : CG = CB : CA, or R : sec. C = CB : CA.

Corollary 2. Assuming the radius = 1, then

$$\tan.A=\frac{BA}{CB}, \text{ and } \sec.C=\frac{CA}{CB}.$$

Corollary 3. In any triangle, if a perpendicular be drawn from any one of the angles to the opposite side, the segments of that side are to one another as the tangents of the parts into which the opposite angle is divided by the perpendicular.

Fig. 3.

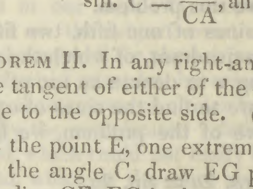


Fig. 4.

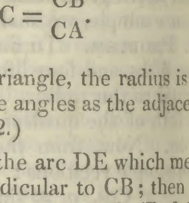
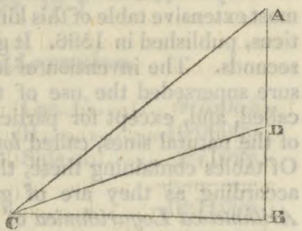


For in the triangles ADB, ADC,
BD : DA = tan. BAD : R; and DA : DC = R : tan. CAD.
Therefore, *ex æquali*, BD : DC = tan. BAD : tan. CAD.

heorem III. In any right-angled triangle, the sum of the hypotenuse and one side is to their difference, as the square of the radius to the square of the tangent of half the contained angle.

Fig. 5.



Let ABC be any right-anged triangle; draw CD bisecting the angle C.

y Geom. 19, 4,

$$CA : CB = AD : BD = AB - BD : BD.$$

erefore, by composition, and r. 3 of Theor. II. of Trig.

$$CA + CB : CB = AB : BD = \text{tan. } C : \text{tan. } \tfrac{1}{2}C.$$

$$\text{Now } CB : BA = R : \text{tan. } C,$$

erefore $CA + CB : BA = R : \text{tan. } \frac{1}{2}C$,

and $(CA + CB)^2 : BA^2 = R^2 : \text{tan.}^2 \frac{1}{2}C$.

Now $BA^2 = CA^2 - CB^2 = (CA + CB)(CA - CB)$ (eom. 9 and 13 of 4),

erefore

$$A + CB)^2 : (CA + CB)(CA - CB) = R^2 : \text{tan.}^2 \tfrac{1}{2}C,$$

$$\text{and } CA + CB : CA - CB = R^2 : \text{tan.}^2 \tfrac{1}{2}C.$$

The first two of these propositions are alone sufficient for t e resolution of all the cases of right-angled triangles; the t rd, which is not commonly given in our books on trigo- metry, is however important, because when the hypo- t use and a side are given, by its application the same lo- rithms serve for finding the remaining side and the tan- nt of half the opposite angle.

15. It has been found conducive to brevity and perspi- ity, to represent the parts of a triangle, each by a single ter: therefore, in any triangle ABC, we shall, in what lows, employ that notation to denote the sides and angles follows. (See figures 2, 3, 4.)

$$\text{The sides, } BC = a,\ AC = b,\ AB = c;$$

$$\text{the angles, } BAC = A,\ ABC = B,\ ACB = C.$$

It will also be sometimes convenient to express ratios by ctions, the numerators of which are the antecedents, and e denominators the consequents, so that the expressions

$: B = C : D$, and $\frac{A}{B} = \frac{C}{D}$, are to be regarded as identical.

heorem IV. The sides of any plane triangle are to one another as the sines of the opposite angles. (Figs. 3 and 4.)

In the triangle ABC, draw AD perpendicular to BC; en, employing the premised notation, that is, denoting e sides by a, b, c, and opposite angles by A, B, C,

$$b : AD = R : \text{sin. } C;\ \text{and } AD : c = \text{sin. } B : R;$$

therefore, *ex æquali*, inversely, $b : c = \text{sin. } B : \text{sin. } C$.

heorem V. The sum of the sides of any plane triangle is to the difference, as the tangent of half the sum of the opposite angles is to the tangent of half their difference.

Continuing the same notation, we have found that

$$b : c = \text{sin. } B : \text{sin. } C;$$

erefore $b + c : b - c = \text{sin. } B + \text{sin. } C : \text{sin. } B - \text{sin. } C$.

Now (Algebra, 247, M),

$$\text{n. } B + \text{sin. } C : \text{sin. } B - \text{sin. } C = \text{tan. } \tfrac{1}{2}(B + C) : \text{tan. } \tfrac{1}{2}(B - C);$$

erefore, $b + c : b - c = \text{tan. } \frac{1}{2}(B + C) : \text{tan. } \frac{1}{2}(B - C)$.

Corollary. Since $B + C = 180° - A$, and therefore

$$\tfrac{1}{2}(B + C) = 90° - \tfrac{1}{2}A,$$

therefore $b + c : b - c = \text{cot. } \frac{1}{2}A : \text{tan. } \frac{1}{2}(B - C)$.

heorem VI. In any triangle, the cosine of half the difference of any two of its angles is to the cosine of half their sum, as the sum of the sides opposite these angles is to the remaining side. And the sine of half the difference of the angles is to the sine of half their sum, as the difference of the opposite sides to the remaining side.

Again, denoting the sides by a, b, c, and opposite angles by A, B, C,

$$\text{Because sin. } A : \text{sin. } C = a : c,$$

$$\text{and } \text{sin. } B : \text{sin. } C = b : c;$$

$$\text{therefore sin. } A + \text{sin. } B : \text{sin. } C = a + b : c,$$

$$\text{also } \text{sin. } A - \text{sin. } B : \text{sin. } C = a - b : c.$$

Now, $\text{sin. } A + \text{sin. } B = 2 \text{ sin. } \frac{1}{2}(A + B) \text{ cos. } \frac{1}{2}(A - B)$ (Algebra, 240),

and $\text{sin. } A - \text{sin. } B = 2 \text{ cos. } \frac{1}{2}(A + B) \text{ sin. } \frac{1}{2}(A - B)$,

and $\text{sin. } C = \text{sin. } (A + B) = 2 \text{ sin. } \frac{1}{2}(A + B) \text{ cos. } \frac{1}{2}(A + B)$ (Algebra, 245);

therefore

$\text{sin. } A + \text{sin. } B : \text{sin. } C = \text{cos. } \frac{1}{2}(A - B) : \text{cos. } \frac{1}{2}(A + B)$,

and

$\text{sin. } A - \text{sin. } B : \text{sin. } C = \text{sin. } \frac{1}{2}(A - B) : \text{sin. } \frac{1}{2}(A + B)$;

$$\text{hence cos. } \tfrac{1}{2}(A - B) : \text{cos. } \tfrac{1}{2}(A + B) = a + b : c,$$

$$\text{and } \text{sin. } \tfrac{1}{2}(A - B) : \text{sin. } \tfrac{1}{2}(A + B) = a - b : c;$$

Theorem VII. If a perpendicular be drawn from an angle of a triangle on the opposite side, dividing it into two segments, the sum of these segments is to the sum of the sides as the difference of the sides to the difference of the segments.

In the triangle ACB, $AC^2 = AD^2 + CD^2$, and $AB^2 = AD^2 + DB^2$, therefore $AC^2 - AB^2 = CD^2 - BD^2$. Now $AC^2 - AB^2 = (AC + AB)(AC - AB)$, and $CD^2 - BD^2 = (CD + BD)(CD - BD)$ (Geometry, 12, 4);

therefore $(AC + AB)(AC - AB) = (CD + BD)(CD - BD)$,

$$\text{and } CD + BD : AC + AB = AC - AB : CD - BD.$$

Theorem VIII. In any plane triangle, the excess of the sum of the squares of two sides which contain an angle above the square of the third side, is to twice the rectangle contained by the sides about the angle, as the cosine of the angle is to radius. (Figs. 3 and 4.)

In the triangle ABC, draw AD perpendicular to BC, we have, by Geometry, 14, 4, and Cor. 2, Theorem I., of this,

$$c^2 = a^2 + b^2 - 2a \times CD, \text{ and } CD = b\,\frac{\text{cos. } C}{R};$$

$$\text{therefore } c^2 = a^2 + b^2 - 2ab\,\frac{\text{cos. } C}{R},$$

$$\text{and } \frac{a^2 + b^2 - c^2}{2ab} = \frac{\text{cos. } C}{R};$$

$$\text{therefore } a^2 + b^2 - c^2 : 2ab = \text{cos. } C : R.$$

We have, in the diagram, made the angle C acute, but the proposition is equally true when C is an obtuse angle; because, when C changes from *acute* to *obtuse*, the sign of the cosine of the angle changes from + to —.

Theorem IX. In any triangle, the rectangle contained by two sides is to the rectangle contained by half the perimeter and the excess of half the perimeter above the base, as the square of the radius to the square of the cosine of half the angle contained by the sides.

It has been found that a, b, c, being the sides of a triangle, and A the angle contained by b and c, then, Theorem VIII.,

$$\frac{\text{cos. } A}{R} = \frac{b^2 + c^2 - a^2}{2bc}.$$

To the first of these equals add $\frac{R}{R} = 1$, and to the second, $\frac{2bc}{2bc} = 1$; then

$$\frac{R + \text{cos. } A}{R} = \frac{b^2 + 2bc + c^2 - a^2}{2bc} = \frac{(b + c)^2 - a^2}{2bc}.$$

Plane Trigonometry.

Now $\frac{\mathrm{R} + \cos.\ \mathrm{A}}{\mathrm{R}} = \frac{2 \cos.^2 \frac{1}{2}\mathrm{A}}{\mathrm{R}^2}$ (ALGEBRA, 249, P), and $(b + c)^2 - a^2 = (a + b + c)(b + c - a)$. Put $s = \frac{1}{2}(a + b + c)$, then $b + c - a = a + b + c - 2a = 2(s - a)$; we have now $(b + c)^2 - a^2 = 4s(s - a)$, and, by substituting, $\frac{\cos.^2 \frac{1}{2}\mathrm{A}}{\mathrm{R}^2} = \frac{s(s - a)}{bc}$, and

$bc : s(s - a) = \mathrm{R}^2 : \cos.^2 \frac{1}{2}\mathrm{A}$.

THEOREM X. In any triangle, the rectangle contained by two sides is to the rectangle contained by the excesses of half its perimeter above these sides, as the square of the radius to the square of the sine of half the angle contained by the sides.

Supposing, as in last proposition, that b and c are the sides about an angle A, and a the side opposite to a, we have, by Theorem IX.

$$\frac{\cos.\ \mathrm{A}}{\mathrm{R}} = \frac{b^2 + c^2 - a^2}{2bc}.$$

Subtract the first of these equals from $\frac{\mathrm{R}}{\mathrm{R}} = 1$, and the second from $\frac{2bc}{2bc} = 1$, and we have

$$\frac{\mathrm{R} - \cos.\ \mathrm{A}}{\mathrm{R}} = \frac{2bc - b^2 - c^2 + a^2}{2bc} = \frac{a^2 - (b - c)^2}{2bc}.$$

Now $\frac{\mathrm{R} - \cos.\ \mathrm{A}}{\mathrm{R}} = \frac{2 \sin.^2 \frac{1}{2}\mathrm{A}}{\mathrm{R}^2}$ (ALGEBRA, 249, P),

and $a^2 - (b - c)^2 = (a + b - c)(a - b + c)$.

Put $s = \frac{1}{2}(a + b + c)$,

then $a + b - c = a + b + c - 2c = 2s - 2c$,

and $a - b + c = a + b + c - 2b = 2s - 2b$;

we have now $a^2 - (b - c)^2 = 4(s - b)(s - c)$,

and $\frac{\sin.^2 \frac{1}{2}\mathrm{A}}{\mathrm{R}^2} = \frac{(s - b)(s - c)}{bc}$,

and $bc : (s - b)(s - c) = \mathrm{R}^2 : \sin.^2 \frac{1}{2}\mathrm{A}$.

THEOREM XI. In any triangle, the rectangle contained by half the perimeter, and its excess above the base, is to the rectangle contained by the excesses of half the perimeter above the two sides, as the square of the radius to the square of the tangent of half the angle contained by the sides.

As in the two preceding theorems, putting b and c for the sides about the angle A, and a for the opposite side, and $s = \frac{1}{2}(a + b + c)$, we have found that

$$s(s - a) : bc = \cos.^2 \tfrac{1}{2}\mathrm{A} : \mathrm{R}^2,$$

and $bc : (s - b)(s - c) = \mathrm{R}^2 : \sin.^2 \frac{1}{2}\mathrm{A}$;

therefore, *ex æquali*,

$$s(s - a) : (s - b)(s - c) = \cos.^2 \tfrac{1}{2}\mathrm{A} : \sin.^2 \tfrac{1}{2}\mathrm{A}.$$

But $\cos.^2 \frac{1}{2}\mathrm{A} : \sin.^2 \frac{1}{2}\mathrm{A} = \mathrm{R}^2 : \tan.^2 \frac{1}{2}\mathrm{A}$;

therefore $s(s - a) : (s - b)(s - c) = \mathrm{R}^2 : \tan.^2 \frac{1}{2}\mathrm{A}$.

SCHOLIUM. Since we have

$$\frac{\tan.^2 \frac{1}{2}\mathrm{A}}{\mathrm{R}^2} = \frac{(s - b)(s - c)}{s(s - a)} = \frac{1}{(s - a)^2} \cdot \frac{(s - a)(s - b)(s - c)}{s},$$

let us put M to denote the expression $\sqrt{\frac{(s - a)(s - b)(s - c)}{s}}$, and we have $\frac{\tan.\ \frac{1}{2}\mathrm{A}}{\mathrm{R}} = \frac{\mathrm{M}}{s - a}$. We have like expressions for the angles B, C, and, on the whole,

$$\tan. \tfrac{1}{2}\mathrm{A} = \frac{\mathrm{M}}{s - a}\mathrm{R},\ \tan. \tfrac{1}{2}\mathrm{B} = \frac{\mathrm{M}}{s - b}\mathrm{R},\ \tan. \tfrac{1}{2}\mathrm{C} = \frac{\mathrm{M}}{s - c}\mathrm{R}.$$

This seems to be the most convenient formula for finding the angles of a triangle when the sides are given.

16. Having laid down principles, we are next to apply them to trigonometrical calculation. The foundation, as has been already observed, is a table which shows, in parts of the radius, the lengths of the sine, and tangent, and secant, to every minute or smaller division of the quadrant. The most extensive table of this kind is that of G. Joachimus Rhæticus, published in 1596. It gives the sines, &c. to every ten seconds. The invention of logarithms has in a great measure superseded the use of the *natural sines*, as they are called, and, except for particular purposes, the logarithms of the natural sines, called *logarithmic sines*, only are used. Of tables containing these, there are innumerable varieties, according as they are of greater or less extent. The *Arithmetica Logarithmica* of Briggs, published in 1628, by Adrian Vlacq, in two folio volumes, is the most extensive. His tables give the logarithms of 100,000 numbers, and logarithmic sines and tangents to every ten seconds and to ten places of decimals. Hutton's Tables give the natural sines, and tangents, and secants; also their logarithms to every minute and to seven figures. Callet's *Tables Portatives* give the logarithmic sines and tangents to every ten seconds; and Taylor's Tables, in a large quarto, give the same to every second. For general use, Callet's are the most convenient. Tables which give the logarithms of numbers and sines, &c. to six, and even to five figures, are also useful. Of the former, we recommend Tables of six-figure Logarithms, superintended by Richard Farley of the Nautical Almanac Office (printed for Longman and Co. 1840); and of the latter, Tables of Logarithms, under the superintendence of the Society for the Diffusion of Useful Knowledge (Taylor and Walton, 1839). Those who perform many calculations find it convenient to have tables of different extent. The size of our work, and the form of its pages, make it quite unsuitable for a useful logarithmic table, which should be as portable as it can be made. Accordingly we have given none.

17. It is customary to treat first of right-angled triangles, and next of such as have all their angles oblique.

RIGHT-ANGLED PLANE TRIANGLES.

These form four distinct cases. Adhering to the notation premised in article 15, we shall denote the hypotenuse by the letter b, the sides about the right angle by a and c, and the opposite angles by A and C. (See fig. 2.)

CASE I. Given the side a, and either of the acute angles A, C, and consequently (GEOMETRY, 24, 1) both; to find the hypotenuse b and remaining side c.

Solution. R : tan. C = side a : side c;
R : sec. C = side a : hyp. b : or cos. C : R = side a : hyp. b.

CASE II. Given the hypotenuse b, and either of the acute angles A, C; to find the sides a, c about the right angle B.

Solution. R : cos. C = hyp. b : side a,
R : sin. C = hyp. b : side c.

CASE III. Given the sides a, c about the right angle B; to find the angles A, C, and hypotenuse b.

Solution. Side a : side c = R : tan. C,
cos. C : R = side a : hyp. b.

The hypotenuse C may be found independently of the angles by the formula $b = \sqrt{(a^2 + c^2)}$ (GEOMETRY, 13, 4). The angle A is found from C, as above.

CASE IV. Given the hypotenuse b, and a side a; to find the angles A, C, and side c.

Solution. Hyp. b : side a = R : cos. C;
or thus, $b + a : b - a = \mathrm{R}^2 : \tan.^2 \frac{1}{2}\mathrm{C}$;
then side $c = \sqrt{\{(b + a)(b - a)\}}$.

The advantage of this solution is, that the same logarithms, viz. of $b + a$ and $b - a$, serve to find the side c and angle C.

Plane Trigonometry.

18. Examples of the solution of right-angled triangles.

$$\text{Case I. Given}\left\{\begin{array}{l}\text{side } a = 514,\\ \text{angle C} = 55° \ 44',\end{array}\right.\quad\left.\begin{array}{l}\\ \\ \text{and therefore angle A} = 34 \ \ 16.\end{array}\right\}\begin{array}{l}\text{Required side } c\\ \text{and hypot. } b.\end{array}$$

Calculation by Logarithms.

Side *a*..............	2·49693	Sin. C..........	9·94506
R.....................	10·00000	Hyp. *b*.........	2·82217
Sin. A = 28° 13⅓′	9·67476	Side *c* 585·1	2·76723

This case may be resolved also thus, by Theor. III.

b + *a*.....................	2·99034	*b* + *a*......	2·99034
b — *a*.....................	2·54407	*b* — *a*......	2·54407
R^2.........................	20·00000		2)5·53441
Tan.² ½C..............	2)19·55373	*c* = 585·1	2·76720
Tan. ½ C = 30° 53⅓′	9·77686		
C = 61 46⅔			

This second solution, although not given in our books of igonometry, is better than the first, because the two ings sought are obtained by the same logarithms, and inependently of each other.

No notice is here taken of geometrical constructions of e cases by scales. We however recommend that the stuent construct all the cases geometrically, and refer him the article NAVIGATION for examples and practical diections.

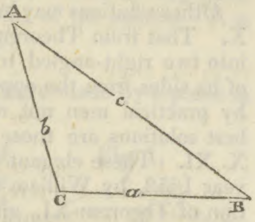
OBLIQUE-ANGLED TRIANGLES.

19. The three angles of any plane triangle being equal to two right angles (GEOMETRY, 24, 1), when two of them are given, the third is also given.

There are four cases of oblique-angled triangles.

CASE I. When a side *a*, and two angles B, C, and consequently the third angle A, which is the supplement of B + C, are given; to find the sides *b*, *c*.

Fig. 6.



SOLUTION. Sin. A : sin. B = *a* : *b*
Sin. A : sin. C = *a* : *c* } Th. IV.

CASE II. Two sides *b*, *c*, and an angle C opposite to one of them, are given; to find the other two angles A, B, and the remaining side *a*. (Fig. 7.)

SOLUTION. *Side c* : *side b* = *sin.* C : *sin.* B (Th. IV.)
When B is found, A = 180° — (B + C) is known; and sin. C : sin. A = side *c* : side *a*.

Since any two angles, which make together two right angles, have the same sine, and the angle B in this case is to be found by its sine only being known; it will have two distinct values, viz. B, and B′ = 180° — B. The angle A may also have two values, A = 180° — (B + C), and A′ = 180° — (B′ + C). Thus there will be two triangles ABC, AB′C, which alike satisfy the conditions of the data. It must however be considered that the three angles of a triangle cannot exceed two right angles, therefore if C be an obtuse angle, B can only be an acute angle, because a triangle cannot have two obtuse angles. Farther, if the side *c* opposite to the given angle C be greater than *b*, in this case B can have but one value; for when *c* is greater than *b*, then C is greater than either of the values of B, one of which is 180 — B (GEOMETRY, 13, 1), and C + B will be greater than 180°, which is impossible (24, 1).

Because $\frac{c}{b} = \frac{\text{sin. C}}{\text{sin. B}}$, and sin. B cannot exceed the radius, therefore $\frac{c}{b}$ cannot be less than $\frac{\text{sin. C}}{\text{R}}$; and unless the data satisfy this condition, the solution will be impossible.

CASE II. Two sides *b*, *c*, and the angle A between them, are given; to find the angles B, C, and the remaining side *a*.

SOLUTION. When A is given, B + C its supplement is given; then $b + c : b - c = \text{tan.} \frac{1}{2}(B + C) : \text{tan.} \frac{1}{2}(B - C)$. (Theorem V.)
Thus $\frac{1}{2}(B - C)$ becomes known, and $B = \frac{1}{2}(B + C) + \frac{1}{2}(B - C)$, also $C = \frac{1}{2}(B + C) - \frac{1}{2}(B - C)$, are known. All the angles of the triangle being known, and two of its sides; the remaining side may be found in two ways by Case I., or better by either of these proportions,

$$\left.\begin{array}{l}\text{Cos. } \frac{1}{2}(B - C) : \text{cos. } \frac{1}{2}(B + C) = b + c : a,\\ \text{Sin. } \frac{1}{2}(B - C) : \text{sin. } \frac{1}{2}(B + C) = b - c : a.\end{array}\right\}\text{Theor. VI.}$$

If both be used, the results will verify each other. The side *a* may also be found by Theorem III.

CASE IV. The three sides *a*, *b*, *c* are given; to find the three angles.

SOLUTION. Find $s = \frac{1}{2}(a + b + c)$,

$$\text{and } M = \sqrt{\left\{\frac{(s - a)(s - b)(s - c)}{s}\right\}}.$$

Then, by Theorem XI., $\text{tan. } \frac{1}{2}A = \frac{M}{s - a} \cdot R$, $\text{tan. } \frac{1}{2}B = \frac{M}{s - b} \cdot R$, $\text{tan. } \frac{1}{2}C = \frac{M}{s - c} \cdot R$.

Plane Trigonometry.

By this rule, the values of the three angles may be readily found, and also a verification of the calculation, because the sum of the halves of the angles must make ninety degrees.

Other solutions may be had from Theorems VII. VIII. IX. X. That from Theorem VII. (which resolves the triangle into two right-angled triangles by a perpendicular on one of its sides from the opposite angle) is very generally used by practical men not much versed in theory; but the best solutions are those which follow from Theorems IX. X. XI. These elegant formulæ were first found about the year 1653, by William Purser of Dublin. The modification of Theorem XI., given here as a practical rule, is the best method we know for resolving this case.

Examples of Oblique-angled Triangles.

$$\text{CASE I. Given}\left\{\begin{array}{l}\text{side } a = 575\\ \text{angle B} = 63° \ 48'\\ \text{angle C} = 49 \ \ 25\end{array}\right\}\text{Required the sides } b,\ c.$$

and therefore angle A = 66 47

Sin. A	9·96333	Sin. A	9·96333
Sin. B	9·95292	Sin. C	9·88051
Side a	2·75967	Side a	2·75967
	12·71259		12·64018
Side b = 561·4	2·74926	Side c 475·2	2·67685

$$\text{CASE II. (Fig. 7.) Given}\left\{\begin{array}{l}\text{side } b = 345\\ \text{side } c = 232\\ \text{angle C} = 37° \ 20'\end{array}\right\}\text{Required angles A, B, and side } a.$$

Side c	2·36549	From	180° 0′
Side b	2·53782	subtract B + C =	101 44
Sin. C	9·78280	angle CAB =	78 16
	12·32062	From	180 0
Sin. B = 64° 24′ or sin. B′ = 115 36	9·95513	subtract B′ + C =	152 56
		angle CAB′ =	27 4

In this example the angle A has two distinct values, from which we shall find two values of BC = a, and B′C = a'.

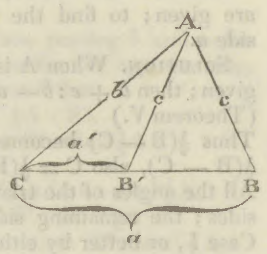


Fig. 7.

To find BC.		To find B′C.	
Sin. C	9·78280	Sin. C	9·78280
Sin. BAC	9·99083	Sin. B′AC	9·65804
Side c	2·36549	Side c	2·36549
	12·35632		12·02353
Side BC = a	2·57352	Side B′C = a'	2·24073
= 374·6		= 174·1	

Example 2. In a plane triangle, there are given two sides, 532 and 358, and the angle opposite to the former, 107° 40′; to find the remaining angles and side.

In this example, the things required have each only one value. The angles will be found 39° 53′ and 32° 27′, and the remaining side 299·6.

$$\text{CASE III. Given}\left\{\begin{array}{l}\text{side } b = 1230\\ \text{side } c = 870\\ \text{angle A} = 105°\end{array}\right\}\text{Required angles B, C, and side } a.$$

$b + c = 2100$, $b - c = 360$, $\text{B} + \text{C} = 180° - \text{A} = 75°$,

$\tfrac{1}{2}(\text{B} + \text{C}) = 37° \ 30'$

$b + c$	3·32222	Cos. $\tfrac{1}{2}$(B — C)	9·99628
$b - c$	2·55630	Cos. $\tfrac{1}{2}$—(B + C)	9·89947
Tan. $\tfrac{1}{2}$(B + C) = 37° 30′	9·88498	$b + c$	3·32222
	12·44128		13·22169
Tan. $\tfrac{1}{2}$(B — C) = 7 29$\tfrac{2}{3}$	9·11906	a = 1680·4	3·22541
B = 44 59$\tfrac{2}{3}$			
C = 30 0$\tfrac{1}{3}$			

As a verification, a may be found from this other proportion:

$$\text{Sin. } \tfrac{1}{2}(\text{B} - \text{C}) : \text{sin. } \tfrac{1}{2}(\text{B} + \text{C}) = b - c : a.$$

The side a may also be found by Case I. in two ways, because all the angles and two sides are known.

20. In all the preceding operations, the logarithm of the fourth term of each proportion has been found by subtracting the logarithm of the first term from the sum of the logarithms of the second and third. Now, in every case, when one number a is to be subtracted from another number b, we may obtain the result required by adding the difference between a, and n any number, and then subtracting the number n from the result. Thus, instead of subtracting 7 from 12, we may add 3, the difference between 7 and 10, to 12, and then rejecting 10 from 15, the sum, obtain 5 for the difference between 12 and 7. The reason of this may be easily understood, and it is evident from algebraic subtraction; for $b - a = b + (n - a) - n$. When a, the number to be subtracted, is less than 10, then n is conveniently assumed = 10, and when a is between 10 and 20, then n may be taken = 20. Thus, if 17 is to be subtracted from 63, the remainder, 46, is found by adding 3 (= 20 — 17) to 63, and rejecting 20 from the sum.

Hence, in trigonometrical calculation, instead of subtracting the log. of the first of four proportionals from the sum of the logs. of the second and third in order to obtain the log. of the fourth term, we may add into one sum the logs. of the second and third terms, and the difference between the log. of the first and 10, and rejecting, mentally, 10 from the sum, we have what is required.

The difference between a logarithm and 10·00000, &c. is called the *arithmetical complement* of that logarithm; and it is most readily obtained by subtracting every figure, beginning at the left hand, from 9, and the last significant figure from 10; thus, the arithmetical complement of 2·73651 is 7·26349, and the arithmetical complement of 9·78460 is 0·21540. By the introduction of the arithmetical complements of logarithms, fewer figures are required in calculations; for, with a little practice, it will be found as easy to read the arithmetical complements of logarithms from the table as the logarithms themselves. We have now this rule for finding a fourth proportional to three given numbers. Add together the arithmetical complement of the logarithm of the first term, and the logarithms of the second and third terms; the sum is the logarithm of the fourth.

As an example, take the above proportion:

$$\text{Sin. } \tfrac{1}{2}(\text{B} - \text{C}) : \text{sin. } \tfrac{1}{2}(\text{B} + \text{C}) = b - c : a.$$

Sin. $\tfrac{1}{2}$(B — C) arith. comp.,	0·88465
Sin. $\tfrac{1}{2}$(B + C)	9·78445
$b - c$	2·55630
a = 1680·4	3·22540

We have the same value of a as above.

C SE IV. Given $\left\{\begin{array}{l}\text{side } a = 800\\ \text{side } b = 562\\ \text{side } c = 320\end{array}\right\}$ Required the angles A, B, C.

$$\begin{array}{rll}
 & \underline{}\ 2)1682 & \\
 & & \text{Logs.}\\
s=\tfrac{1}{2}(a+b+c)= & 841 & 7{\cdot}07520 \text{ Ar. comp. log.}\\
s-a= & 41 & 1{\cdot}61278\\
s-b= & 279 & 2{\cdot}44560\\
s-c= & 521 & 2{\cdot}71684\\
 & & \overline{2)3{\cdot}85042}\\
 & \text{M}\ldots\ldots\ldots\ldots & 1{\cdot}92521\\
 & \text{R}\ldots\ldots\ldots\ldots & 10{\cdot}00000\\
 & \text{RM}\ldots\ldots & \overline{11{\cdot}92521}
\end{array}$$

$$\begin{array}{lll}
\dfrac{\text{RM}}{s-a}=\tan.\tfrac{1}{2}\text{A} & 10{\cdot}31243 & \tfrac{1}{2}\text{A}=64^\circ\ \ 1'\ 55''\\
\dfrac{\text{RM}}{s-b}=\tan.\tfrac{1}{2}\text{B} & 9{\cdot}47961 & \tfrac{1}{2}\text{B}=16\ \ 47\ \ 23\\
\dfrac{\text{RM}}{s-c}=\tan.\tfrac{1}{2}\text{C} & 9{\cdot}20837 & \tfrac{1}{2}\text{C}=\ 9\ \ 10\ \ 41\\
 & \text{Verification} & \overline{89\ \ 59\ \ 59.}
\end{array}$$

H nce the angles come out $A = 128^\circ\ 3'\ 50''$, $B = 33^\circ\ 34'\ 46''$, $C = 18^\circ\ 21'\ 22''$. T e verification shows the correctness of the result.

Various applications of trigonometry have been given in M NSURATION and NAVIGATION; to these we refer the r der for more examples in the calculation of triangles.

PART II.—SPHERICAL TRIGONOMETRY.

1. In our treatise on GEOMETRY we have defined a *p ramid* (Sect. xi. Def. 6). The most simple solid of this k d is the *triangular* pyramid, or *tetraedron*, contained by f r plane triangles, or *faces*, each of which has a side comm n with the other three. The angles of these form four s d angles. Each of the solid angles presents for our cons eration six plane angles; namely, the three angles about t solid angle, and the three angles made by the planes of t faces, which are so related, that any three of them being g en, the other three may be found. The investigation of f mulæ which furnish rules by which this may be accomp shed, forms the object of what is to follow.

2. In the calculus of sines, the things considered are plane a gles. If two of these be inward angles of a triangle, and t third the outward and opposite angle, our formula for t sines, tangents, &c. of the sum and difference of two a gles (ALGEBRA) will express relations among the angles o a plane triangle. We are now to investigate formulæ a logous to these, which shall involve the angles of a pyram d. Although the calculus which treats of angles made b straight lines in a plane may be established independently o a circle, yet it is conducive to perspicuity to employ arcs o circles as the measures of angles. This has led to the m asuring of the angles of a pyramid by arcs of circles on t surface of a sphere whose centre is the vertex; then t angles made by the planes of its faces will be shown by the a gles contained by tangents to the circles at their points o intersection.

3. In treating of spherical trigonometry, we shall begin b explaining some properties of the sphere which depend o principles purely geometrical.

DEFINITIONS.

I. A *sphere* is a solid figure generated by the revolution o a semicircle about a diameter which remains unmoved.

Spherical Trigonometry.

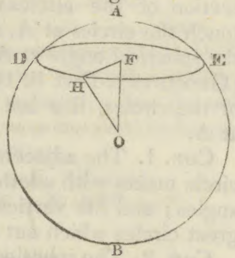
II. The diameter about which the semicircle turns, is the *axis* of the sphere; and the point which is the middle of that diameter is the *centre* of the sphere.

III. A straight line drawn from the centre to any point in the surface of a sphere, is a *radius* of the sphere. It is evident that all the radii are equal.

THEOREM I. Every section of a sphere made by a plane is a circle.

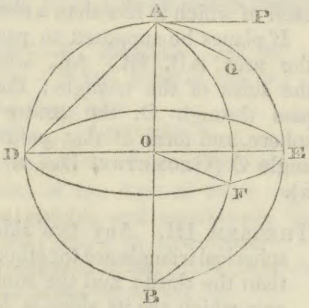
Let ADBE be a sphere, and DHE the curve line which is the common section of its surface and any plane. From O, the centre of the sphere, draw OF perpendicular to the plane DHE, and draw FH to any point in the curve DHE and join OH. In the triangle OFH, the angle OFH is a right angle; therefore $FH = \surd(OH^2 - OF^2)$. Now the lines OH and OF are invariable for all points in the curve DHE, therefore FH is invariable, and the curve DHE is the circumference of a circle whose radius is FH.

Fig. 1.



DEF. IV. The common section of a sphere and any plane that passes through its centre, is a great circle of the sphere. Let ADBE be a sphere whose centre is O; the circle DFE, in which any plane passing through O meets the sphere, is a great circle.

Fig. 2.



COR. 1. All great circles of the sphere are equal; and any two great circles mutually bisect each other.

COR. 2. A great circle may pass through any two assigned points on a sphere, which are not the extremities of a diameter. For if straight lines be drawn from the centre to the points, a plane may pass along these lines, and only one plane, whose common section with the sphere will be a great circle.

DEF. V. The pole of a great circle is a point on the surface of the sphere, from which all straight lines drawn to the circumference of the circle are equal.

Let DFE be a great circle, and O its centre; take D and F any points in its circumference, join OD, OF, and draw OA perpendicular to the plane of the circle, meeting the surface of the sphere in A, and join AD, AF; because AO is perpendicular to the plane DFE, the angles AOD, AOF are right angles; therefore AD = AF, hence A is the pole of the circle DFE.

COR. Since a perpendicular to the plane of the circle DFE through its centre must meet the sphere in two points; a great circle has two poles, A, B, which are the extremities of a diameter of the sphere perpendicular to the plane of the circle, and it can have no more.

THEOREM II. The arcs of a great circle between the poles and the circumference of another great circle are quadrants.

Let A and B be the poles of a great circle DFE, whose centre is O; let ADB be any other great circle that passes through A and B and meets the circle DFE in E: Because the poles of the circle DEF are at the extremities of AB, the diameter of the sphere that is perpendicular to its plane, the angles AOD, BOD are right angles, therefore AD, BD, the arcs of the circle ADB, are quadrants.

DEF. VI. A spherical angle is the angle on the surface of the sphere made by two great circles at their intersection: it is identical with the angle made by two straight lines in the planes of the circles which touch them at their intersection; and it is also the same as the angle made by the planes of the circles.

Let AEB, AFB, be two great circles that intersect each other at A and B (Fig. 2). From O the centre of the sphere, and A the intersection of the circles, draw OE and AP in the plane of the circle AEB, and OF, AQ in the plane of the circle AFB perpendicular to AB, the common section of the circles; the straight lines AP, AQ, will touch the circles at A, and form an angle PAQ, which is the spherical angle at A; and since PAQ is equal to EOF (Geometry, Part ii. 10, 1), the inclination of the planes of the circles, this last also expresses the spherical angle at A.

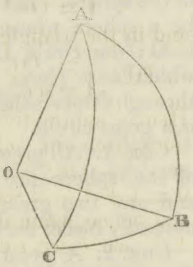
Cor. 1. The adjacent spherical angles which one great circle makes with another, are together equal to two right angles; and the vertical or opposite angles made by two great circles which cut one another are equal.

Cor. 2. The spherical angle made by two great circles is measured by an arc of a great circle whose pole is at their intersection.

Def. VII. A spherical triangle is a figure on the surface of the sphere comprehended by three arcs of great circles, each of which is less than a semicircle.

If planes be supposed to pass along the arcs AB, BC, AC, which are the sides of the triangle; these will pass through O, the centre of the sphere, and form at that point a solid angle O (Geometry, Def. vi. of Part ii).

Fig. 3.

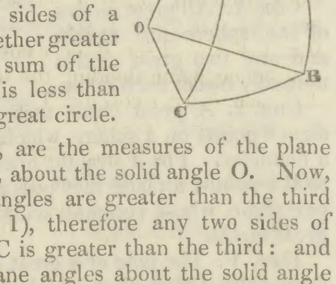


Theorem III. Any two sides of a spherical triangle are together greater than the third; and the sum of the arcs which are its sides is less than the circumference of a great circle.

The arcs AB, AC, BC, are the measures of the plane angles AOB, AOC, BOC, about the solid angle O. Now, any two of these plane angles are greater than the third (Geometry, Part ii. 16, 1), therefore any two sides of the spherical triangle ABC is greater than the third: and because the sum of the plane angles about the solid angle is less than four right angles (17); therefore the sum of the sides of the spherical triangle, which are their measures, must be less than the sum of four quadrants, that is, less than the circumference of a great circle.

Theorem IV. If about the angular points of a spherical triangle, as poles, there be described three great circles on the sphere; these by their intersections will form a triangle which is said to be *supplemental* to the former; and the two triangles are such, that the sides of the one are the supplements of the arcs which measure the angles of the other.

Fig. 4.



Let ABC be a spherical triangle; let EF be an arc of a great circle whose pole is A, and FD an arc of a great circle whose pole is B, and DE an arc of a great circle whose pole is C; these three arcs forming the triangle DEF. Let DB be an arc of a great circle passing through the points D, B, and DC an arc of a great circle passing through the points D, C. Because B is the pole of the arc DF, the arc BD is a quadrant (Th. II.), and because C is the pole of the arc DE, the arc CD is a quadrant. Since then the arcs BD, CD, are both quadrants, D is the pole of a great circle that passes through the points B, C; but only one great circle can pass through two points on the sphere not directly opposite, therefore D must be the pole of the arc BC. In the same way, it will appear that E is the pole of the arc AC, and F the pole of the arc AB. Produce the arcs AB, AC, if necessary, till they meet the arc EF in G and H; the point A being the pole of the arc GH, the angle A will be measured by GH. Now EH and FG being both quadrants, $EH + FG = 180°$; but $EH + FG = EF + GH$, therefore $EF + GH = 180°$, that is, EF, a side of the triangle DEF, is the supplement of GH, the measure of the angle A. In the very same way, it will appear that DF is the supplement of the angle B, and DE the supplement of the angle C; and because the triangle ABC may be formed from the triangle DEF exactly in the same way that DEF is constructed from ABC, namely, by describing great circles about the angles D, E, F, as poles, the triangles and their relations to each other may be interchanged. Hence it appears that BC, AC, AB, the sides of the triangle ABC, are the supplements of D, E, F, the angles of the triangle DEF.

Theorem V. The three angles of any spherical triangle are greater than two right angles, but less than six.

In the triangle ABC (fig. 4), the measures of the angles A, B, C, together with DE, EF, DF, the sides of the supplemental triangle DEF, make six right angles. (Th. IV.) Now the sum of the sides of the triangle DEF is less than four right angles (Th. III.), therefore the sum of the three angles A, B, C, is greater than two right angles; and because the three inward angles of any triangle, together with the adjacent exterior angles, are equal to six right angles, therefore the inward angles alone are less than six right angles.

4. We might proceed in this way, establishing the whole doctrine of spherical trigonometry by a series of synthetical demonstrations; such was the practice of the earlier writers on this subject. This however has now given way to a more convenient and elegant method of proceeding, which dispenses with complicated diagrams representing on a plane surface circles on a sphere. It deduces by the angular calculus the whole theory of spherical trigonometry (including also the theorems already here demonstrated) from a single proposition, in a manner probably first followed out by Bertrand of Geneva in his *Développement nouveau de la Partie Elémentaire des Mathématiques* (Geneva, 1778). Lagrange seems to have overlooked this work, for in his elegant memoir, entitled *Solutions de quelques Problèmes relatifs aux Triangles Sphériques, avec une Analyse complète de ces Triangles*, given in vol. ii. of *Journal de l'Ecole Polytechnique*, he has attributed the theorem to De Gua, who also gave it in the Memoirs of the Academy of Sciences for 1783.

5. Our article on the Arithmetic of Sines (Algebra, sect. 25) is an example of what may be done by the power of analysis alone in deducing an extensive theory from a few simple geometrical principles. Such is the way in which Lagrange and later writers treat of spherical trigonometry. We shall also follow the method of Delambre, who, in his *Astronomie Théorique et Pratique*, chap. x., instead of numerous rules deduced from geometrical constructions, for determining when angles or arcs are less or greater than quadrants, considers their sines and cosines as positive or negative quantities, according to the principles of analytic geometry, as explained at article 225 in Algebra. From what has been there explained, it appears that,

(1.) A sine is *positive* when the arc is less than 180°, but *negative* when the arc is between 180° and 360°.

Spherical Trigonometry.

(2.) If an arc be taken negatively, its sine is *negative* in e first half of the circle, but *positive* in the second.

(3.) The cosine of an arc $= 0$ is unity: it is 0 when the c $= 90°$; between *arc* $= 0$ and *arc* $= 90°$, the cosine is sitive, and between *arc* $= 90°$ and *arc* $= 270°$ the co- ne is *negative*, and between 270° and 360° it is *positive*. positive and a negative arc have the same cosine, so that a given cosine the arc may be taken either as *positive* or as gative.

(4.) Since $\tan. A = \frac{\sin. A}{\cos. A}$, the tangent is *positive* in the st quadrant of the circle, because the sine and cosine e both positive; it is *negative* in the second, because the ne is positive and the cosine negative; it is *positive* in the ird quadrant, because the sine and cosine are both nega- e; lastly, it is negative in the fourth quadrant, because e sine is negative and the cosine positive. The tangent $= 0$ when the arc is 0 or 180°, and *infinite* when the arc 90° or 270°.

(5.) When the arc is known, we can always give the tan- nt the proper sign. If the arc x is not known, and we have nply $\tan. x = a$, it cannot be known whether the arc be sitive or negative; if a be a positive number, the tangent longs alike to two arcs, x and $180° + x$. If a be ne- tive, $\tan. a$ belongs to an arc between 90° and 180°, or tween 270° and 360°. The problem therefore admits of o solutions.

But if $\tan. x = \frac{m}{n}$, and that the two terms of the fraction positive, then $x < 90°$. If m be positive and n nega- e, $x \geq 90°$; when m and n are both negative, $x \geq 180°$; tly, if m be negative and n positive, $x \geq 270°$.

(6.) The rule of the signs for cotangents is the same as the tangents, since $\tan. x = \frac{1}{\cot. x}$, or $\cot. x = \frac{1}{\tan. x}$.

(7.) The rule for the signs of secants is the same as t for cosines, seeing that $\sec. x = \frac{1}{\cos. x}$.

(8.) The rule for cosecants is the same as for sines, since $\text{cosec.}\, x = \frac{1}{\sin. x}$.

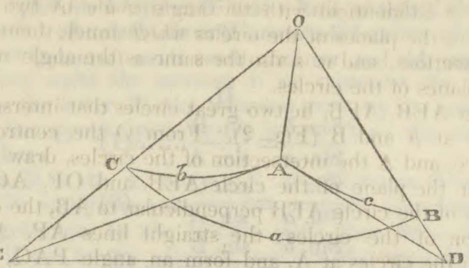
(9.) When an arc is known, the sign of its sine is known; t when x, an unknown arc, is to be found from $\sin. x =$ the sine belongs alike to x and $180° - x$, if a be posi- e; or to $180° + x$, and $360° - x$, if a be negative.

(10.) When an arc a is known, the sign of its cosine is own; but if we have $\cos. x = b$, we do not know whether be in the first or fourth quadrant if x is positive, or ether it be in the second or third when x is negative. e problem therefore has also, in this case, two solutions. e nature of the problem may however determine that ich the algebraic rule leaves ambiguous. Delambre, in Astronomy, says, "These rules are general, and easily nembered, and never mislead a calculator; while, on the ntrary, the rules with which most writers have compli- ed trigonometry, are so perplexing that there is hardly author that has not given false ones." The rule of the ns was long neglected by astronomers, on the known nciple that improvements come slowly into general use.

6. Let ABC be a spherical triangle, and let O be the ntre of the sphere; draw the radii OA, OB, OC. The id angle at O is contained by the three plane angles B, BOC, AOC, and the measures are the arcs AB, BC, , which are the sides of the triangle ABC.

At the point A in the plane AOB, draw AD touching the AB, and meeting the plane BOC in D; and in the ne AOC draw AE touching the arc AC, and meeting e plane BOC in E. The angle DAE contained by the ngents AD, AE, is the same as the spherical angle BAC ef. vi.). Join the points D, E by a straight line, which will be at once the base of the plane triangles DAE, DOE, the vertices of which are joined by the line AO, a radius of the sphere. We shall throughout make this line the *unit*, and express it by 1. Let us now denote the sides and angles of the spherical triangle ABC as follows.

Fig. 5.



The sides $BC = a$, $AC = b$, $AB = c$;
The angles $BAC = A$, $ABC = B$, $ACB = C$.

We have now

$$AE = \tan. b = \frac{\sin. b}{\cos. b}, \quad OE = \sec. b = \frac{1}{\cos. b},$$

$$AD = \tan. c = \frac{\sin. c}{\cos. c}, \quad OD = \sec. c = \frac{1}{\cos. c}.$$

By plane trigonometry (Th. VIII.), in the plane triangle ADE,

$$DE^2 \begin{cases} = AE^2 + AD^2 - 2\ AE \cdot AD \ \cos. A, \\ = \tan.^2 b + \tan.^2 c - 2 \tan. b \tan. c \cos. A; \end{cases}$$

and in the triangle ODE, we have also

$$DE^2 \begin{cases} = OE^2 + OD^2 - 2\, OE \cdot OD \ \cos. a, \\ = \sec.^2 b + \sec.^2 c - 2 \sec. b \sec. c \cos. a. \end{cases}$$

Hence, subtracting the sides of the first of these equations from the sides of the second, and considering that $\sec.^2 b - \tan.^2 b = 1$, $\sec.^2 c - \tan.^2 c = 1$, we have
$0 = 1 + 1 - 2 \sec. b \sec. c \cos. a + 2 \tan. b \tan. c \cos. A$;
and hence, again dividing the terms by 2, &c.

$$\sec. b \sec. c \cos. a = 1 + \tan. b \tan. c \cos. A;$$

that is, $\frac{\cos. a}{\cos. b \cos. c} = 1 + \frac{\sin. b \sin. c}{\cos. b \cos. c} \cos. A$;

and multiplying both sides by $\cos. b \cos. c$,

$$\cos. a = \cos. b \cos. c + \sin. b \sin. c \cos. A.$$

This is the formula given by Bertrand, and it comprehends in itself the whole principles of spherical trigonometry.

7. Since the same property must belong alike to the three sides, we may interchange the letters which represent them and the angles, and thus have

I.

$$\text{Cos. } a = \cos. b \cos. c + \sin. b \sin. c \cos. A \ldots (1)$$
$$\text{Cos. } b = \cos. a \cos. c + \sin. a \sin. c \cos. B \ldots (2)$$
$$\text{Cos. } c = \cos. a \cos. b + \sin. a \sin. b \cos. C \ldots (3)$$

8. To deduce other formulæ from these, we add and subtract the first and second, and thus get

$$\cos. b + \cos. a = \begin{cases} (\cos. b + \cos. a) \cos. c \\ + (\sin. a \cos. B + \sin. b \cos. A) \sin. c, \end{cases}$$

$$\cos. b - \cos. a = \begin{cases} -(\cos. b - \cos. a) \cos. c \\ + (\sin. a \cos. B - \sin. b \cos. A) \sin. c; \end{cases}$$

and from these again, by transposing the first term on the right-hand side,

$$(\cos. b + \cos. a)(1 - \cos. c) = \left\{ \begin{matrix} \sin. a \cos. B \\ + \sin. b \cos. A \end{matrix} \right\} \sin. c,$$

$$(\cos. b - \cos. a)(1 + \cos. c) = \left\{ \begin{matrix} \sin. a \cos. B \\ - \sin. b \cos. A \end{matrix} \right\} \sin. c;$$

and taking the products of the corresponding sides, and considering that $1 - \cos.^2 c = \sin.^2 c$, we have, after dividing by $\sin.^2 c$,

$$\cos.^2 b - \cos.^2 a = \sin.^2 a \cos.^2 B - \sin.^2 b \cos.^2 A.$$

Now, since $\cos.^2 b + \sin.^2 b = \cos.^2 a + \sin.^2 a$,
we have $\cos.^2 b - \cos.^2 a = \sin.^2 a - \sin.^2 b$;
therefore, $\sin.^2 a - \sin.^2 b = \sin.^2 a \cos.^2 B - \sin.^2 b \cos.^2 A$;

Spherical Trigonometry.

and $\sin.^2 a\,(1-\cos.^2 B)=\sin.^2 b\,(1-\cos.^2 A)$;

that is, $\sin.^2 a \sin.^2 B=\sin.^2 b \sin.^2 A$,

and $\sin. a \sin. B=\sin. b \sin. A$.

From this last, we form these three formulæ,

II.

$$\frac{\text{Sin. } b}{\text{Sin. } a}=\frac{\sin. B}{\sin. A}\ldots\ldots(1)$$

$$\frac{\text{Sin. } c}{\text{Sin. } a}=\frac{\sin. C}{\sin. A}\ldots\ldots(2)$$

$$\frac{\text{Sin. } b}{\text{Sin. } c}=\frac{\sin. B}{\sin. C}\ldots\ldots(3)$$

9. By No. 3 of formulæ (I.)

$$\cos. c=\cos. a \cos. b+\sin. a \sin. b \cos. C,$$

therefore $\cos. b \cos. c=\cos. a \cos.^2 b+\sin. a \cos. b \sin. b \cos. C$.

But by No. 1 of formulæ I.

$$\cos. b \cos\ c=\cos. a-\sin. b \sin. c \cos. A\,;$$

therefore $\cos. a-\sin. b \sin. c \cos. A=\cos. a \cos.^2 b+\sin. a \cos. b \sin. b \cos. C$;

and $\cos. a\,(1-\cos.^2 b)=\sin. b\,(\sin. c \cos. A+\sin. a \cos. b \cos. C)$.

In this expression put $\sin.^2 b$ for $1-\cos.^2 b$, and divide both sides by $\sin. b$; the result is

$$\cos. a \sin. b=\sin. c \cos. A+\sin. a \cos. b \cos. C\ldots.(m)$$

But by formula 2 of II. $\sin. c=\dfrac{\sin. a}{\sin. A}\sin. C$; therefore

$$\cos. a \sin. b=\sin. a \sin. C\,\frac{\cos. A}{\sin. A}+\sin. a \cos. b \cos. C.$$

Divide now by $\sin. a$, and put $\cot. a$ for $\dfrac{\cos. a}{\sin. a}$, and $\cot. A$ for $\dfrac{\cos. A}{\sin. A}$, and there is obtained

$$\cot. a \sin. b=\cot. A \sin. C+\cos. b \cos. C.$$

By changing b into c and C into B, we have also

$$\cot. a \sin. c=\cot. A \sin. B+\cos. c \cos. B.$$

By treating these two formulæ like those in articles 7 and 8, we obtain a class of six formulæ, viz.

III.

$$\text{Cot. } a \sin. b=\cot. A \sin. C+\cos. b \cos. C\ldots\ldots(1)$$
$$\text{Cot. } a \sin. c=\cot. A \sin. B+\cos. c \cos. B\ldots\ldots(2)$$

$$\text{Cot. } b \sin. a=\cot. B \sin. C+\cos. a \cos. C\ldots\ldots(3)$$
$$\text{Cot. } b \sin. c=\cot. B \sin. A+\cos. c \cos. A\ldots\ldots(4)$$

$$\text{Cot. } c \sin. a=\cot. C \sin. B+\cos. a \cos. B\ldots\ldots(5)$$
$$\text{Cot. } c \sin. b=\cot. C \sin. A+\cos. b \cos. A\ldots\ldots(6)$$

In these formulæ, the letters which represent the parts of the triangle are not so symmetrically arranged, as in the two former groups; and on that account they are less easily remembered. This inconvenience will be obviated by attention to the following remarks.

(1.) Both members of each formula begin with the product of a cotangent and a sine.

(2.) The first member is formed from any two of the three sides, and the first term of the second member contains an angle opposite to one of these, and the angle opposite to the side which is not in the first member.

(3.) The last term of the second member is formed by the two cosines of the same arcs of which the sines are already in the equation.

10. Resuming equation (m) in the preceding article, viz.

$$\cos. a \sin. b=\sin. a \cos. b \cos. C+\sin. c \cos. A,$$

change a into b and b into a, also A into B, and we have

$$\sin. a \cos. b=\sin. b \cos. a \cos. C+\sin. c \cos. B\,;$$

and multipling both sides by cos. C,

$$\sin. a \cos. b \cos. C=\sin. b \cos. a \cos.^2 C+\sin. c \cos. B \cos. C.$$

This value of $\sin. a \cos. b \cos. C$ being substituted in the former equation, it becomes

$$\cos. a \sin. b=\sin. b \cos. a \cos.^2 C+\sin. c\,(\cos. B \cos. C+\cos. A),$$

and by transposing the first term of the second side,

$$\cos. a \sin. b\,(1-\cos.^2 C)=\sin. c\,(\cos. B \cos. C+\cos. A),$$

that is, $\cos. a \sin. b \sin.^2 C=\sin. c\,(\cos. B \cos. C+\cos. A)$.

Now by (3) of formulæ II., $\sin. b \sin. C=\sin. c \sin. B$, therefore this last expression being substituted in the first side of the equation instead of its equal, and both sides being divided by $\sin. c$, we have

$$\cos. a \sin. B \sin. C=\cos. B \cos. C+\cos. A.$$

And by treating the expression just found, as we did those in articles 7, 8, 9, we have these formulæ:

IV.

$$\text{Cos. A}=-\cos. B \cos. C+\sin. B \sin. C \cos. a\ldots\ldots(1)$$
$$\text{Cos. B}=-\cos. A \cos. C+\sin. A \sin. C \cos. b\ldots\ldots(2)$$
$$\text{Cos. C}=-\cos. A \cos. B+\sin. A \sin. B \cos. c\ldots\ldots(3)$$

11. The sides of a spherical triangle being still denoted by a, b, c, and its angles by A, B, C, let A′, B′, C′, and a', b', c', be arcs or angles, such that

$$a+A'=180°,\ b+B'=180°,\ c+C'=180°;$$
$$A+a'=180°, B+b'=180°, C+c'=180°.$$

Then we have

$$\cos. a=-\cos. A',\ \cos. b=-\cos. B',\ \cos. c=-\cos. C',$$
$$\sin. a=\sin. A',\ \sin. b=\sin. B',\ \sin. c=\sin. C';$$
$$\cos. A=-\cos. a',\ \cos. B=-\cos. b',\ \cos. C=-\cos. c',$$
$$\sin. A=\sin. a',\ \sin. B=\sin. b',\ \sin. C=\sin. c.'$$

Let these values of the sines and cosines of a, b, c and A, B, C be substituted in formulæ I. and IV.; they then become

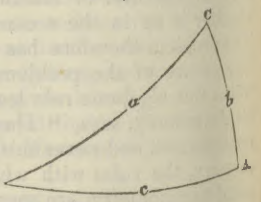
$$\cos. A'=-\cos. B' \cos. C'+\sin. B' \sin. C' \cos. a',$$
$$\cos. B'=-\cos. A' \cos. C'+\sin. A' \sin. C' \cos. b',$$
$$\cos. C'=-\cos. A' \cos. B'+\sin. A' \sin. B' \cos. c';$$

$$\cos. a'=\cos. b' \cos. c'+\sin. b' \sin. c' \cos. A',$$
$$\cos. b'=\cos. a' \cos. c'+\sin. a' \sin. c' \cos. B',$$
$$\cos. c'=\cos. a' \cos. b'+\sin. a' \sin. b' \cos. C'.$$

Hence, from I. and IV., if the arcs a', b', c' be taken as the sides of a spherical triangle, then the arcs A′, B′, C′ must necessarily be the measures of its angles; thus we have proved analytically our fourth theorem, which has been demonstrated in article 3, from considerations purely geometrical. This theorem, which has been known for two centuries past, may be expressed thus: *Any spherical triangle may be changed into another of which the sides and angles are respectively the supplements of the angles and sides of the first.* This is the supplement or polar triangle.

12. The four sets of formulæ which have been investigated in articles (6), (7), (8), (9), (10), are sufficient for resolving all cases of spherical triangles. When one of the angles is a right angle, they become more simple. We shall now adapt them to that case.

Fig. 6.



Right-Angled Spherical Triangles.

Let us suppose that A = 90°, then cos. A and cot. A are each = 0, and sin. A = 1.

From 1 and 2 of form. I. $\cos. a=\cos. b \cos. c$.

From 1 and 2 of II. $\begin{cases}\sin. B=\dfrac{\sin. b}{\sin. a},\\[2mm] \sin. C=\dfrac{\sin. c}{\sin. a}.\end{cases}$

From 1 and 2 of III. $\begin{cases}\cot. a \sin. b=\cos. b \cos. C,\\ \cot. a \sin\ c=\cos. c \cos. B.\end{cases}$

From 4 and 6 of III. $\begin{cases}\cot. b \sin. c=\cot. B,\\ \cot. c \sin. b=\cot. C.\end{cases}$

$$\text{From IV} \ldots\ldots\ldots\ldots\ldots \begin{cases} \cos. B \cos. C = \sin. B \sin. C \cos. a, \\ \cos. B = \sin. C \cos. b, \\ \cos. C = \sin. B \cos. c. \end{cases}$$

By considering that the cotangent of an arc is the reciprocal of the tangent, and that the tangent is equal to the ne divided by the cosine, we now obtain these ten formulæ for right-angled triangles, in which A is the right angle.

V.

$$\text{Cos. } a = \cos. b \cos. c. \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

$$\text{Sin. B} = \frac{\sin. b}{\sin. a}, \qquad \sin. C = \frac{\sin. c}{\sin. a} \ldots\ldots\ldots (2)\ (3)$$

$$\text{Cos. B} = \frac{\tan. c}{\tan. a}, \qquad \cos. C = \frac{\tan. b}{\tan. a} \ldots\ldots (4)\ (5)$$

$$\text{Tan. B} = \frac{\tan. b}{\sin. c}, \qquad \tan. C = \frac{\tan. c}{\sin. b} \ldots\ldots (6)\ (7)$$

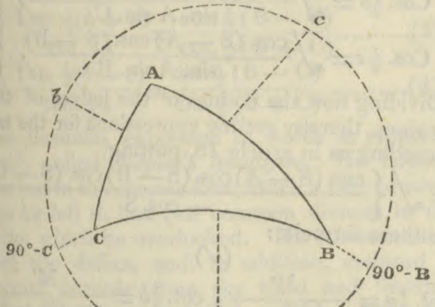
$$\text{Cos. } a = \cot. B \cot. C. \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (8)$$

$$\text{Cos. } b = \frac{\cos. B}{\sin. C}, \qquad \cos. c = \frac{\cos. C}{\sin. B} \ldots\ldots (9)\ (10)$$

13. These ten formulæ, which may however be exessed in words by six, are of continual use in astronomy. is therefore desirable that they should be comprehended the fewest number possible of practical rules, simple d easily remembered. Such were found by Napier, the ventor of logarithms, and are known by the name of *apier's Rules of the Circular Parts.* They are not new opositions, but are merely enunciations, which, by a partilar arrangement and classification of the parts of a trigle, include all the six proportions. They are perhaps e happiest example of artificial memory that is known.

In a right-angled spherical triangle ABC, setting aside e right angle A, there remain the sides AC = b and AB c about the right angle; the hypotenuse BC = a, and e two oblique angles B, C. The first two of these, viz. e sides b, c, and the complements of the remaining three, z. 90° — a, 90° — B, 90° — C, are called the five *circur* parts. They are called circular, because, when taken their order, they go round the triangle.

Fig. 7.



14. When one of the five circular parts is taken as the *iddle* part, the two next to it, one on each side, are called e *adjacent* parts; and the other two, each of which is serated from the middle by an adjacent part, are called the *posite* parts.

Thus, if 90° — a be the middle part, 90° — C and)° — B are the adjacent parts, and b and c the opposite rts; if 90° — B be the middle part, 90° — a and c are e adjacent parts, and 90° — C and b are the opposite rts; and if c be the middle part, 90° — B and b are the jacent parts, and 90° — a and 90° — C the opposite rts; and so on.

This arrangement being made, the rule of the circular rts is contained in the following proposition:

The rectangle under radius and the sine of the middle part is equal to the rectangle under the tangents of the adjacent parts; also to the rectangle under the cosines of the opposite parts.

It may assist the memory if we represent the middle part by the letter M, the adjacent parts by the letters A, a, and the opposite parts by the letters O, o; the rule will stand thus:

$$R \cdot \sin. M = \tan. A \cdot \tan. a; \quad R \cdot \sin. M = \cos. O \cdot \cos. 0.$$

15. To verify the rule, let 90° — a, the complement of the hypotenuse, be the middle part; then 90° — C, and 90° — B will be the adjacent, and b, c the opposite parts; and by the rule,

$$R \cdot \sin. (90° - a) \begin{cases} = \tan. (90° - B) \tan. (90° - C) \\ = \cos. b \cos. c; \end{cases}$$

$$\text{or } R \cdot \cos. a \begin{cases} = \cot. B \cot. C. & \text{This is form. (8)} \\ = \cos. b \cos. c & \text{This is form. (1)} \end{cases}$$

Let 90° — B, the complement of one of the oblique angles, be the middle part, then 90° — a and c are the adjacent parts, and 90° — C and b the opposite. The rule gives

$$R \cdot \cos. B \begin{cases} = \cot. a \tan. c \ldots\ldots\ldots\ldots \text{Form. (4, 5)} \\ = \sin. C \cos. b \ldots\ldots\ldots\ldots \text{Form. (9, 10)} \end{cases}$$

Let b, one of the sides about the right angle, be the middle part, then 90° — C and c will be the adjacent parts, and 90° — a and 90° — B the opposite parts. In this case, by the rule,

$$R \cdot \sin. b \begin{cases} = \cot. C \tan. c. \ldots\ldots\ldots \text{Form. (6, 7)} \\ = \sin. a \sin. B \ldots\ldots\ldots\ldots \text{Form. (2, 3)} \end{cases}$$

These are all the cases of right-angled triangles.

In applying the rule of the circular parts to resolve any case of right-angled triangles, consider which of the three quantities named (the two things given and the one required) must be made the middle term, in order that the other two may be equidistant from it, that is, may be both adjacent or both opposite; then the one or the other of the theorems which constitute the rule will give the value of the thing required.

Suppose, for example, that c a side about the right angle, and a the hypotenuse, are given to find the angle C. It appears that if c be made the middle part, then 90° — a and 90° — C are the opposite parts; and therefore that R · sin. c = sin. a sin. C, and sin. a : sin. c = R : sin. C.

16. Delambre has avowed that he found it easier to remember the six formulæ for right-angled triangles than to apply Napier's rules. In astronomy, the sun's longitude ($\odot$) is the hypotenuse of a right-angled triangle, of which the right ascension (Æ) and declination (D) are the sides about the right angle, the obliquity of the ecliptic (ω) is one of the oblique angles. Let the other oblique angle be denoted by A, then the six formulæ for right-angled spherical triangles adapted to astronomical calculation will stand thus:

$$\begin{aligned} \text{Sin. D} &= \sin. \omega \sin. \odot, \\ \tan. \text{Æ} &= \cos. \omega \tan. \odot, \\ \tan. D &= \tan. \omega \sin. \text{Æ}, \\ \cos. \odot &= \cos. \text{Æ} \cos. D, \\ \cos. \odot &= \cot. \omega \cot. A, \\ \cos. A &= \sin. \omega \cos. \text{Æ}. \end{aligned}$$

The practical astronomer, who has continual occasion to use the first four of these formulæ, will find no difficulty in retaining them in his memory. But Napier's rules will probably be most easily remembered by students of that science.

17. The general formulæ, I., II., III., IV., serve for all spherical triangles; but they admit of transformations, which make them more convenient for logarithmic calculation.

Resuming the formulæ, (I.) we put the first under these two forms.

Spherical Trigonometry.

$$\text{Cos.}\,a=(\cos.\,b\cos.\,c-\sin.\,b\sin.\,c)+\sin.\,b\sin.\,c(1+\cos.\text{A}),$$
$$\text{Cos.}\,a=(\cos.\,b\cos.\,c+\sin.\,b\sin.\,c)-\sin.\,b\sin.\,c(1-\cos.\,\text{A}).$$

Now, by the calculus of sines (ALGEBRA, articles 239 and 248),

$$\text{Cos.}\,b\cos.\,c-\sin.\,b\sin.\,c=\cos.\,(b+c),$$
$$\text{Cos.}\,b\cos.\,c+\sin.\,b\sin.\,c=\cos.\,(b-c),$$
$$1+\cos.\,\text{A}=2\cos.^2\tfrac{1}{2}\text{A},\quad 1-\cos.\,\text{A}=2\sin.^2\tfrac{1}{2}\text{A}.$$

Hence, by substituting, we get

$$\text{Cos.}\,a=\cos.\,(b+c)+2\sin.\,b\sin.\,c\cos.^2\tfrac{1}{2}\text{A},$$
$$\text{Cos.}\,a=\cos.\,(b-c)-2\sin.\,b\sin.\,c\sin.^2\tfrac{1}{2}\text{A};$$

and transposing, and observing that by the calculus of sines (ALGEBRA, art. 240),

$$\text{Cos.}\,a-\cos.\,(b+c)=2\sin.\tfrac{1}{2}(a+b+c)\sin.\tfrac{1}{2}(b+c-a),$$
$$\text{Cos.}\,(b-c)-\cos.\,a=2\sin.\tfrac{1}{2}(a+c-b)\sin.\tfrac{1}{2}(a+b-c),$$

we have

$$\text{Sin.}\,b\sin.\,c\cos.^2\tfrac{1}{2}\text{A}=\sin.\tfrac{1}{2}(a+b+c)\sin.\tfrac{1}{2}(b+c-a),$$
$$\text{Sin.}\,b\sin.\,c\sin.^2\tfrac{1}{2}\text{A}=\sin.\tfrac{1}{2}(a+c-b)\sin.\tfrac{1}{2}(a+b-c).$$

To abridge, let us put $\frac{1}{2}(a+b+c)=s$;

$$\text{then }\tfrac{1}{2}(b+c-a)=s-a,$$
$$\tfrac{1}{2}(a+c-b)=s-b,$$
$$\tfrac{1}{2}(a+b-c)=s-c.$$

We have now $\cos.^2\frac{1}{2}\text{A}=\dfrac{\sin.\,s\sin.\,(s-a)}{\sin.\,b\sin.\,c}$,

$$\sin.^2\tfrac{1}{2}\text{A}=\frac{\sin.\,(s-b)\sin.\,(s-c)}{\sin.\,b\sin.\,c}.$$

There are expressions exactly like these for the squares of the cosines and sines of the halves of the angles B, C; and from the whole we obtain

$$\left.\begin{aligned}\text{Cos.}\tfrac{1}{2}\text{A}&=\sqrt{\frac{\sin.\,s\sin.\,(s-a)}{\sin.\,b\sin.\,c}},\\ \text{Cos.}\tfrac{1}{2}\text{B}&=\sqrt{\frac{\sin.\,s\sin.\,(s-b)}{\sin.\,a\sin.\,c}},\\ \text{Cos.}\tfrac{1}{2}\text{C}&=\sqrt{\frac{\sin.\,s\sin.\,(s-c)}{\sin.\,a\sin.\,b}}.\end{aligned}\right\}\ldots\ldots(\alpha)$$

$$\left.\begin{aligned}\text{Sin.}\tfrac{1}{2}\text{A}&=\sqrt{\frac{\sin.\,(s-b)\sin.\,(s-c)}{\sin.\,b\sin.\,c}},\\ \text{Sin.}\tfrac{1}{2}\text{B}&=\sqrt{\frac{\sin.\,(s-a)\sin.\,(s-c)}{\sin.\,a\sin.\,c}},\\ \text{Sin.}\tfrac{1}{2}\text{C}&=\sqrt{\frac{\sin.\,(s-a)\sin.\,(s-b)}{\sin.\,a\sin.\,b}}.\end{aligned}\right\}\ldots(\beta)$$

18. Because $\tan.^2\frac{1}{2}\text{A}=\dfrac{\sin.^2\frac{1}{2}\text{A}}{\cos.^2\frac{1}{2}\text{A}}$, therefore

$$\tan.^2\tfrac{1}{2}\text{A}=\frac{\sin.\,(s-b)\sin.\,(s-c)}{\sin.\,s\sin.\,(s-a)}$$
$$=\frac{1}{\sin.^2(s-a)}\cdot\frac{\sin.\,(s-a)\sin.\,(s-b)\sin.\,(s-c)}{\sin.\,s}.$$

Put M to denote $\sqrt{\left\{\dfrac{\sin.(s-a)\sin.\,(s-b)\sin.(s-c)}{\sin.\,s}\right\}}$, and it is observable that in this expression the sides a, b, c enter exactly alike. We have now $\tan.\frac{1}{2}\text{A}=\dfrac{\text{M}}{s-a}$. By putting B and b, also C and c, successively, instead of A and a, we find like expressions for the tangents of $\frac{1}{2}$B and $\frac{1}{2}$C. Thus we have these three formulæ:

$$\left.\begin{aligned}\tan.\tfrac{1}{2}\text{A}=\frac{\text{M}}{\sin.(s-a)},\ \tan.\tfrac{1}{2}\text{B}&=\frac{\text{M}}{\sin.\,(s-b)},\\ \tan.\tfrac{1}{2}\text{C}&=\frac{\text{M}}{\sin.\,(s-c)}.\end{aligned}\right\}\ldots(\gamma)$$

The formulæ in this and the preceding article are exactly like those found for the angles of plane triangles. Those for the tangents of half the angles (which we believe to be given in this form for the first time) seem to be most convenient for use in all cases. In using the others, if half the angle sought be nearly a quadrant, its cosine ought to be sought rather than its sine; and the reverse, if the angle be small.

19. We may treat our fourth group of formulæ, of which the first is

$$\text{Cos.}\,\text{A}=-\cos.\,\text{B}\cos.\,\text{C}+\sin.\,\text{B}\sin.\,\text{C}\cos.\,a,$$

in all respects as we have the first, putting it under these forms:

$$\text{Cos.}\,\text{A}=-(\cos.\,\text{B}\cos.\,\text{C}-\sin.\,\text{B}\sin.\,\text{C})$$
$$-\sin.\,\text{B}\sin.\,\text{C}\,(1-\cos.\,a),$$
$$\text{Cos.}\,\text{A}=-(\cos.\,\text{B}\cos.\,\text{C}+\sin.\,\text{B}\sin.\,\text{C})$$
$$+\sin.\,\text{B}\sin.\,\text{C}\,(1+\cos.\,a);$$

from which we have, by the calculus of sines (ALGEBRA, art. 239), &c.

$$\text{Cos.}\,\text{A}+\cos.\,(\text{B}+\text{C})=-\sin.\,\text{B}\sin.\,\text{C}\,(1-\cos.\,a),$$
$$\text{Cos.}\,\text{A}+\cos.\,(\text{B}-\text{C})=\sin.\,\text{B}\sin.\,\text{C}\,(1+\cos.\,a).$$

Now

$$\text{Cos.A}+\cos.(\text{B}+\text{C})=2\cos.\tfrac{1}{2}(\text{A}+\text{B}+\text{C})\cos.\tfrac{1}{2}(\text{B}+\text{C}-\text{A}),$$
$$\text{Cos.A}+\cos.(\text{B}-\text{C})=2\cos.\tfrac{1}{2}(\text{A}+\text{C}-\text{B})\cos.(\text{A}+\text{B}-\text{C}),$$
$$1-\cos.\,a=2\sin.^2\tfrac{1}{2}a,\qquad 1+\cos.\,a=2\cos.^2\tfrac{1}{2}a.$$

Therefore, putting

$$\text{S}=\tfrac{1}{2}(\text{A}+\text{B}+\text{C}),$$
$$\text{so that S}-\text{A}=\tfrac{1}{2}(\text{B}+\text{C}-\text{A}),$$
$$\text{S}-\text{B}=\tfrac{1}{2}(\text{A}+\text{C}-\text{B}),$$
$$\text{S}-\text{C}=\tfrac{1}{2}(\text{A}+\text{B}-\text{C}),$$

we have

$$\text{Sin.}\,\text{B}\sin.\,\text{C}\sin.^2\tfrac{1}{2}a=-\cos.\,\text{S}\cos.\,(\text{S}-\text{A}),$$
$$\text{Sin.}\,\text{B}\sin.\,\text{C}\cos.^2\tfrac{1}{2}a=\cos.\,(\text{S}-\text{B})\cos.\,(\text{S}-\text{C}).$$

There are like expressions which involve the squares of the sines and cosines of $\frac{1}{2}b$ and $\frac{1}{2}c$, from all which we deduce

$$\left.\begin{aligned}\text{Sin.}\,\tfrac{1}{2}a&=\sqrt{\frac{-\cos.\,\text{S}\cos.\,(\text{S}-\text{A})}{\sin.\,\text{B}\sin.\,\text{C}}},\\ \text{Sin.}\,\tfrac{1}{2}b&=\sqrt{\frac{-\cos.\,\text{S}\cos.\,(\text{S}-\text{B})}{\sin.\,\text{A}\sin.\,\text{C}}},\\ \text{Sin.}\,\tfrac{1}{2}c&=\sqrt{\frac{-\cos.\,\text{S}\cos.\,(\text{S}-\text{C})}{\sin.\,\text{A}\sin.\,\text{B}}};\end{aligned}\right\}\ldots(\alpha')$$

$$\left.\begin{aligned}\text{Cos.}\,\tfrac{1}{2}a&=\sqrt{\frac{\cos.\,(\text{S}-\text{B})\cos.\,(\text{S}-\text{C})}{\sin.\,\text{B}\sin.\,\text{C}}},\\ \text{Cos.}\,\tfrac{1}{2}b&=\sqrt{\frac{\cos.\,(\text{S}-\text{A})\cos.\,(\text{S}-\text{C})}{\sin.\,\text{A}\sin.\,\text{C}}},\\ \text{Cos.}\,\tfrac{1}{2}c&=\sqrt{\frac{\cos.\,(\text{S}-\text{A})\cos.\,(\text{S}-\text{B})}{\sin.\,\text{A}\sin.\,\text{B}}}.\end{aligned}\right\}(\beta')$$

20. Dividing now the cosines of the halves of the sides by their sines, thereby getting expressions for the tangents, and proceeding as in article 18, putting

$$\text{M}'=\sqrt{\left\{\frac{\cos.\,(\text{S}-\text{A})\cos.\,(\text{S}-\text{B})\cos.\,(\text{S}-\text{C})}{-\cos.\,\text{S}}\right\}},$$

we have these formulæ:

$$(\gamma')$$
$$\text{Cot.}\,\tfrac{1}{2}a=\frac{\text{M}'}{\cos.\,(\text{S}-\text{A})},\ \cot.\,\tfrac{1}{2}b=\frac{\text{M}'}{\cos.\,(\text{S}-\text{B})},$$
$$\cot.\,\tfrac{1}{2}c=\frac{\text{M}'}{\cos.\,(\text{S}-\text{C})}.$$

The sum of the three angles of a spherical triangle always exceeds two right angles; therefore S, half their sum, exceeds a quadrant; and hence cos. S will be a negative quantity, and — cos. S will be positive, and its square root a real quantity.

In astronomical calculations, it very seldom happens that the angles are wanted, from the three sides being given.

21. Recurring to the formulæ (α), (β) of article 17, we deduce from them the following equations.

$$\frac{\text{Sin.}\,\frac{1}{2}\text{B}\cos.\,\frac{1}{2}\text{C}}{\cos.\,\frac{1}{2}\text{A}}=\frac{\sin.\,(s-c)}{\sin.\,a}=\frac{\sin.\,\frac{1}{2}(a+b-c)}{\sin.\,a},$$
$$\frac{\text{Sin.}\,\frac{1}{2}\text{C}\cos.\,\frac{1}{2}\text{B}}{\cos.\,\frac{1}{2}\text{A}}=\frac{\sin.\,(s-b)}{\sin.\,a}=\frac{\sin.\,\frac{1}{2}(a+c-b)}{\sin.\,a},$$

$$\frac{\text{Cos.}\tfrac{1}{2}\text{B}\cos.\tfrac{1}{2}\text{C}}{\sin.\tfrac{1}{2}\text{A}}=\frac{\sin.s}{\sin.a}=\frac{\sin.\tfrac{1}{2}(a+b+c)}{\sin.a},$$

$$\frac{\text{Sin.}\tfrac{1}{2}\text{B}\sin.\tfrac{1}{2}\text{C}}{\sin.\tfrac{1}{2}\text{A}}=\frac{\sin.(s-a)}{\sin.a}=\frac{\sin.\tfrac{1}{2}(b+c-a)}{\sin.a}.$$

By adding and subtracting the sides of these equations, and observing that

$$\text{Sin.}\tfrac{1}{2}\text{B}\cos.\tfrac{1}{2}\text{C}\pm\sin.\tfrac{1}{2}\text{C}\cos.\tfrac{1}{2}\text{B}=\sin.\tfrac{1}{2}(\text{B}\pm\text{C}),$$
$$\text{Cos.}\tfrac{1}{2}\text{B}\cos.\tfrac{1}{2}\text{C}\mp\sin.\tfrac{1}{2}\text{B}\sin.\tfrac{1}{2}\text{C}=\cos.\tfrac{1}{2}(\text{B}\pm\text{C}),$$
$$\text{Sin.}\tfrac{1}{2}(a+b-c)+\sin.\tfrac{1}{2}(a+c-b)=2\sin.\tfrac{1}{2}a\cos.\tfrac{1}{2}(b-c),$$
$$\text{Sin.}\tfrac{1}{2}(a+b-c)-\sin.\tfrac{1}{2}(a+c-b)=2\cos.\tfrac{1}{2}a\sin.\tfrac{1}{2}(b-c),$$
$$\text{Sin.}\tfrac{1}{2}(a+b+c)-\sin.\tfrac{1}{2}(b+c-a)=2\sin.\tfrac{1}{2}a\cos.\tfrac{1}{2}(b+c),$$
$$\text{Sin.}\tfrac{1}{2}(b+c+a)+\sin.\tfrac{1}{2}(b+c-a)=2\cos.\tfrac{1}{2}a\sin.\tfrac{1}{2}(b+c),$$
$$\text{Sin.}a=2\sin.\tfrac{1}{2}a\cos.\tfrac{1}{2}a,$$

(as has been proved in ALGEBRA, articles 240 and 247), we obtain the following results:

$$(\delta)$$

$$\frac{\text{Sin.}\tfrac{1}{2}(\text{B}+\text{C})}{\cos.\tfrac{1}{2}\text{A}}=\frac{\cos.\tfrac{1}{2}(b-c)}{\cos.\tfrac{1}{2}a}\;\ldots\ldots\ldots(1)$$

$$\frac{\text{Sin.}\tfrac{1}{2}(\text{B}-\text{C})}{\cos.\tfrac{1}{2}\text{A}}=\frac{\sin.\tfrac{1}{2}(b-c)}{\sin.\tfrac{1}{2}a}\;\ldots\ldots\ldots(2)$$

$$\frac{\text{Cos.}\tfrac{1}{2}(\text{B}+\text{C})}{\sin.\tfrac{1}{2}\text{A}}=\frac{\cos.\tfrac{1}{2}(b+c)}{\cos.\tfrac{1}{2}a}\;\ldots\ldots\ldots(3)$$

$$\frac{\text{Cos.}\tfrac{1}{2}(\text{B}-\text{C})}{\sin.\tfrac{1}{2}\text{A}}=\frac{\sin.\tfrac{1}{2}(b+c)}{\sin.\tfrac{1}{2}a}\;\ldots\ldots\ldots(4)$$

These formulæ were first given by Gauss, in his work *Theoria Motus Corporum Cælestium.*

22. Let us now divide the sides of formula (1) by those of formula (3), also the sides of (2) by the sides of (4), and the sides of (4) by the sides of (3), and, lastly, the sides of (2) by the sides of (1); and put *tan.* in the results instead of $\frac{sin.}{cos.}$, also *cot.* instead of $\frac{cos.}{sin.}$; we then have

$$(\varepsilon)$$

$$\frac{\text{Tan.}\tfrac{1}{2}(\text{B}+\text{C})}{\cot.\tfrac{1}{2}\text{A}}=\frac{\cos.\tfrac{1}{2}(b-c)}{\cos.\tfrac{1}{2}(b+c)}\;\ldots\ldots\ldots(1)$$

$$\frac{\text{Tan.}\tfrac{1}{2}(\text{B}-\text{C})}{\cot.\tfrac{1}{2}\text{A}}=\frac{\sin.\tfrac{1}{2}(b-c)}{\sin.\tfrac{1}{2}(b+c)}\;\ldots\ldots\ldots(2)$$

$$\frac{\text{Tan.}\tfrac{1}{2}(b+c)}{\tan.\tfrac{1}{2}a}=\frac{\cos.\tfrac{1}{2}(\text{B}-\text{C})}{\cos.\tfrac{1}{2}(\text{B}+\text{C})}\;\ldots\ldots\ldots(3)$$

$$\frac{\text{Tan.}\tfrac{1}{2}(b-c)}{\tan.\tfrac{1}{2}a}=\frac{\sin.\tfrac{1}{2}(\text{B}-\text{C})}{\sin.\tfrac{1}{2}(\text{B}+\text{C})}\;\ldots\ldots\ldots(4)$$

These formulæ, expressed in words as proportions, are commonly called *Napier's analogies.* He however only gave the last in the concise form which it here presents. The third, as he left it, had two common divisors in the terms of a ratio, which he overlooked. His commentator Briggs removed the defect, and, in addition, deduced the first and second formulæ from the third and fourth by the theorem here demonstrated in art. 11. Thus he is entitled to share with Napier in the honour of having discovered these very elegant properties of spherical triangles.

From the first and second of these formulæ, there is found, by division, this other formula:

$$(\zeta)$$

$$\frac{\text{Tan.}\tfrac{1}{2}(\text{B}+\text{C})}{\text{Tan.}\tfrac{1}{2}(\text{B}-\text{C})}=\frac{\tan.\tfrac{1}{2}(b+c)}{\tan.\tfrac{1}{2}(b-c)}.$$

This formula is also due to Napier.

23. There are some properties of spherical triangles which may be more concisely proved by the formulæ than by geometrical reasoning. Such are those which follow.

I. In a spherical triangle, the greater angle is opposite to the greater side, and conversely.

Let a, b, c be the sides of a spherical triangle, and B, C the angles opposite to the sides b, c. It appears from formula (2) of δ, article 21, that

$$\frac{\text{Sin.}\tfrac{1}{2}(\text{B}-\text{C})}{\text{Sin.}\tfrac{1}{2}(b-c)}=\frac{\cos.\tfrac{1}{2}\text{A}}{\cos.\tfrac{1}{2}a}.$$

The second member of this equation is always a positive quantity, therefore the first must also be positive. This can only be true on the hypothesis that when b is greater than c, then B is also greater than C. The truth of the converse follows from the same principle.

II. The angles at the base of an isosceles triangle are equal, and conversely.

For we have

$$\text{Cos.}\tfrac{1}{2}a\sin.\tfrac{1}{2}(\text{B}-\text{C})=\cos.\tfrac{1}{2}\text{A}\sin.\tfrac{1}{2}(b-c).$$

When $b=c$, the second side of the equation becomes $=0$, therefore the first side must also be $=0$. This requires that $\text{B}=\text{C}$. The converse follows from the same formula.

III. Any two sides of a spherical triangle are together greater than the third.

It appears from article 17, that

$$\text{Sin.}\tfrac{1}{2}(b+c-a)=\frac{\sin.b\sin.c\cos.^2\tfrac{1}{2}\text{A}}{\sin.\tfrac{1}{2}(a+b+c)}.$$

The second side of this equation is always a positive quantity, therefore the first must also be positive. This requires that $b+c$ be in every case greater than a. This proposition has been otherwise proved geometrically, Theorem III.

IV. We have found (article 21) that

$$\text{Cos.}\tfrac{1}{2}(b+c)\sin.\tfrac{1}{2}\text{A}=\cos.\tfrac{1}{2}(\text{B}+\text{C})\cos.\tfrac{1}{2}a.$$

Now $\sin.\tfrac{1}{2}\text{A}$ and $\cos.\tfrac{1}{2}a$ are always positive, because each arc is less than a quadrant. Therefore $\cos.\tfrac{1}{2}(b+c)$ and $\cos.\tfrac{1}{2}(\text{B}+\text{C})$ have always the same sign; and hence $\tfrac{1}{2}(b+c)$ and $\tfrac{1}{2}(\text{B}+\text{C})$ are of the same affection, and $\text{B}+\text{C}$, $b+c$, either both less than a semicircle, or both equal to it, or both greater.

V. The hypotenuse a of a right-angled spherical triangle is less or greater than 90°, according as the sides b, c, about the right angle A, are of the same affection, or of different affection; that is, in the former case, both less or both greater than 90°; and in the latter, one less and the other greater than 90°.

This follows immediately from the formula $\cos.a=\cos.b\cos.c$ (art. 12); for if b and c be both less than 90° or both greater, they have like signs, and their product has the sign $+$, which indicates that a is less than 90°. If one of the two b, c be less and the other greater than 90°, they will have different signs, and the sign of their product will be $-$, and a must be greater than 90°.

VI. The same rule applies to each of the sides b, c; for b will be less than 90° if a and c be of the same affection, but greater than 90° if a and c are of different affection.

VII. The formula $\cos.a=\cot.\text{B}\cot.\text{C}$ shows that the hypotenuse a will be less than 90° when B and C are of the same affection, but greater than 90° if they be of different affection.

VIII. Also, that either of the angles B, C, will be less than 90° if a and the other angle be of the same affection, but greater than 90° if they be of different affection.

IX. The formula $\cos.\text{B}=\cos.b\sin.c$ shows that the angle B and the opposite side b are always of the same affection.

X. The formula $\tan.c=\tan.a\cot.\text{B}$ shows that the hypotenuse a and either side c are of the same affection if the angle they contain be acute, but of different affection if the angle be obtuse.

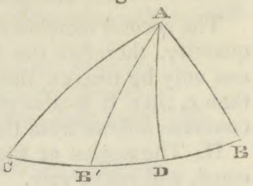
XI. Lastly, the formula $\tan.b=\sin.c\tan.\text{B}$ proves that the side and the opposite angle are always of the same affection.

XII. In any spherical triangle ABC, draw AD an arc of a great circle perpendicular to the base BC, thus forming two right-angled triangles ADC, ADB, which have

Spherical Trigonometry.

a common side AD. We have (art. 13) tan. AD = tan. C sin. CD = tan. B sin. BD; hence the angles ACD, ABD, are either both acute or both obtuse. If therefore ACB and ABC be of the same affection, the perpendicular falls within the triangle ABC; but if the angles ACB′ and AB′C are of contrary affection, the perpendicular falls without the triangle AB′C.

Fig. 8.



Solution of Right-Angled Triangles.

A spherical triangle may have one right angle, or it may have two, or three. If it have two right angles, the sides opposite to these will be quadrants, and the third the measure of the remaining angle. If it have three right angles, it will be equilateral, and its sides quadrants. We shall set aside these cases, and consider only that in which one of the angles is a right angle, and the other two oblique, which may be either acute or obtuse. The side opposite to the right angle is named the hypotenuse.

The solutions are to be derived from the formulæ in art. 12; and as in the investigations, to abridge, the radius was supposed to be the unit, we shall in the rules express it as in the formulæ of plane trigonometry by the letter R.

CASE I. Given the hypotenuse a and b, one of the sides about the right angle, to find the other side c, and the oblique angles B, C. These are to be found from formulæ (1), (2, 3), (4, 5).

SOLUTION.

$$\text{Cos. } c = \frac{\text{cos. } a}{\text{cos. } b}\text{R},\quad \text{sin. B} = \frac{\text{sin. } b}{\text{sin. } a}\text{R},\quad \text{cos. C} = \frac{\text{tan. } b}{\text{tan. } a}\text{R}.$$

If a and b be of the same affection, then c must be less than a quadrant, and also the measure of the angle C. But if a and b be of different affection, then the side c and the angle c must be both greater than quadrants. The angle B and the side b will be of the same affection.

CASE II. Given the sides b and c about the right angle, to find the hypotenuse a, and the angles B, C. Here the formulæ to be used are (1), (6, 7).

SOLUTION.

$$\text{Cos. } a = \frac{\text{cos. } b \text{ cos. } c}{\text{R}},\quad \text{tan. B} = \frac{\text{tan. } b}{\text{sin. } c}\text{R},\quad \text{tan. C} = \frac{\text{tan. } c}{\text{sin. } b}\text{R}.$$

In all the cases it must be considered whether the arcs found be less or greater than quadrants, by the algebraic signs + or —, which belong to the given arcs and angles as expressed in article 5.

CASE III. Given the hypotenuse a, and an oblique angle B, to find the sides b, c, and the other oblique angle C. The formulæ to be employed are (2, 3), (4, 5).

SOLUTION.

$$\text{Sin. } b = \frac{\text{sin. } a \text{ sin. B}}{\text{R}},\quad \text{tan. } c = \frac{\text{tan. } a \text{ cos. B}}{\text{R}},$$

$$\text{cos. C} = \frac{\text{tan. } b}{\text{tan. } a}\text{R}.$$

CASE IV. Given a side b and the opposite angle B, to find the hypotenuse a, the side c, and the angle C. This is resolved by (2, 3), (6, 7), (9, 10).

SOLUTION.

$$\text{Sin. } a = \frac{\text{sin. } b}{\text{sin. B}}\text{R},\quad \text{sin. } c = \frac{\text{tan. } b}{\text{tan. B}}\text{R},\quad \text{sin. C} = \frac{\text{cos. B}}{\text{cos. } b}\text{R}.$$

In this case each of the things required has two values, because an arc and its supplement have the same sine. Hence two distinct triangles may be found from the same data; this is called the *ambiguous* case of right-angled spherical triangles.

CASE V. Given a side b with the adjacent angle C, to find the hypotenuse a, the side c, and the angle B. These are to be found by (4, 5), (6, 7), (9, 10).

SOLUTION.

$$\text{Tan. } a = \frac{\text{tan. } b}{\text{cos. C}}\text{R},\quad \text{tan. } c = \frac{\text{sin. } b \text{ tan. C}}{\text{R}},$$

$$\text{cos. B} = \frac{\text{cos. } b \text{ sin. C}}{\text{R}}.$$

CASE VI. Given the two oblique angles B, C, to find the hypotenuse a, and the sides b, c. These are found by (8), (9, 10).

SOLUTION.

$$\text{Cos. } a = \frac{\text{cot. B cot. C}}{\text{R}},\quad \text{cos. } b = \frac{\text{cos. B}}{\text{sin. C}}\text{R},\quad \text{cos. } c = \frac{\text{cos. C}}{\text{sin. B}}\text{R}.$$

In addition to what has been said in regard to the arcs or angles sought being less or greater than quadrants, it may be useful to remember, that when the thing to be found by the formulæ is either a tangent or a cosine, and when of the tangents or cosines employed in its computation, one only is an obtuse angle, the angle required is also obtuse. In what follows we shall consider R = 1.

Oblique-Angled Spherical Triangles.

24. Before entering on these, we shall resolve this problem.

PROBLEM. Let M, N, P be given quantities, and x an unknown arc or angle; it is proposed to find x from this equation:

$$\text{M cos. } x + \text{N sin. } x = \text{P}.$$

Let us assume M = v cos. φ, N = v sin. φ; where v denotes a number, and φ an angle, both to be determined. Our equation may now be expressed thus.

$$v\,(\text{cos. } \varphi \text{ cos. } x + \text{sin. } \varphi \text{ sin. } x) = \text{P};$$

$$\text{hence } v \text{ cos. } (x - \varphi) = \text{P, and cos. } (x - \varphi) = \frac{\text{P}}{v}.$$

$$\text{Now tan. } \varphi = \frac{v \text{ sin. } \varphi}{v \text{ cos. } \varphi} = \frac{\text{N}}{\text{M}} \text{.........} (1)$$

$$\text{and } v = \frac{\text{M}}{\text{cos. } \varphi} = \frac{\text{N}}{\text{sin. } \varphi}.$$

$$\text{Therefore cos. } (x - \varphi) = \frac{\text{P}}{\text{M}} \text{ cos. } \varphi = \frac{\text{P}}{\text{N}} \text{ sin. } \varphi \text{....} (2)$$

The angle φ is determined by the first equation, and the angle $(x - \varphi)$ by the second; therefore $x = (x - \varphi) + \varphi$ is found.

If we assume M = v sin. φ, and N = v cos. φ, we have

$$v\,(\text{sin. } \varphi \text{ cos. } x + \text{cos. } \varphi \text{ sin. } x) = \text{P},$$

$$\text{and } v \text{ sin. } (x + \varphi) = \text{P};$$

$$\text{then cot. } \varphi = \frac{\text{N}}{\text{M}} \text{.......................} (1)$$

$$\text{and sin. } (x + \varphi) = \frac{\text{P}}{\text{M}} \text{ sin. } \varphi = \frac{\text{P}}{\text{N}} \text{ cos. } \varphi \text{.......} (2)$$

Thus φ and $x = (x + \varphi) - \varphi$ are both determined.

The assumptions tan. φ or cot. φ are evidently always possible, since an arc φ may be found whose tangent or cotangent shall have any real value whatever.

Fig. 9.

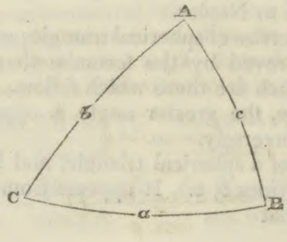


Fig. 10.

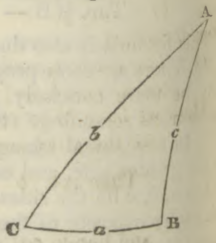


25. There are six cases of oblique-angled triangles, hich may be resolved by the formulæ which have been investigated; but in some cases they will be modified so to adapt them to logarithmic calculation.

Case I. Given the three sides a, b, c, to find the angles A, B, C.

Solution. Find $s = \frac{1}{2}(a + b + c)$,

and $M = \surd \left\{ \frac{\sin.(s - a) \sin.(s - b) \sin.(s - c)}{\sin. s} \right\}$; then

$$\text{Tan.} \tfrac{1}{2}A = \frac{M}{\sin.(s - a)},\ \tan. \tfrac{1}{2}B = \frac{M}{\sin.(s - b)},$$

$$\text{Tan.} \tfrac{1}{2}C = \frac{M}{\sin.(s - c)}.$$

This solution has been found in article 18.

Case II. Given two sides a and b, and the angle A opposite.

(1.) The angle B may be found from formula II. thus:

$$\text{Sin.} B = \frac{\sin. A \sin. b}{\sin. a}.$$

The affection of B is ambiguous, unless it can be determined by the rule A + B is greater or less than 180°, according as $a + b$ is greater or less than 180° (art. 23).

(2.) The side c is to be found from this equation:

$$[\cos. b] \cos. c + [\sin. b \cos. A] \sin. c = \cos. a.$$

Comparing this with the equation of art. 24, viz. $M \cos. x + N \sin. x = P$, we have

$$M = \cos. b, \quad N = \sin. b \cos. A, \quad P = \cos. a;$$

and following the analysis by which the angle x has been there determined, we find that if

$$\text{Tan.} \varphi = \tan. b \cos. A,$$

$$\text{then} \cos.(c - \varphi) = \frac{\cos. a \cos. \varphi}{\cos. b} = \frac{\cos. a \sin. \varphi}{\sin. b \cos. A}.$$

The first value of $\cos.(c - \varphi)$ being the more simple, is to be used. The arcs $c - \varphi$ and φ being now both known, c is known.

3. To find the angle C, we have, from formula III.,

$$[\cos. b] \cos. C + [\cot. A] \sin. C = \cot. a \sin. b.$$

Here, referring to article 24, we have $M = \cos. b$, $N = \cot. A$, $P = \cot. a \sin. b$; therefore, assuming

$$\text{Tan.} \varphi = \frac{\cot. A}{\cos. b},$$

we have

$$\cos.(C - \varphi) = \cot. a \tan. b \cos. \varphi = \frac{\cot. a \sin. b \sin. \varphi}{\cot. A}.$$

From either of these formulæ the angle C is determined.

Case III. Given the sides a, b, with the included angle C, to find the angles A, B, and side c.

(1.) The angles A, B, may be found from two of Napier's analogies in article 22. Thus we have

$$\text{Tan.} \tfrac{1}{2}(A + B) = \cot. \tfrac{1}{2}C \cdot \frac{\cos. \frac{1}{2}(a - b)}{\cos. \frac{1}{2}(a + b)},$$

$$\text{Tan.} \tfrac{1}{2}(A - B) = \cot. \tfrac{1}{2}C \frac{\sin. \frac{1}{2}(a - b)}{\sin. \frac{1}{2}(a + b)}.$$

Having now half the sum and half the difference of the angles A and B, each may be found by a known process. They may be otherwise found, by subsidiary angles, from formula I.

(2.) The side c is to be found from the equation

$$[\cos. a] \cos. b + [\sin. a \cos. C] \sin. b = \cos. c.$$

Here we have $M = \cos. a$, $N = \sin. a \cos. C$, $P = \cos. c$; we therefore make $\tan. \varphi = \tan. a \cos. C$.

$$\text{Then} \cos.(b - \varphi) = \frac{\cos. c \cos. \varphi}{\cos. a};$$

$$\text{and hence} \cos. c = \frac{\cos. a \cos.(b - \varphi)}{\cos. \varphi}.$$

Case IV. Two angles A and B, and c the side between them, are given, to find the sides a, b, and angle C.

(1.) The sides a, b may be found from Napier's formulæ, article 22, thus,

$$\text{Tan.} \tfrac{1}{2}(a + b) = \tan. \tfrac{1}{2}c \cdot \frac{\cos. \frac{1}{2}(A - B)}{\cos. \frac{1}{2}(A + B)},$$

$$\text{Tan.} \tfrac{1}{2}(a - b) = \tan. \tfrac{1}{2}c \cdot \frac{\sin. \frac{1}{2}(A - B)}{\sin. \frac{1}{2}(A + B)}.$$

Half the sum and half the difference of the sides a, b being found, each is thereby determined.

(2.) The angle C is found from the formula

$$[\sin. A \cos. c] \sin. B - [\cos. A] \cos. B = \cos. C.$$

Here $M = \sin. A \cos. c$, $N = \cos. A$, $P = \cos. C$.

We now assume

$$\text{Cot.} \varphi = \tan. A \cos. c.$$

$$\text{Then} \sin.(B - \varphi) = \frac{\cos. C \sin. \varphi}{\cos. A},$$

$$\text{and} \cos. C = \frac{\cos. A \sin.(B - \varphi)}{\sin. \varphi}.$$

Case V. Two angles A, B and a side a opposite to one of them, are given, to find the sides b, c, and the angle C.

(1.) The side b is found by this formula:

$$\text{Sin.} b = \frac{\sin. a \sin. B}{\sin. A}.$$

(2.) The side c is found by this formula:

$$[\cot. a] \sin. c - [\cos. B] \cos. c = \cot. A \sin. B.$$

Here $M = \cot. a$, $N = \cos. B$, $P = \cot. A \sin. B$; we therefore assume

$$\text{Cot.} \varphi = \frac{\cot. a}{\cos. B},$$

and have $\sin.(c - \varphi) = \cot. A \tan. B \sin. \varphi$.

(3.) The angle C is found from the formula

$$[\sin. B \cos. a] \sin. C - [\cos. B] \cos. C = \cos. A.$$

Here $M = \sin. B \cos. a$, $N = \cos. B$, $P = \cos. A$.

We assume $\cot. \varphi = \tan. B \cos. a$

$$\text{Then} \sin.(c - \varphi) = \frac{\cos. A \sin. \varphi}{\cos. B}.$$

Case VI. Given the three angles A, B, C, to find the sides a, b, c.

The solution of this case has been found in art. 19.

Find $S = \frac{1}{2}(A + B + C)$,

$$\text{and } M' = \surd \left\{ \frac{\cos.(S - A) \cos.(S - B) \cos.(S - C)}{\cos. S} \right\}.$$

$$\text{Then} \cot. \tfrac{1}{2}a = \frac{M'}{\cos.(S - A)},\ \cot. \tfrac{1}{2}b = \frac{M'}{(\cos. S - B)},$$

$$\cot. \tfrac{1}{2}c = \frac{M'}{\cos.(S - C)}.$$

These formulæ are altogether analogous to those by which the angles are found from the sides. This case rarely occurs in the application of spherics to astronomy.

The analytical artifice of *subsidiary angles*, by which the formulæ are adapted to logarithmic calculation, corresponds to the resolving of an oblique spherical triangle into two right-angled triangles, by an arc of a great circle drawn from its vertex perpendicular to its base.

For the application of spherical trigonometry, see Practical Astronomy, chap. i. (vol. iv. page 63).

The treatises on trigonometry are innumerable. The most considerable is that of Cagnoli, in Italian, of which there is a French translation. On the history of trigonometry, and the progress of its improvement, the reader will find the most ample information in Delambre, *Histoire de l'Astronomie Ancienne, Histoire de l'Astronomie du Moyen Age*, and *Histoire de l'Astronomie Moderne.* See also his *Astronomie Théorique et Pratique*, vol. i. chap. 10.

TRILL, or SHAKE, in *Music*, an embellishment too frequently abused. It chiefly consists of a rapid alternate transition from the one to the other of two contiguous sounds of the musical scale, but has various modifications and names. Consult the *Méthode de Chant* of the Paris Conservatory of Music.

TRIM is the county town of the county of Meath in Ireland. It is situate upon the banks of the river Boyne, in the midst of a level, fertile, and populous district, and is distant thirty-two miles from Dublin. It is a place of great antiquity, and was formerly of such importance that several of the earlier Irish parliaments were held here. In consequence of its being made the residence and seat of government of the De Lacys, the inhabitants received many valuable privileges, which have partly come down to them at the present time. The town is built without regard to regularity, but it possesses many good private houses. The new county prison is a spacious and remarkable building, and the county court-house is also well built; but none of the other public buildings can be praised for their appearance. For several years the town has been declining, and at present it does not possess any trade or manufacture. Here are the ruins of King John's Castle, which is perhaps the most extensive in Ireland. On the opposite side of the river are the remains of a very ancient and extensive abbey. The value of the commons or landed property, and other burgage property, is between L.700 and L.800 a year. The commons are divided into burgesses and freemen's lots, and belong for life to the individuals who are either burgesses or freemen. The corporation consists of a portreeve, burgesses, and freemen, without restriction as to the numbers of the two latter. The population in 1821 amounted to 2304, and in 1831 to 3282.

TRIMAPOOR, a town of India, in the Southern Carnatic, thirty-six miles south-south-west from Tanjore. Long. 78. 55. E. Lat. 10. 21. N.

TRIMBUCK, a strong fortress of Hindustan, in the province of Aurungabad, situate near the source of the Godavery. It surrendered to the British in 1818, after a short bombardment. Long. 73. 42. E. Lat. 20. 1. N.

TRINCOMALEE, a town, fortress, and excellent harbour in the island of Ceylon, situated on the north-east of the island. It is of greater extent than Colombo, but contains fewer houses, and is much inferior in population and appearance. The fort is very strong, and commands the principal bays, particularly the entrance into the harbour. It has also a citadel, called Fort Ostenburg, erected on a cliff which projects into the sea; nor can it be attacked till after the capture of the lower fort. It was originally built by the Portuguese, from the ruins of some celebrated pagodas. In the bay the shores are so bold, and the waters so deep, that it is almost possible to step from the rocks into the vessels moored alongside. At the extremity of the rock on which the fort stands, a strong battery is erected, and there the flag-staff is placed. The harbour is good, and affords security to shipping in all seasons and weathers, being deep and capacious, and landlocked on all sides. From its convenient situation, it is of great consequence to a maritime power; for when the violent monsoon commences, all vessels on the coast of Coromandel, and the east side of the Bay of Bengal, are obliged to put to sea, and then Trincomalee is their only place of refuge. The great expectations that were formed of this place by the British government have not however been realized. Owing to the barren and unproductive nature of the surrounding country, but few inhabitants have been collected. Provisions are scarce, and there is nothing to induce merchants to settle in the town. Hence the society is almost exclusively composed of the officers of the regiments stationed here. The lower classes are chiefly Hindus from the opposite coast, and a few gold and silversmiths, who are native Ceylonese. The adjacent woods abound with wild hogs, buffaloes, and elephants, the latter being frequently shot within a mile of the town. The Portuguese were the first Europeans who were in possession of this place. It was taken from them by the Dutch, with whom it remained till the year 1782, when it was captured by the British. From them it was taken by the French under Admiral Suffrein, who restored it to the Dutch; but it was retaken by the British in 1795, and has ever since remained in their possession. Long. 81. 23. E. Lat. 8. 31. N.

TRING, a market-town of England, in the hundred of Dacorum and county of Hertford, thirty-one miles from London. It is a neatly built place, with some good houses. The church is a fine venerable Gothic structure, with a square tower; and in the chancel are some very fine monuments. It has also an endowed charity-school. There is a well-supplied market on Friday. This town is on the great road to Buckingham, and is in contact with the Grand Junction Canal, and with the London and Birmingham railroad, which last has a station here for taking up and setting down passengers. From this arrangement a great increase is anticipated, both in houses and inhabitants. The inhabitants amounted in 1811 to 1847, in 1821 to 3286, and in 1831 to 3488.

TRINGANG, a Malay town and principality on the east side of the peninsula of Malacca, between the fifth and sixth degrees of north latitude. It carries on a considerable traffic. The imports are opium, iron, steel, Bengal piece-goods, blue and other cloths, with coarse cutlery. The commodities received in return are gold-dust, pepper, and tin, the last article being imported in Malay and Buggess prows.

TRINIDAD, the largest of the windward West India Islands, is separated from the province of Venezuela by the Gulf of Paria, and at one point is not more than twenty miles from the American continent. It is situated between 10° and 11° north latitude, and 61° and 62° west longitude. The island is nearly square, being generally about fifty miles long by thirty broad; but from the furthest point (Hicacos) on the south-west to the furthest point on the north-west (Point Galera), it reaches to above ninety miles, and contains an area of 2020 square miles. It was discovered by Columbus on the 31st July 1498, and taken possession of by the Spaniards in 1588. Sir Walter Raleigh visited it in 1595, and committed some outrages in the capital. In 1797 it was captured by Sir Ralph Abercromby, and has remained a British settlement ever since. The richness of its soil, the luxuriance of its vegetation, its finely wooded hills, beautiful rivers, and magnificent landscapes, have distinguished Trinidad as the *Indian Paradise*. This island is evidently a section of the opposite continent, disjoined either by a volcanic or oceanic eruption. The same strata of earth, the same rocks and fossils, are common to both. Besides several craters and volcanoes in the island, there are two submarine volcanoes, one south of Cape de la Brea, and the other in the Bay of Meyaro. But the most remarkable phenomenon in the island is the asphaltum or pitch lake, situated on a small peninsula, and occupying the highest part of the point of land. It is nearly circular, and more than a mile and a half in length. It is remarkable for the extraordinary mutability of its surface; the small islet of the evening being often found a gulf in the morning, and this again is succeeded by another islet, adorned with the most luxuriant vegetation. The usual appearance and consistence of the asphaltum is that of pit-coal, but of a grayish colour, melting like sealing-wax, and in hot weather it is actually liquid an inch deep. It is rendered ductile by a gentle heat, and when mixed with grease or pitch, acquires fluidity. The highest mountain-range is on the north, near the coast, some parts of which reach an elevation of nearly 3000 feet. There are also chains of hills, but of less elevation, in the centre and on the south coast. They run from east to west. The island has the advantage of numerous streams, some of them navigable by small vessels. The exports amounted in 1832 to L.235,657, of which L.220,168 was for sugar and molasses. The imports for the same period amounted to L.229,697. Port of Spain, the capital, contains a population of 9860, of whom 1489 are whites. The population of the island in 1832 consisted of, whites, 3683; free blacks, 16,302; slaves, 20,265; total, 40,250. In the island there are eight free schools with 373 scholars, and twenty-two private schools with 412 scholars.

TRINITARIANS, those who believe in the Trinity; those who do not believe therein being called *Anti-trinitarians.*

TRINITY, in *Theology*, the ineffable mystery of three persons in one Godhead; the Father, Son, and Holy Spirit.

TRINITY-SUNDAY, a festival observed on the Sunday next after Whitsunday, in honour of the holy Trinity. The observation of this festival was first enjoined in the council of Arles, in the year 1260.

TRINITY *Bay*, a deep bay on the north-east coast of New Holland, between Cape Grafton and Cape Tribulation.

TRINITY *Island*, an island in the North Pacific Ocean, discovered by Captain Cook. The east point is in long. 206. 4. E. and lat. 56. 33. N.

TRINO, a city of Italy, in the province of Vercelli and kingdom of Sardinia. It is situated on the river Asta, at the point where it falls into the Po. It is a well-built place, and is divided into two parts by a long and fine street, with elegant arcades on both sides, and a canal in the middle. It has a cathedral, four monasteries, five nunneries, with each a church. Trino contains 6200 inhabitants. It has a great trade in cattle and in smoke-dried hams, which are in high repute through the whole of Italy. It was once fortified, but the defences have been neglected. Long. 18. 8. E. Lat. 45. 8. N.

TRINOBANTES, an ancient people of Britain, supposed to have occupied Middlesex and Essex.

TRINOMALEE, a town and fortress of the south of India, in the Carnatic. During the wars of the last century, this place was often taken and retaken by the contending parties. Among the natives it was always more famous for its sanctity than its strength. Its situation is on a mountain, on the top of which is a Hindu temple, from which it is believed that a subterranean fire will issue, to destroy any profane intruder. In its vicinity the British defeated the combined armies of the nizam and Hyder Aly. Trinomalee is thirty miles south-south-west from Chittapet, and thirty west from Gingee. Long. 79. 10. E. Lat. 12. 16. N.

TRIO, or TERZETTO, in *Music*, a composition for three voices or for three instruments. Among the most striking instrumental trios are those by Mozart and Beethoven for violin, viola, and violoncello, and for pianoforte, violin, and violoncello, &c. The term *trio* is also applied to a movement in $\frac{3}{4}$th time, which often follows the minuet in a piece of instrumental music.

TRIPATOOR, a town of Hindustan, in the Southern Carnatic, fifty-eight miles south-south-west from Tanjore. Long. 78. 40. E. Lat. 10. 10. N. This is also the name of a large open village in the Barramahal province, 120 miles south-west from Madras. Long. 78. 42. E. Lat. 12. 32. N.

TRIPETTY, a town in the south of India, province of the Carnatic, containing a celebrated Hindu temple, to which many thousand pilgrims annually resort. Long. 79. 3. E. Lat. 13. 31. N.

TRIPHTHONG, in *Grammar*, an assemblage or concourse of three vowels in one syllable, as *quæ.*

TRIPLE TIME, in *Music.* See MUSIC.

TRIPOD, in *Antiquity*, a famed sacred seat or stool, supported by three feet, on which the priests and sibyls were placed to render oracles. It was on the tripod that the gods were said to inspire the Pythias with that divine fury and enthusiasm with which they were seized at the delivery of their predictions.

TRIPOLI, a country of Africa, in Barbary, bounded on the north by the Mediterranean Sea, on the south by the country of the Beriberies, on the west by the kingdom of Tunis and Biledulgerid, and on the east by Egypt. It is about 925 miles along the sea-coast, but the breadth is various. Some parts of it are pretty fruitful, but that towards Egypt is a sandy desert. It had the title of a *kingdom*, but is governed by a dey. Early in the last century Tripoli shook off its dependence on the Grand Turk. In other respects the government is not essentially changed; it is still a military despotism of the most ferocious description. Its piracies are now confined to Naples, Sardinia, and other states which have no efficient navy. See BARBARY STATES.

TRIPOLI, the capital of the state of the same name in Barbary, is a considerable town, with a castle and a fort. See BARBARY STATES.

TRIPOLI, called *Tripolis of Syria*, to distinguish it from Tripoli in *Barbary*, received its name from its being anciently formed of three cities at a small distance from each other, one of which belonged to the Aradians, or ancient kingdom of Arad, the second to the Sidonians, and the third to the Tyrians, perhaps as a common mart to those maritime powers. The present town of Tripoli is built at the distance of a mile and a half from the other, upon the declivity of a hill facing the sea, in longitude 35. 50. east from Greenwich, and latitude 34. 20. north.

TRIPOLIZZA, a town of Greece, the capital of a canton of its name, as well as, under the Turkish government, of the province of the Morea. It stands in an undulated valley at the foot of Mænalus, and, according to tradition, was built from the ruins of three neighbouring towns. It is about twenty-two miles south-west from Argos, and thirty north-west from the ruins of Sparta. Before the revolution, it was a tolerably well-built place, surrounded with walls, had a citadel, four large mosques, and six Greek churches, with 12,000 inhabitants. In the contest which led to the abandonment of the Morea by the Turks, this place was the theatre of bloody events. In 1821 it was occupied by the Turks and Mahommedan Albanians, when it was besieged from August to October by the Greek leader Colocotroni. The Albanians entered into a secret treaty with the Greek commander; and on the 5th of October, at an early hour, the besiegers made an assault, favoured as they were by the traitors in the garrison. The battle raged during the whole day, the Turks defending, from house to house, their positions with great firmness, till fires were kindled in several parts; and the Greeks, being fully masters, put to death the Turks, without distinction of age or sex, to the number of more than 6000 individuals. The plunder of this city was one of the means by which the Greeks were enabled to carry on the war, and to make themselves masters of the Peloponnesus. As Ibrahim Pacha with his Egyptian forces was in possession of Navarino in 1825, he also took possession of Tripolizza, and when he abandoned the Morea, he left this town a heap of ruins. The country around it is fertile; and if a good government should be established in the country, Tripolizza may yet revive, and become a flourishing city.

TRIPONTARY, a town of Hindustan, in the territories of Cochin, ten miles from the port of Cochin. Long. 76. 20. E. Lat. 9. 57. N.

TRIPOSSOOR, a town of Hindustan, in the Carnatic, thirty miles west by north from Madras. It was taken by Hyder in 1780, and was retaken in 1781 by the British. Long. 78. 57. E. Lat. 13. 9. N.

TRIREMIS, in *Antiquity*, a galley with three ranks of oars on a side.

TRISMEGISTUS, an epithet or surname given to one of the two Hermeses.

TRISYLLABLE, in *Grammar*, a word consisting of three syllables.

TRITANY, a town of Southern India, in the Carnatic, forty-five miles west by north from Madras. Long. 79. 45. E. Lat. 13. 9. N.

TRITON, a sea-demigod, held by the ancients to be an officer or trumpeter of Neptune, attending on him, and carrying his orders from sea to sea.

TRITONE, in *Music*, a major fourth, such as from F to B.

TRITURATION, the act of reducing a solid body into a subtile powder; called also *pulverisation* and *levigation*.

TRIUMPH, a public and solemn honour conferred by the ancient Romans on a victorious general, by allowing him a magnificent entry into the city. The greater triumph, called also *curulis*, or simply the triumph, was decreed by the senate to a general, upon the conquering of a province, or gaining a signal victory. The day appointed for the ceremony being arrived, scaffolds were erected in the forum and circus, and all the other parts of the city where they could best behold the pomp. The senate went to meet the conqueror without the gate called *Capena* or *Triumphalis*, and marched back in order to the Capitol; the ways being cleared and cleansed by a number of officers and tipstaffs, who drove away such as thronged the passage or straggled up and down. The general was clad in a rich purple robe, interwoven with figures of gold, setting forth his great exploits; his buskins were set with pearl; and he wore a crown, which at first was only laurel, but afterwards gold; in one hand he bore a branch of laurel, and in the other a truncheon. He was carried in a magnificent chariot, adorned with ivory and plates of gold, drawn usually by two white horses; though sometimes by other animals, as that of Pompey, when he triumphed over Africa, by elephants, that of Mark Antony by lions, that of Heliogabalus by tigers, that of Aurelian by deer. His children were at his feet, and sometimes on the chariot horses. The procession was led by the musicians, who played triumphal pieces in praise of the general. These were followed by young men, who led the victims to the sacrifice, with their horns gilded, and their heads adorned with ribbands and garlands. Next came the carts and waggons, loaded with all the spoils taken from the enemy, together with their horses, chariots, &c. These were followed by the kings, princes, and generals, who had been taken captives, loaded with chains. Next appeared the triumphal chariot, before which, as it passed, they all along strewed flowers, and the people with loud acclamations called out *Io triumphe!* The chariot was followed by the senate, clad in white robes, and the senate by such citizens as had been set at liberty or ransomed; and the procession was closed by the priests and their officers and utensils, with a white ox led along for the chief victim. In this order they proceeded through the triumphal gate, along the Via Sacra, to the Capitol, where the victims were slain. In the mean time all the temples were open, and all the altars loaded with offerings and incense; games and combats were celebrated in the public places, and the city became a scene of general festivity. The less splendid form of a triumph was called an *Ovation;* a term supposed to have been derived from *ovis*, because on such an occasion sheep, and not oxen, were usually sacrificed. The procession commonly began at the Albanian Mount, from whence the general with his retinue made his entry into the city. He walked on foot, wearing a garland of myrtle, and was attended by a band of music.

TRIUMVIR, one of three persons who govern absolutely, and with equal authority, in a state. It is chiefly applied to the Roman government. Cæsar, Pompey, and Crassus, were the first triumvirs, who divided the government among them. There were also other officers so called; as the triumviri or tresviri capitales, who were the keepers of the public gaol. They had the office of punishing malefactors, for which purpose they employed eight lictors.

TRIVADY, a town of Southern India, in the province of the Carnatic, containing a large temple, which serves as a citadel. Long. 79. 45. E. Lat. 11. 42. N.

TRIVALENOOR, a town of Southern India, in the Carnatic, thirty-five miles west by south from Pondicherry. Long. 79. 30. E. Lat. 11. 51. N.

TRIVANDAPATAM, a town of Hindustan, in the province of Travancore, sixty miles north-west from Cape Comorin. Long. 76. 55. E. Lat. 8. 27. N.

TRIVATOOR, a town of Southern India, in the Carnatic, sixty miles south-west from Madras. Long. 79. 40. E. Lat. 12. 38. N.

TRIVICARY, a village of Southern India, in the Carnatic, situated on the north bank of the Villenoor river, about fifteen miles west by north from Pondicherry. This was once a place of much greater extent, but is now greatly decayed.

TRIVIDY, a town of Southern India, in the Carnatic, twenty-four miles south-west from Pondicherry. Long. 79. 40. E. Lat. 11. 44. N.

TROAS, a country of Phrygia, in Asia Minor, of which Troy was the capital. When Troas is taken for the whole kingdom of Priam, it may be said to contain Mysia and Phrygia Minor; but if it is taken for that part of the country where Troy was situated, its extent is confined within very narrow limits. Troas was anciently called Dardania.

TROBRIAND Islands, a cluster forming part of the archipelago of Louisiade, discovered by D'Entrecasteaux. The most northern point is in long. 151. 8. E. lat. 8. 24. S.

TROCHÆUS, in *Prosody*, a foot consisting of a long and a short syllable.

TROCTOU, a small island in the Eastern Seas, near the coast of Queda. Long. 99. 33. E. Lat. 6. 30. N.

TROGLODYTES, an ancient people of Ethiopia, who are said to have lived in caves under ground. Pomponius Mela gives a strange account of the Troglodytes. He affirms that they did not so properly speak, as shriek; and that they lived on serpents.

TROGUS Pompeius, a Latin universal historian to the time of Augustus Cæsar, of whom we have only an abridgement by Justin, flourished about 41 b. c.

TROITSK, a town of Asiatic Russia, in the government of Orenburg. It is tolerably well built, having straight and regular streets, and contains about 500 houses. It has wooden fortifications, which form a square, and which are flanked with towers, and encompassed by a ditch and glacis. It is a commercial place, being an emporium for the trade with the Asiatic tribes. The trade is carried on in the exchange, a large square, built on the opposite side of the river Oui or Ouk, which flows by the city. Long. 55. 30. E. Lat. 54. 15. N. This is also the name of another town of Asiatic Russia, situated about ninety miles to the west of the former, and containing 3000 inhabitants, who are mostly engaged in cultivation.

TROITSKO Sauskaia, a fortress of Asiatic Russia, situated near the Chinese frontier, on the Kiachta, where is fixed the court for managing the discussions that arise with the Chinese. Troitsko is 345 miles south of Irkoutsk.

TROLLHATTEN, a town of Sweden, in the department of Elfsborg and province of East Gothland. It is peculiarly situated on the river Gothelf or Gothelbe, which flows from the lake of Werner, and falls into the sea near Gottenburg, and here forms a very great cataract, or rather a succession of cascades. Before the stream reaches this spot, it is compressed, by the narrow passage it has rced through the rocks, into a state not unlike that in hich water rushes from a pipe, and thus has a surprising locity. It falls by four cascades about 100 feet; and as e lower of these cascades slopes at the bottom, the whole shes down with such impetuosity that the noise which it akes is heard at the distance of twelve miles. As the shores this lake produce vast quantities of iron and of timber, ich would become of increased value if the falls could be oided, the government was induced to construct a canal, ich was begun in 1793 and completed in 1800, at a eat expense for so poor a country. This canal is a pro- gious work, and though scarcely more than two English les in length, has nine locks, by which vessels descend ore than 100 feet. Each of these locks is twenty-two et long and seven feet wide. More than 3000 vessels ssed it in one year, paying tolls, which produce a good re- rn for the money expended. A project is now in pro- ess which will make this canal still more beneficial. nals are forming to unite the lake of Werner with the eilmar and Maler Lakes, by which, when accomplished, ssels will be enabled to pass from Stockholm to Gotten- rg, across the kingdom, and thus avoid the passage of e sound and the Danish tolls. Trollhatten was only a lage when the works began, but is now an increasing wn, and has several iron-works, whose machinery is set motion by the falls. It likewise has some considerable ablishments for building ships.

TROMBONE. See MUSIC.

TROMP, MARTIN HAPPERTZ VAN, a celebrated Dutch miral, was born at the Baille, in Holland. He raised nself by his merit, after having distinguished himself on ny occasions, especially at the famous engagement near braltar in 1607. He passed for one of the greatest sea- en who till that time had appeared in the world; and was clared admiral of Holland, even by the advice of the ince of Orange. In that character he defeated a large anish fleet in 1630, and gained thirty-two other victories sea; but was killed when under deck, in an engagement th the English, in 1653.

TRON, ST, a city of the Netherlands, in the province of mburg and arrondissement of Hasselt. It is situated on e river Mecselbeek, and on the road from Liege to ussels. It contains 7300 inhabitants, who are employed making fire-arms, swords, and cutlery; and the females ke some thread-lace. St Tron is celebrated for a battle ght there in 1793, in which the French were defeated the Austrians. Long. 6. 9. E. Lat. 50. 45. N.

TRONAGE, an ancient customary duty or toll, for the ighing of wool. According to Fleta, *trona* is a beam to igh with, mentioned in the stat. Westm. 2, cap. 25. And onage was used for the weighing of wool in a staple or pub- mart, by a common trona or beam; which, for the tron- e of wool in London, was fixed at Leadenhall. The ayor and commonalty of London were ordained keepers of e beams and weights for weighing merchants' commodi- s, with power to assign clerks and porters, &c. of the eat beam and balance; which weighing of goods and res is called *tronage;* and on pain of forfeiture, no stranger s to buy any goods in London before they were weighed the king's beam.

TROON, a thriving town in Ayrshire, with an excellent tural harbour, having nineteen feet of water at the lowest b. In 1831 the population amounted to about 1000 per- ns. See AYRSHIRE.

TROPHONIUS'S CAVE, or *Oracle*, a cave near Leba- a in Bœotia, between Helicon and Chæronea (Strabo); so lled from Trophonius, an enthusiastic diviner, who, des- nding into this cave, pretended to give answers and pro- unce oracles, and was hence called *Jupiter Trophonius.* ich as entered this cave never afterwards smiled; and hence e proverbial saying of a man who has lost his mirth, that he is come out of Trophonius's cave. Dr Clarke found the cave choked up with stones.

TROPHY (*Tropæum*), among the ancients, a monument of victory.

TROPICS. See GEOGRAPHY.

TROPPAU, a circle of the Austrian principality of Moravia, commonly denominated the duchy. It is situated between the rivers Oppa and Oder, and contains three cities, one market-town, and 78,600 inhabitants. The capital is the city of the same name, a place well built and fortified, and the seat of a provincial judicature. It contains 880 houses, with 10,760 inhabitants, carrying on manufactures of woollen goods, paper, soap, and fire-arms. Long. 12. 45. 25. E. Lat. 49. 50. 1. N.

TROSACHS, the name given to that romantic glen which separates Loch Kateran (Katrine) from Loch Achray, in the Western Highlands of Perthshire. The name signifies in Gaelic the Bristled Territory; a signification perfectly applicable to the confused mass of abrupt crags which, in some convulsion of nature, has been separated from the neighbouring mountains of Ben Vennu and Ben-An. These crags are of the most extraordinary and fantastic forms; and being covered with a profusion of trees and shrubs, the diversity of hues which they yield, mixed with the shades of the deep ravines, and the highly picturesque and wooded acclivity of the lofty Ben-An, gives a depth and wildness to the pass, not to be equalled, it is supposed, in the world. This rugged and narrow defile is about one mile and a half in length, and was first rendered an object of popular attention by Sir Walter Scott, in his poem of the Lady of the Lake. The modern road for the use of tourists, which passes through it, has in a great degree marred its solitude.

TROUBADOURS, poets that flourished in Provence during the middle ages. They wrote poems on love and gallantry; on the illustrious characters and remarkable events of the times; satires, which were chiefly directed against the clergy and monks; and a few didactic pieces. The troubadours were great favourites in different courts, diffused a taste for their language and for poetry over Europe, which was about that time sunk in ignorance and rudeness. An "Histoire des Troubadours," in 3 vols. 12mo, was published by Millot; but it has been entirely superseded by the more recent labours of Raynouard and Diez.

TROVER, in *Law*, an action that a man has against one that, having found any of his goods, refuses to deliver them upon demand.

TROWBRIDGE, a market-town in the hundred of Melksham and county of Wilts, ninety-nine miles from London. It is situated upon an eminence near the river Ware, a branch of the river Avon, and is irregularly built. The principal street is spacious and well built; but the minor streets are narrow, and contain many ancient houses. The town is paved and lighted with gas. The church is a spacious and well-built edifice, having a large tower at the west end, surmounted by a spire. There are also places of worship for dissenters. The inhabitants are chiefly occupied in the manufacture of woollen cloth, mostly kerseymeres and superfine broad cloth. The population amounted in 1821 to 9545, and in 1831 to 10,863.

TROWERT ISLAND, a small island in the Eastern Seas, near the south coast of Java. Long. 105. 45. E. Lat. 7. 2. S.

TROY, or TROJA, the capital city of Troas, or, according to others, a country of which Ilium was the capital. It was built on a small eminence near Mount Ida, and the promontory of Sigæum, at the distance of about four miles from the sea-shore. Dardanus, the first king of the country, built it, and called it *Dardania;* and from Tros, one of his successors, it was called *Troja;* and from Ilus, *Ilion.* This city has been celebrated by Homer and Virgil.

Troy Weight.

A description of the plain of Troy by Chevalier has been published in the third volume of the Philosophical Transactions of the Royal Society of Edinburgh.[1] The city of Troy, according to him, stood on the present site of the modern village of Bournabashi, which is situated four leagues from the sea, on the side of an eminence, at the termination of a spacious plain, the soil of which is rich and of a blackish colour. Close to the village is to be seen a marsh covered with tall reeds; and the situation is impregnable on all sides except at Erin (Homer's ἐρινεὸς), the *hill of wild fig-trees,* which extended between the Scæan gate and the sources of the Scamander. In the plain there are several conical mounds or barrows, some of them a hundred feet in diameter at the base; and these the author maintains to be the identical tombs raised over the ashes of the heroes of the Trojan war. Since Chevalier's dissertation appeared, this plain has been investigated by Mr Morritt, Sir William Gell, Dr Clarke, Mr Hobhouse, Mr Acland, and several other travellers and writers. Dr Clarke traversed the ground in different directions seventeen times. He rejects the hypothesis of Chevalier, and, reasoning from the authority of Strabo, and from the site of New Ilium, which he ascertained by inscriptions found among ruins, he fixes the situation of Troy four or five miles to the northward of Bournabashi, near a sluggish rivulet, called Califat Osmack, which he considers to be the Simois. The name of the Scamander is still preserved in the Mender, the most considerable stream in the district, rising in Mount Ida, as described by Homer; and the Thymbrius is still preserved in the Thymbrek. Dr Clarke also finds objects corresponding to the Callicolone, the tomb of Ilus, and the Throsmos or mound of the plain. But very strong objections have been stated to his opinions by Mr Hobhouse and others; and, upon the whole, the more this subject is investigated, the more insuperable difficulties seem to present themselves to any attempt to identify the places and objects alluded to by the poet.

TROY *Weight*, one of the most ancient of the different kinds used in Britain. The ounce of this weight was brought from Grand Cairo in Egypt, about the time of the crusades, into Europe, and first adopted in *Troyes,* a city of Champagne; whence the name.

The pound *English* Troy contains twelve ounces, or 5760 grains. It was formerly used for every purpose, and is still retained for weighing gold, silver, and jewels; for compounding medicines; for experiments in natural philosophy; and for comparing different weights with each other.

Scotish TROY-*Weight* was established in the year 1618, by James VI., who enacted that only one weight should be used in Scotland, viz. the French Troy stone of 16 pounds, and 16 ounces in the pound. The pound contains 7600 grains, and is equal to 17 oz. 6 dr. avoirdupois. The cwt. or 112 lb. avoirdupois contains only 103 lb. 2½ oz. of this weight, though generally reckoned equal to 104 lb. This weight is nearly, if not exactly, the same as that of Paris and Amsterdam; and is generally known by the name of *Dutch weight.* Though prohibited by the articles of union, it continued to be used in weighing iron, hemp, flax, most Dutch and Baltic goods, meal, butcher-meat, unwrought pewter and lead, and some other articles. See WEIGHTS and MEASURES.

TROYES, an arrondissement of the department of the Aube, in France. It extends over 589 square miles, is divided into nine cantons, and these into 121 communes, containing, in 1836, 90,923 inhabitants. The chief city, of the same name, is also the capital of the department. It is situated on the river Seine, and is the seat of a bishop, and of the departmental courts of law and revenue. The cathedral, dedicated to St Peter, is a fine old and large Gothic building. There are other four churches, among which that of St Martin is distinguished by remarkably fine painted glass windows. Troyes is now a place of great manufacturing industry, making large quantities of woollen and cotton goods. Much linen is made and admirably bleached. It has also establishments for making glass, paper, leather, brandy, and vinegar. Its traffic is very considerable, and it has an appearance of great prosperity. It was at one period a capital of the duchy of Burgundy, where the states assembled. It is stated to have then contained upwards of 60,000 inhabitants. It had in 1836 a population of 25,563. Long. 3. 59. 29. E. Lat. 48. 18. 15. N.

TRUMPET, a musical instrument, the most noble of all portable ones of the wind kind; used chiefly in war, among the cavalry, to direct them in the service. As to the invention of the trumpet, some Greek historians ascribe it to the Tyrrhenians; but others, with greater probability, to the Egyptians, from whom it might have been transmitted to the Israelites. The trumpet was not in use among the Greeks at the time of the Trojan war, though it was in common use in the time of Homer. According to Potter (*Arch. Græc.* vol. ii. cap. 9), before the invention of trumpets, the first signals of battles in the primitive wars were lighted torches; to these succeeded shells of fishes, which were sounded like trumpets. And when the trumpet became common in military use, it may well be imagined to have served at first only as a rough and noisy signal of battle, like that at present in Abyssinia and New Zealand, and perhaps with only one sound. But even when more notes were produced from it, so noisy an instrument must have been an unfit accompaniment for the voice and poetry; so that it is probable the trumpet was the first solo instrument in use among the ancients.

TRUMPET, ARTICULATE, comprehends both the *speaking* and the *hearing* trumpet, is by much the most valuable instrument, and has, in one of its forms, been used by people among whom we should hardly have expected to find such improvements. That the *speaking trumpet,* of which the object is to increase the force of articulate sounds, should have been known to the ancient Greeks, can excite no wonder; and therefore we easily admit the accounts which we read of the horn or trumpet, with which Alexander addressed his army, as well as of the whispering caverns of the Syracusan tyrant. But that the natives of Peru were acquainted with this instrument, will probably surprise many of our readers. The fact, however, seems incontrovertible.

In the History of the Order of Jesuits, published at Naples in 1601 by Beritaria, it is said, that in the year 1595 a small convent of that order in Peru, situated in a remote corner, was in danger of immediate destruction by famine. One evening the superior, Father Samaniac, implored the help of the cacique. Next morning, on opening the gate of the monastery, he found it surrounded by a number of women, each of whom carried a small basket of provisions. He returned thanks to heaven for having miraculously interposed, by inspiring the good people with pity for the distress of his friars. But when he expressed to them his wonder how they came all to be moved as if by mutual agreement with these benevolent sentiments, they told him it was no such thing; that they looked upon him and his countrymen as a pack of infernal magicians, who by their sorceries had enslaved the country, and had bewitched their good cacique, who hitherto had treated them with kindness and attention, as became a true worshipper of the sun; but that the preceding evening at sunset he had ordered the inhabitants of such and such villages, about six miles off, to come that morning with provisions to this nest of wizards. The superior asked them in what manner the governor had warned so many of them in so short a time, at such a distance from his own residence. They told him that it was by the trumpet; and that every person heard at his own door the distinct terms of the order. The father had heard nothing; but they told him that none heard the trumpet but the inhabitants of the villages to which it was directed. This is a piece of very curious information; but, after allowing a good deal to the exaggeration of the reverend Jesuits, it cannot, we think, be doubted that the Peruvians actually possessed this stentorophonic art. For we may observe that the effect described in this narration resembles what we *now know* to be the effect of speaking trumpets, while it is unlike what the inventor of such a tale would naturally and ignorantly say. Till speaking trumpets were really known, we would expect the sound to be equally diffused on all sides, which is not the case; for it is much stronger in the line of the trumpet than in any direction very oblique to it.

---

[1] Chevalier's work, written in French, was translated into English, and illustrated with notes, by Professor Dalzel. Edinb. 1791, 4to. It soon afterwards appeared in a German translation, to which Heyne contributed a preface, and other additions: "Beschreibung der Ebene von Troja," u. s. w. Leipzig, 1792, 8vo. This was followed by "Die Ebene von Troja, nach dem Grafen Choiseul Gouffier, und andern neuern Reisenden; nebst einer Abhandlung des Hern. Major Müller in Göttingen, und Erläuterungen über den Schauplatz der Ilias, und die darauf vorgefallnen Begebenheiten, von Carl Gotthold Lenz." Neu-Strelitz, 1798, 8vo. Nor must we here overlook a short but learned dissertation of Spohn, "De Agro Trojano in Carminibus Homericis descripto." Lipsiæ, 1814, 8vo. A more recent work on the subject was published by Mr Maclaren: "A Dissertation on the Topography of the Plain of Troy, including an Examination of the Opinions of Demetrius, Chevalier, Dr Clarke, and Major Rennell." Edinb. 1822, 8vo.

About the middle of the seventeenth century, Athanasius Kircher turned his attention to the philosophy of sound, and in different works threw out many useful and scientific hints on the construction of speaking trumpets; but his mathematical illustrations were so vague, and his own character of inattention and credulity so notorious, that for some time these works did not attract the notice to which they were well entitled.

About the year 1670, Sir Samuel Morland, a gentleman of great ingenuity and science, directed his attention to this subject, and proposed as a question to the Royal Society of London, What is the best form for a speaking trumpet? which he called a stentorophonic horn. He accompanied his demand with an account of his own notions on the subject (which he acknowledged to be very vague and conjectural), and an exhibition of some instruments constructed according to his views. They were in general very large conical tubes, suddenly spreading at the very mouth to a greater width. Their effect was really wonderful. They were tried in St James's Park; and his majesty, King Charles II., speaking in his ordinary colloquial pitch of voice through a trumpet only five and a half feet long, was clearly and most distinctly heard at the distance of 1000 yards. Another person, selected we suppose for the loudness and distinctness of his voice, was perfectly understood at the distance of four miles and a half. The fame of this instrument soon spread. Morland's principles were refined, considering the novelty of the inquiry, and differed considerably from Father Kircher's. The aerial undulations (for he speaks very accurately concerning the nature of sound) endeavour to diffuse themselves in spheres, but are stopped by the tube, and therefore reundulate towards the axis like waves from a bank; and meeting in the axis, they form a strong undulation a little farther advanced along the tube, which again spreads, is again reflected, and so on, till it arrives at the mouth of the tube greatly magnified, and then it is diffused through the open air in the same manner as if all proceeded from a very sonorous point in the centre of the wide end of the trumpet. The author distinguishes with great judgment between the prodigious reinforcement of sound in a speaking trumpet and that in the musical trumpet, bugle-horn, conch-shell, &c.; and shows that the difference consists in the violence of the first sonorous agitation, which can be produced by us only on a very small extent of surface. The mouth-piece diameter, therefore, of the musical trumpet must be very small, and the force of blast very considerable. Thus one strong but simple undulation will be excited, which must be subjected to the modifications of harmony, and will be augmented by using a conical tube.[1] But a speaking trumpet must make no change on the nature of the first undulations; and each point of the mouth-piece must be equally considered as the centre of sonorous undulations, all of which must be reinforced in the same degree, otherwise all distinctness of articulation will be lost. The mouth-piece must therefore take in the whole of the mouth of the speaker.

When Sir Samuel Morland's trumpet came to be generally known on the continent, it was soon discovered that the speaker could be heard at a great distance only in the line of the trumpet; and this circumstance was by a Mr Cassegrain (*Journ. des Sçavans*, 1672, p. 131) attributed to a defect in the principle of its construction, which he said was not according to the laws of sonorous undulations. He proposed a conoid formed by the revolution of a hyperbola round its assymptote as the best form. A Mr Hase of Wirtemberg, on the other hand, proposed a parabolic conoid, having the mouth of the speaker placed in the focus. In this construction he plainly went on the principle of a reflection similar to that of the rays of light; but this is by no means the case. The effect of the parabola will be to give one reflection, and in this all the circular undulations will be converted into plane waves, which are at right angles to the axis of the trumpet. But nothing hinders their subsequent diffusion; for it does not appear that the sound will be enforced, because the agitation of the particles on each wave is not augmented.

The subject is exceedingly difficult. We do not fully comprehend on what circumstance the affection or agitation of our organ, or simply of the membrana tympani, depends. A more violent agitation of the same air, that is, a wider oscillation of its particles, cannot fail to increase the impulse on this membrane. The point therefore is to find what concourse of feeble undulations will produce or be equivalent to a great one. The reasonings of all these restorers of the speaking trumpet are almost equally specious, and each point out some phenomenon which should characterise the principle of construction, and thus enable us to say which is most agreeable to the procedure of nature. Yet there is hardly any difference in the performance of trumpets of equal dimensions made after these different methods.

The propagation of light and that of elastic undulations seem to require very different methods of management. Yet the ordinary phenomena of echoes are perfectly explicable by the acknowledged laws either of optics or acoustics; still however there are some phenomena of sound which are very unlike the genuine results of elastic undulations. If sounds are propagated spherically, then what comes into a room through a small hole should diffuse itself from that hole as round a centre, and it should be heard equally well at twelve feet distance from the hole in every direction. Yet it is very sensibly louder when the hearer is in the straight line drawn from the sonorous body through the hole. A person can judge of the direction of the sounding body with tolerable exactness. Cannon discharged from the different sides of a ship are very easily distinguished, which should not be the case by the Newtonian theory; for in this the two pulses on the ear should have no sensible difference.

---

[1] Accordingly the sound of the bugle-horn, of the musical trumpet, or the French horn, is prodigiously loud, when we consider the small passage through which a moderate blast is sent by the trumpeter.

The most important fact for our purpose is this: an echo from a small plane surface in the midst of an open field is not heard, unless we stand in such a situation that the angle of reflected sound may be equal to that of incidence. But by the usual theory of undulations, this small surface should become the centre of a new undulation, which should spread in all directions. If we may make an analogous experiment on watery undulations, by placing a small flat surface so as to project a little above the water, and then drop in a small pebble at a distance, so as to raise one circular wave, we shall observe, that when this wave arrives at the projecting plane, it is disturbed by it, and this disturbance spreads from it on all sides. It is indeed sensibly stronger in that line which is drawn from it at equal angles with the line drawn to the place where the pebble was dropped. But in the case of sound, it is a fact, that if we go to a very small distance on either side of the line of reflection, we shall hear nothing.

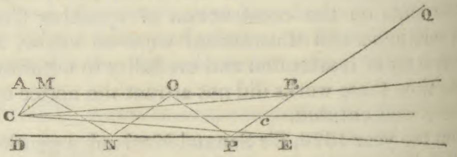
Here then is a fact, that whatever may be the nature of the elastic undulations, sounds are reflected from a small plane in the same manner as light. We may avail ourselves of this fact as a mean for enforcing sound, though we cannot explain it in a satisfactory manner. We should expect from it an effect similar to the hearing of the original sound along with another original sound coming from the place from which this reflected sound diverges. If therefore the reflected sound or echo arrives at the ear in the same instant with the original sound, the effect will be doubled; or at least it will be the same with two simultaneous original sounds. Now we know that this is in some sense equivalent to a stronger sound; for it is a fact, that a number of voices uttering the same or equal sounds is heard at a much greater distance than a single voice. How this happens, we cannot perhaps explain by mechanical laws, or assign the exact proportion in which ten voices exceed the effect of one voice; or the proportion of the distances at which they seem equally loud. We may therefore, for the present, suppose that two equal voices at the same distance are twice as loud, three voices three times as loud, &c. Therefore, if, by means of a speaking trumpet, we can make ten equal echoes arrive at the ear at the same moment, we may suppose its effect to be to increase the audibility ten times; and we may express this shortly by calling the sound ten times louder or more intense.

But we cannot do this precisely. We cannot by any contrivance make the sound of a momentary snap, and those of its echoes, arrive at the ear in the same moment, because they come from different distances. But if the original noise be a continued sound, a man's voice, for example, uttering a continued uniform tone, the first echo may reach the ear at the same moment with the second vibration of the larynx, the second echo along with the third vibration, and so on. It is evident, that this will produce the same effect. The only difference will be, that the articulations of the voice will be made indistinct, if the echoes come from very different distances. Thus, if a man pronounce the syllable *taw*, and ten successive echoes are made from places which are ten feet farther off, the tenth part of a second (nearly) will intervene between hearing the first and the last. This will give it the sound of the syllable *thaw*, or perhaps *raw*, because *r* is the repetition of *t*. Something like this occurs when, standing at one end of a long line of soldiers, we hear the muskets of the whole line discharged in one instant. It seems to us the sound of a running fire.

The aim therefore in the construction of a speaking trumpet may be, to cause as many echoes as possible to reach a distant ear without any perceptible interval of time. This will give distinctness, and something equivalent to loudness. Pure loudness arises from the violence of the single aerial undulation. To increase this may be the aim in the construction of a trumpet; but we are not sufficiently acquainted with the mechanism of these undulations to bring this about with certainty and precision; whereas we can procure this accumulation of echoes without much trouble, since we know that echoes are, in fact, reflected like light. We can form a trumpet so that many of these lines of reflected sound shall pass through the place of the hearer. We are indebted to Mr Lambert of Berlin for this simple and popular view of the subject; and shall here give an abstract of his most ingenious Dissertation on Acoustic Instruments, published in the Berlin Memoirs for 1763.

Sound naturally spreads in all directions; but we know that echoes or reflected sounds proceed almost strictly in certain limited directions. If therefore we contrive a trumpet in such a way that the lines of echo shall be confined within a certain space, it is reasonable to suppose that the sound will become more audible in proportion as this diffusion is prevented. Therefore, if we can oblige a sound which, in the open air, would have diffused itself over a hemisphere, to keep within a cone of 120°, we should expect it to be twice as audible within this cone. This will be accomplished by making the reflections such that the lines of reflected sound shall be confined within this cone. We here suppose that nothing is lost in the reflection. Let us examine the effect of a cylindrical trumpet.

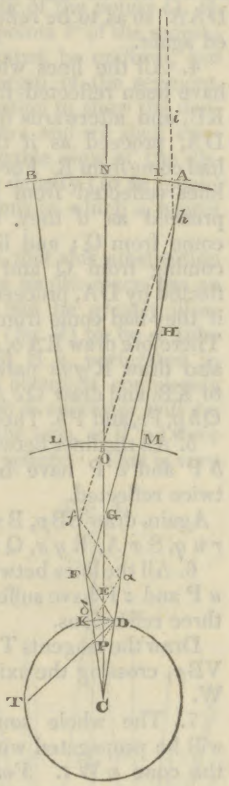
Fig. 1.



Let the trumpet be a cylinder ABED (fig. 1), and let C be a sounding point in the axis. It is evident that all the sound in the cone BCE will go forward without any reflection. Let CM be any other line of sound, which we may, for brevity's sake, call a *sonorous* or *phonic line*. Being reflected in the points M, N, O, P, it is evident that it will at last escape from the trumpet in a direction PQ, equally diverging from the axis with the line CM. The same must be true of every other sonorous line. Therefore the echoes will all diverge from the mouth of the trumpet, in the same manner as they would have proceeded from C without any trumpet. Even supposing, therefore, that the echoes are as strong as the original sound, no advantage is gained by such a trumpet, but that of bringing the sound forward from C to *c*. This is quite trifling when the hearer is at a distance. Yet we find that sounds may be heard at a very great distance, at the end of long, narrow, cylindrical, or prismatical galleries. It is known that a voice may be distinctly heard at the distance of several hundred feet in the Roman aqueducts, whose sides are perfectly straight and smooth, being plastered with stucco. The smooth surface of the still water greatly contributes to this effect. Cylindrical or prismatical trumpets must therefore be rejected.

Let the trumpet be a cone BCA (fig. 2), of which CN is the axis, DK a line perpendicular to the axis, and DFHI the path of a reflected sound in the plane of the axis. The last angle of reflection IHA is equal to the last angle of incidence FHC. The angle BFH, or its equal CFD, is equal to the angles FHD and FCH; that is, the angle of incidence CFD exceeds the next angle of incidence FHC by the angle FCD, that is, by the angle of the cone. In like manner, FDH exceeds CFD by the same angle FCD. Thus every succeeding angle, either of incidence or reflection, exceeds the next by the angle of the cone. Call the angle of the cone a, and let b be the first angle of incidence PDC. The second, or DFC, is $b-a$. The third, or FHC, is $b-2a$, &c.: and the nth angle of incidence or reflection is $b-n\,a$, after n reflections. Since the angle diminishes by equal quantities at each subsequent reflection, it is plain, that whatever be the first angle of incidence, it may be exhausted by this diminution; namely, when n times a exceeds or is equal to b. Therefore, to know how many reflections of a sound, whose first incidence has the inclination b, can be made in an infinitely extended cone, whose angle is a, divide b by a; the quotient will give the number n of reflections, and the remainder, if any, will be the last angle of incidence or reflection less than a. It is very plain, that when an angle of reflection IHA is equal to or less than the angle BCA of the cone, the reflected line HI will no more meet with the other side CB of the cone.

Fig. 2.



We may here observe, that the greatest angle of incidence is a right angle, or 90°. This sound would be reflected back in the same line, and would be incident on the opposite side in an angle $= 90^\circ - a$, &c.

Thus we see that a conical trumpet is well suited for confining the sound; for, by prolonging it sufficiently, we can keep the lines of reflected sound wholly within the cone. And when it is not carried to such a length as to do this, when it allows the sounding line GH, for example, to escape without farther reflection, the divergency from the axis is less than the last angle of reflection BFH by half the angle BCA of the cone. Let us see what is the connection between the length and the angle of ultimate reflection.

We have sin. $(b-a)$: sin. $b =$ CD : CF, and CF $=$ CD $\times \frac{\text{sin. } b}{\text{sin. }(b-a)}$, and sin. $(b-2\,a)$: sin. $(b-a) =$ CF : CH, and CH $= \text{CF} \times \frac{\text{sin. }(b-a)}{\text{sin.}(b-2\,a)} = \text{CD} \times \frac{\text{sin. } b}{\text{sin.}(b-a)} \times \frac{\text{sin.}(b-a)}{\text{sin.}(b-2a)} = \text{CD} \times \frac{\text{sin. } b}{\text{sin.}(b-2\,a)}$, &c.

Therefore if we suppose X to be the length which ll give us n reflections, we shall have $\text{X} = \text{CD} \times \frac{\text{sin. } b}{\text{sin.}(b-n\,a)}$. Hence we see that the length increases as e angle $(b-n\,a)$ diminishes; but is not infinite, unless a is equal to b. In this case, the immediately preceding angle of reflection must be a, because these angles have the common difference a. Therefore the last reflected sound was moving parallel to the opposite side of the cone, and cannot again meet it. But though we cannot assign the length which will give the nth reflection, we can give the length which will give the one immediately preceding, whose angle with the side of the cone is a. Let Y be this length. We have $\text{Y} = \text{CD} \times \frac{\text{sin. } b}{\text{sin. } a}$. This length will allow every line of sound to be reflected as often, saving once, as if the tube were infinitely long. For suppose a sonorous line to be traced backwards, as if a sound entered the tube in the direction $i\,h$, and were reflected in the points h, f, d, D, the angles will be continually augmented by the constant angle a. But this augmentation can never go farther than $90^\circ + \frac{1}{2}\,a$. For if it reaches that value at D, for instance, the reflected line DK will be perpendicular to the axis CN; and the angle ADK will be equal to the angle DKB, and the sound will come out again. This remark is of importance on another account.

Now, suppose the cone to be cut off at D by a plane perpendicular to the axis, KD will be the diameter of its mouth-piece; and if we suppose a mouth completely occupying this circle, and every point of the circle to be sonorous, the reflected sounds will proceed from it in the same manner as light would from a flame which completely occupies its area, and is reflected by the inside of the cone. The angle FDA will have the greatest possible sine when it is a right angle, and it never can be greater than ADK, which is $= 90^\circ + \frac{1}{2}\,a$. And since between $90^\circ + \frac{1}{2}\,a$, and $90^\circ - \frac{1}{2}\,a$, there must fall some multiple of a, call this multiple b. Then, in order that every sound may be reflected as often as possible, saving once, we must make the length of it $\text{X} = \text{CD} \times \frac{\text{sin. } b}{\text{sin. } a}$.

Now, since the angle of the cone is never made very great, never exceeding ten or twelve degrees, b can never differ from 90° above a degree or two, and its sine cannot differ much from unity. Therefore X will be very nearly equal to $\frac{\text{CD}}{\text{sin. } a}$, which is also very nearly equal to $\frac{\text{CD}}{2\,\text{sin. } \frac{1}{2}\,a}$; because a is small, and the sines of small arches are nearly equal and proportional to the arches themselves. There is even a small compensation of errors in this formula. For as the sine of 90° is somewhat too large, which would give X too great, 2 sin. $\frac{1}{2}\,a$ is also larger than the sine of a. Thus let a be 12°: then the nearest multiple of a is 84° or 96°, both of which are as far removed as possible from 90°, and the error is as great as possible, and is nearly $\frac{1}{160}$th of the whole.

This approximation gives us a very simple construction. Let CM be the required length of the trumpet, and draw ML perpendicular to the axis in O. It is evident that sin. MCO : rad. $=$ MO : CM, and CM or $\text{X} = \frac{\text{MO}}{\text{sin.} \frac{1}{2}\,a} = \frac{\text{LM}}{2\,\text{sin.} \frac{1}{2}\,a}$; but $\text{X} = \frac{\text{CD}}{2\,\text{sin.} \frac{1}{2}\,a}$, and therefore LM equal to CD.

If therefore the cone be of such a length, that its diameter at the mouth is equal to the length of the part cut off, every line of sound will have at least as many reflections, save one, as if the cone were infinitely long; and the last reflected line will either be parallel to the opposite side of the cone, or lie nearer the axis than this parallel; consequently such a cone will confine all the reflected sounds within a cone whose angle is $2\,a$, and will augment the sound in the proportion of the spherical base of this cone to a complete hemispherical surface. Describe the circle DKT round C, and making DT an arch of 90°, draw the chord DT. Then, since the circles described with the radii DK, DT, are equal to the spherical surfaces generated by the revolution of the arches DK and DKT round the axis CD, the sound will be condensed in the proportion of DK^2 to DT^2.

This appears to be the best general rule for constructing the instrument; for, to procure another reflection, the tube must be prodigiously lengthened, and we cannot suppose that one reflection more will add greatly to its power.

It appears, too, that the length depends chiefly on the angle of the cone, for the mouth-piece may be considered as nearly a fixed quantity. It must be of a size to admit the mouth when speaking with force and without constraint. About an inch and a half may be fixed on for its diameter. When therefore we propose to confine the sound to a cone of twice the angle of the trumpet, the whole is determined by that angle. For since in this case LM is equal to CD, we have DK : CD = LM (or CD) : CM and $CM = \frac{CD^2}{DK}$.

$$\begin{array}{ll} \text{But} & 2\sin.\tfrac{1}{2}a : 1 = DK : CD, \\ \text{and} & 2\sin.\tfrac{1}{2}a : 1 = CD : CM; \\ \text{therefore} & 4\sin.^2\tfrac{1}{2}a : 1 = DK : CM, \end{array}$$

$$\text{And}\quad CM = \frac{DK}{4\sin.^2\frac{1}{2}a} = \frac{DK}{\sin.^2 a}$$ very nearly. And since DK is an inch and a half, we get the length in inches counted from the apex of the cone $= \frac{1\frac{1}{2}}{\sin.^2 a}$, or $\frac{3}{2\sin.^2 a}$. From this we must cut off the part CD, which is $= \frac{DK}{2\sin.\frac{1}{2}a}$, or very nearly $\frac{DK}{\sin. a}$, or $\frac{3}{2\sin. a}$, measured in inches, and we must make the mouth of the same width $\frac{3}{2\sin. a}$.

On the other hand, if the length of the trumpet is fixed on, we can determine the angle of the cone. For let the length (reckoned from C) be L; we have $2\sin.^2 a = \frac{3}{L}$, or $\sin.^2 a = \frac{3}{2L}$, and $\sin. a = \sqrt{\frac{3}{2L}}$.

Thus let six feet or 72 inches be chosen for the length of the cone, we have $\sin. a = \sqrt{\frac{3}{144}} = \sqrt{\frac{1}{48}} = 0{\cdot}14434 = \sin. 8° 17'$ for the angle of the cone; and the width at the mouth is $\frac{3}{2\sin. a} = 10{\cdot}4$ inches. This being taken from 72, leaves 61·6 inches for the length of the trumpet.

And since this trumpet confines the reflected sounds to a cone of 16° 34′, we have its magnifying power $= \frac{DT^2}{DK^2}$, $= \frac{(\frac{1}{2}DT)^2}{(\frac{1}{2}DK)^2} = \frac{\sin.^2 45°}{\sin.^2 4° 8'\frac{1}{2}} = 96$ nearly. It therefore condenses the sound about 96 times; and if the distribution were uniform, it would be heard $\sqrt{96}$, or nearly 10 times farther off; for the loudness of sounds is supposed to be inversely as the square of the distance from the centre of undulation.

But before we can pronounce with precision on the performance of a speaking trumpet, we must examine into the manner in which the reflected sounds are distributed over the space in which they are all confined.

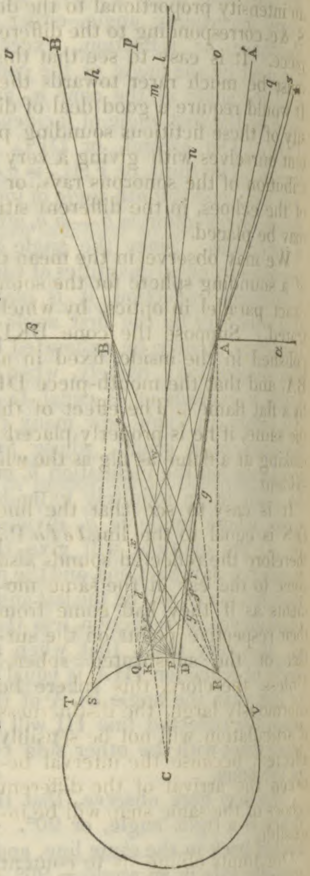
Let BKDA (fig. 3) be the section of a conical trumpet by a plane through the axis; let C be the vertex of the cone, and CW its axis; let TKV be the section of a sphere, having its centre in the vertex of the cone; and let P be a sonorous point on the surface of the sphere, and P *a f e l* the path of a line of sound lying in the plane of the section. In the great circle of the sphere take KQ = KP, DR = DQ, and KS = KR. Draw QB*h*; also draw Q*dn* parallel to DA; and draw PB, P*d*, PA.

1. Then it is evident that all the lines drawn from P, within the cone APB, proceed without reflection, and are diffused as if no trumpet had been used.

2. All the sonorous lines which fall from P on KB are reflected from it as if they had come from Q.

3. All the sonorous lines between BP and *d*P have suffered but one reflection; for *dn* will no more meet DAA′ so as to be reflected again.

Fig. 3.



4. All the lines which have been reflected from KB, and afterwards from DA, proceed as if they had come from R. For the lines reflected from KB proceed as if they had come from Q; and lines coming from Q and reflected by DA, proceed as if they had come from R. Therefore draw RA*o*, and also draw R*gm* parallel to KB, and draw Q*c*A*q*, Q*bg*, P*c*, and P*b*. Then,

5. All the lines between *b*P and *c*P have been twice reflected.

Again, draw SB*p*, B*r*R, *ruq*, S*x*A, R*yx*, Q*zy*.

6. All the lines between *u*P and *z*P have suffered three reflections.

Draw the tangents TA*t*, VB*v*, crossing the axis in W.

7. The whole sounds will be propagated within the cone *v*W*t*. For to every sonorous point in the line KD there corresponds a point similar to Q, regulating the first reflection from KB; and a point similar to R, regulating the second reflection from DA; and a point S regulating the third reflection from KB, &c. And similar points will be found regulating the first reflection from DA, the second from KB, and the third from DA, &c.; and lines drawn from all these through A and B must lie within the tangents TA and VB.

8. Thus the centres of reflection of all the sonorous lines which lie in planes passing through the axis, will be found in the surface of this sphere; and it may be considered as a sonorous sphere, whose sounds first concentrate in W, and are then diffused in the cone *v*W*t*.

It may be demonstrated nearly in the same manner, that the sonorous lines which proceed from P, but not in the plane passing through the axis, also proceed, after various reflections, as if they had come from points in the surface of the same sphere. The only difference in the demonstration is, that the centres Q, R, S of the successive reflections are not in one plane, but in a spiral line winding round the surface of the sphere according to fixed laws. The foregoing conclusions are therefore general for all the sounds which come in all directions from every point in the area of the mouth-piece.

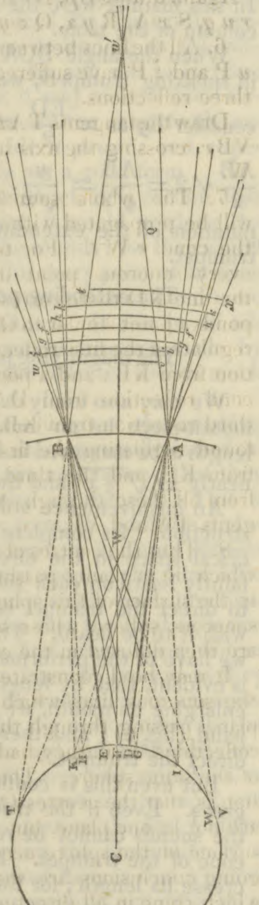
Thus it appears, that a conical trumpet is well fitted for increasing the force of sounds by diminishing their final divergence. For had the speaker's mouth been in the open air, the sounds which are now confined within the cone *v*W*t* would have been diffused over a hemisphere; and we so that prolonging the trumpet must confine the sounds still more, because this will make the angle BWA still smaller; a longer tube must also occasion more reflections, and consequently send more sonorous undulations to the ear at a distance placed within the cone v W t.

We have now obtained a very connected view of the whole effect of a conical trumpet. It is the same as if the whole segment TKDV were sounding, every part of it with an intensity proportional to the density of the points Q, R, S, &c. corresponding to the different points P of the mouth-piece. It is easy to see that this cannot be uniform, but must be much rarer towards the margin of the segment. It would require a good deal of discussion to show the density of these fictitious sounding points; and we shall content ourselves with giving a very palpable view of the distribution of the sonorous rays, or the density (so to speak) of the echoes, in the different situations in which a hearer may be placed.

We may observe, in the mean time, that this substitution of a sounding sphere for the sounding mouth-piece has an exact parallel in optics, by which it will be greatly illustrated. Suppose the cone BKDA (fig. 3) to be a tube polished in the inside, fixed in a wall B α, perforated in BA, and that the mouth-piece DK is occupied completely by a flat flame. The effect of this on a spectator will be the same, if he is properly placed in the axis, as if he were looking at a flame as big as the whole sphere. This is very evident.

It is easy to see that the line le is equal to the line $lefa$P; therefore the reflected sounds also come to the ear in the same moments as if they had come from their respective points on the surface of the substituted sphere. Unless, therefore, this sphere be enormously large, the distinctness of articulation will not be sensibly affected, because the interval between the arrival of the different echoes of the same snap will be insensible.

Fig. 4.



Our limits oblige us to content ourselves with exhibiting this evident similarity of the progress of echo from the surface of this phonic sphere, to the progress of light from the same luminous sphere shining through a hole of which the diameter is AB. The direct investigation of the intensity of the sound in different directions and distances would take up much room, and give no clearer conception of the subject. The intensity of the sound in any point is precisely similar to the intensity of the illumination of the same point; and this is proportional to the portion of the luminous surface seen from this point through the hole directly, and to the square of the distance inversely. The intelligent reader will acquire a distinct conception of this matter from fig. 4, which represents the distribution of the sonorous lines, and by consequence the degree of loudness which may be expected in the different situations of the hearer.

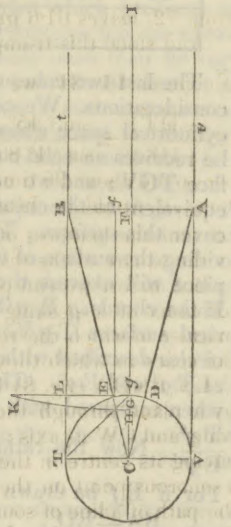
As we have already observed, the effect of the cone of the trumpet is perfectly analogous to the reflection of light from a polished concave conical mirror. Such an instrument would be equally fitted for illuminating a distant object. We imagine that these would be much more powerful than the spherical or even parabolic mirrors commonly used for this purpose. These last, having the candle in the focus, also send forward a cylinder of light of equal width with the mirror. But it is well known, that oblique reflections are prodigiously more vivid than those made at greater angles. Where the inclination of the reflected light to the plane of the mirror does not exceed eight or ten degrees, it reflects about three fourths of the light which falls on it. But when the inclination is 80°, it does not reflect one fourth part.

We may also observe, that the density of the reflected sounds by the conical trumpet ABC (fig. 4) is precisely similar to that of the illumination produced by a luminous sphere TDV shining through a hole AB. There will be a space circumscribed by the cone formed by the lines TBt and VAv, which is uniformly illuminated by the whole sphere (or rather by the segment TDV), and on each side there is a space illuminated by a part of it only, and the illumination gradually decreases towards the borders. A spectator placed much out of the axis, and looking through the hole AB, may not see the whole sphere. In like manner, he will not hear the whole sounding sphere: he may be so far from the axis as neither to see nor hear any part of it.

Assisting our imagination by this comparison, we perceive that beyond the point w' there is no place where *all* the reflected sounds are heard. Therefore, in order to preserve the magnifying power of the trumpet at any distance, it is necessary to make the mouth as wide as the sonorous sphere. Nay, even this would be an imperfect instrument, because its power would be confined to a very narrow space; and if it be not accurately pointed to the person listening, its power will be greatly diminished. And we may observe, by the way, that we derive from this circumstance a strong confirmation of the justness of Mr Lambert's principles; for the effects of speaking trumpets are really observed to be limited in the way here described. Parabolic trumpets have been made, and they fortify the sound not only in the cylindrical space in the direction of the axis, but also on each side of it; which should not have been the case, had their effect depended only on the undulations formed by the parabola in planes perpendicular to the axis. But to proceed.

Let BCA (fig. 5) be the cone, ED the mouth-piece, TEDV the equivalent sonorous sphere, and TBAV the circumscribed cylinder. Then CA or CB is the length of cone that is necessary for maintaining the magnifying power at all distances. We have two conditions to be fulfilled. The diameter ED of the mouth-piece must be of a certain fixed magnitude, and the diameter AB of the outer end must be equal to that of the equivalent sonorous sphere. These conditions determine all the dimensions of the trumpet and its magnifying power. And, first, with respect to the dimensions of the trumpet.

Fig. 5.



The similarity of the triangles ECG and BCF gives CG : ED = CF : AB; but CG = BF = $\frac{1}{2}$AB, and CF = CG + GF = GF + $\frac{1}{2}$AB; therefore $\frac{1}{2}$AB : ED = GF + $\frac{1}{2}$AB : AB, and AB : ED = 2 GF + AB : AB; therefore 2 GF × ED + AB × ED = AB^2, and 2 GF × ED = AB^2 — AB × ED = AB × (AB — ED) and GF

$= \frac{AB\times(AB-ED)}{2\,ED}$. And, on the other hand, because $AB^2 - AB\times ED = 2\,GF\times ED$, we have $AB^2 - AB\times ED + \frac{1}{4}ED^2 = 2\,GF\times ED + \frac{1}{4}ED^2$, or $(AB - \frac{1}{2}ED)^2 = 2\,GF\times ED + \frac{1}{4}ED^2$, and $AB = \sqrt{(2\,GF\times ED + \frac{1}{4}ED^2)} + \frac{1}{2}ED$.

Let x represent the length of the trumpet, y the diameter at the great end, and m the diameter of the mouth-piece. Then $x = \frac{y(y-m)}{2\,m}$, and $y = \sqrt{(2xm + \frac{1}{4}m^2)} + \frac{1}{2}m$. Thus the length and the great diameter may be had reciprocally. The useful case in practice is to find the diameter for a proposed length, which is obtained by the last equation.

Now if we take all the dimensions in inches, and fix m at an inch and a half, we have $2\,x\,m = 3\,x$, and $\frac{1}{4}m^2 = 0{\cdot}5625$, and $\frac{1}{2}m = 0{\cdot}75$; so that our equation becomes $y = \sqrt{(3\,x + 0{\cdot}5625)} + 0{\cdot}75$. The following table gives the dimensions of a sufficient variety of trumpets. The first column is the length of the trumpet in feet; the second column is the diameter of the mouth in inches; the third column is the number of times that it magnifies the sound; and the fourth column is the number of times that it increases the distance at which a man may be distinctly heard by its means; the fifth contains the angle of the cone.

GF Feet.	AB Inches.	Magnifying.	Extending.	ACB.
				° ′
1	6·8	42·6	6·5	24 53
2	9·3	77·8	8·8	18 23
3	11·2	112·4	10·6	15 18
4	12·8	146·6	12·1	13 24
5	14·2	180·4	13·4	12 04

11	20·7	380·9	19·5	8 18
12	21·5	414·6	20·4	7 58
15	24·	513·6	22·7	7 09
18	26·2	612·3	24·7	6 33
21	28·3	711·2	26·6	6 05
24	30·2	810·1	28·5	5 42
ED in all is = 1·5.				

The last two columns are constructed on the following considerations. We conceive the hearer placed within the cylindrical space whose diameter is BA. In this situation he receives an echo coming apparently from the whole surface TGV; and we account the effect of the trumpet as equivalent to the united voices of as many mouths as would cover this surface. Therefore the quotient obtained by dividing the surface of the hemisphere by that of the mouth-piece will express the magnifying power of the trumpet. If the chords g E, g T, be drawn, we know that the spherical surfaces T g V, E g D, are respectively equal to the circles described with the radii T g, E g, and are therefore as Tg^2 and Eg^2. Therefore the audibility of the trumpet, when compared with a single voice, may be expressed by $\frac{Tg^2}{Eg^2}$. Now the ratio of Tg^2 to Eg^2 is easily obtained. For if E f be drawn parallel to the axis, it is plain that $Bf = \frac{BA-ED}{2}$, and that E f is to B f as radius to the tangent of BCF; which angle we may call a. Therefore $\tan.\, a = \frac{y-m}{2\,x}$, and thus we obtain the angle a. But if the radius CE be accounted 1, T g is $= \sqrt{2}$, and E g is $= 2\sin.\frac{a}{2}$. Therefore $\frac{Tg}{Eg} = \frac{\sqrt{2}}{2\sin.\frac{a}{2}}$, and the magnifying power of the trumpet is $= \frac{2}{4\sin.^2\frac{a}{2}} = \frac{1}{2\sin.^2\frac{a}{2}}$. The numbers, therefore,, in the third column of the table are each $= \frac{1}{2\sin.^2\frac{a}{2}}$.

But the more usual way of conceiving the power of the trumpet is, by considering how much farther it will enable us to hear a voice equally well. Now we suppose that the audibility of sounds varies in the inverse duplicate ratio of the distance. Therefore if the distance d, at which a man may be distinctly heard, be increased to z, in the proportion of EG to T g, the sound will be less audible, in the proportion of Tg^2 to EG^2. Therefore the trumpet will be as well heard at the distance z as the simple voice is heard at the distance d. Therefore $\frac{z}{d}$ will express the *extending power* of the trumpet, which is therefore $= \frac{\sqrt{2}}{2\sin.\frac{a}{2}}$. In this manner were the numbers computed for the fourth column of the table.

When the angle BCA is small, which is always the case in speaking trumpets, we may, without any sensible error, consider E g as $= \frac{ED}{2} = \frac{m}{2}$. And $Tg = TC \times \sqrt{2} = \frac{AB}{2}\sqrt{2} = \frac{AB}{\sqrt{2}} = \frac{y}{\sqrt{2}}$. This gives a very easy computation of the extending and magnifying powers of the trumpet.

The extending power is $= \sqrt{2}\,\frac{y}{m}$.

The magnifying power is $= 2\,\frac{y^2}{m^2}$.

We may also easily deduce from the premises, that if the mouth-piece be an inch and a half in diameter, and the length x be measured in inches, the extending power is very nearly $= \sqrt{\frac{8}{3}x}$ and the magnifying power $= \frac{8}{3}x$.

An inconvenience still attends the trumpet of this construction. Its complete audibility is confined to the cylindrical space in the direction of the axis, and it is more faintly heard on each side of it. We are therefore obliged to direct the trumpet very exactly to the spot where we wish it to be heard. This is confirmed by all the accounts we have of the performance of great speaking trumpets. It is evident, that by lengthening the trumpet, and therefore enlarging its mouth, we make the lines TBt and VAv expand (fig. 4); and therefore it will not be so difficult to direct the trumpet.

But even this is confined within the limits of a few degrees. Even if the trumpet were continued without end, the sounds cannot be reinforced in a wider space than the cone of the trumpet. But it is always advantageous to increase its length; for this makes the extreme tangents embrace a greater portion of the sonorous sphere, and thus increase the sound in the space where it is all reflected. And the limiting tangents TB, VA, expand still more, and thus the space of full effect is increased. But either of these augmentations is very small in comparison of the augmentation of size. If the trumpet of fig. 5 were made an ndred times longer, its power would not be increased he half.

We need not therefore aim at much more than to proice a cylindrical space of full effect; and this will always done by the preceding rules, or table of constructions. 'e may give the trumpet a third or a fourth part more ngth, in order to spread a little the space of its full effect, d thereby make it more easily directed to the intended ject. But in doing this we must be careful to increase e diameter of the mouth as much as we increase the ngth; otherwise we produce the very opposite effect, and ke the trumpet greatly inferior to a shorter one, at all stances beyond a certain point. For by increasing the ngth while the part CG remains the same, we cause the ngents TB and VA to meet on some distant point, bend which the sound diffuses prodigiously. The construcn of a speaking trumpet is therefore a problem of some cety; and as the trials are always made at some considerle distance, it may frequently happen that a trumpet iich is not heard at a mile's distance, may be made very dible two miles off, by cutting off a piece at its wide end.

After this minute consideration of the conical trumpet, might proceed to consider those of other forms. In parular the hyperbolic, proposed by Cassegrain, and the rabolic, proposed by Hase, seem to merit consideration. it if we examine them merely as reflectors of echoes, we ll find them inferior to the conical.

With respect to the hyperbolic trumpet, its inaptitude evident at first sight; for it must dissipate the echoes ore than a conical trumpet. Indeed Mr Cassegrain proeds on quite different principles, depending on the meanism of the aerial undulations: his aim was to increase e agitation in each pulse, so that it may make a more forle impulse on the ear. But we are too imperfectly acainted with this subject to decide *a priori;* and expence shows that the hyperbola is not a good form.

With respect to the parabolic trumpet, it is certain that the mouth-piece were but a point, it would produce the ost favourable reflection of all the sounds; for they would proceed parallel to the axis. But every point of an open outh must be considered as a centre of sound, and none it must be kept out of the trumpet. If this be all adtted, it will be found that a conical trumpet, made by e preceding rules, will dissipate the reflected sounds much s than the parabolic.

Those who have endeavoured to improve the speaking impet on mechanical principles, have generally aimed at creasing the violence of the elastic undulations, that they ay make a more forcible impulse on the ear. This is e object in view in the parabolic trumpet. All the unduions are converted into others which are in planes perpencular to the axis of the instrument; so that the same little ass of air is agitated again and again in the same direction. om this it is obvious to conclude, that the total agitation ll be more violent. But, in the first place, these violent itations must diffuse themselves laterally as soon as they t out of the trumpet, and thus be weakened, in a proporon that is perhaps impossible for the most expert analyst determine. But, moreover, we are not sufficiently acainted with the mechanism of the very first agitations, to able to perceive what conformation of the trumpet will use the reflected undulations to increase the first undulaons, or to check them. For during the production of a ntinued sound in a trumpet, it must happen that a parcel air, which is in a state of progressive agitation as it akes a pulse of one sound, may be in a state of retrograde itation as it is part of a pulse of air producing another und. We cannot (at least no mathematician has yet done) discriminate, and then combine these agitations, with the telligence and precision that are necessary for enabling to say what is the ultimate accumulated effect. Mr Lambert, therefore, did wisely in abstaining from this intricate investigation; and we are highly obliged to him for deducing such a body of demonstrable doctrine from the acknowledged, but ill understood, fact of the reflection of echoes.

We know that two sounds actually cross each other without any mutual disturbance; for we can hear either of them distinctly, provided the other is not so loud as to stun our ears, in the same manner as the glare of the sun dazzles our eyes. We may therefore depend on all the consequences which are legitimately deduced from this fact, in the same manner as we depend on the science of catoptrics, which is all deduced from a fact perfectly similar, and as little understood.

But the preceding propositions by no means explain or comprehend all the reinforcement of sound which is really obtained by means of a speaking trumpet. In the first place, although we cannot tell in what degree the aerial undulations are increased, we cannot doubt that the reflections which are made in directions which do not greatly deviate from the axis, do really increase the agitation of the particles of air. We see a thing perfectly similar to this in the waves on water. Take a long slip of lead, about two inches broad, and having bent it into the form of a parabola, set it into a large flat trough, in which the water is about an inch deep. Let a quick succession of small drops of water fall precisely on the focus of the parabola. We shall see the circular waves, proceeding from the focus, all converted into waves perpendicular to the axis; and we shall frequently see these straight waves considerably augmented in their height and force. We say generally, for we have sometimes observed that these reflected waves were not sensibly stronger than the circular or original waves. We do not exactly know to what this difference must be ascribed; we are disposed to attribute it to the frequency of the drops. This may be such, that the interval of time between each drop is precisely equal, or at least commensurable, to the time in which the waves run over their own breadth. This is a pretty experiment; and the ingenious mechanician may make others of the same kind which will greatly illustrate several difficult points in the science of sounds. We may conclude, in general, that the reflection of sounds, in a trumpet of the usual shapes, is accompanied by a real increase of the aerial agitations; and in some particular cases we find the sounds prodigiously increased. Thus, when we blow through a musical trumpet, and allow the air to take that uniform undulation which can be best maintained in it, namely, that which produces its musical tone, where the whole tube contains but one or two undulations, the agitation of a particle must then be very great; and it must describe a very considerable line in its oscillations. When we suit our blast in such a manner as to continue this note, that is, this undulation, we are certain that the subsequent agitations conspire with the preceding agitation, and augment it. And accordingly we find that the sound is increased to a prodigious degree. A cor de chasse, or a bugle horn, when properly winded, will almost deafen the ear; and yet the exertion is a mere nothing in comparison with what we make when bellowing with all our force, but with not the tenth part of the noise. We also know, that if we speak through a speaking trumpet in the key which corresponds with its dimensions, it is much more audible than when we speak in a different pitch. These observations show, that the loudness of a speaking trumpet arises from something more than the sole reflection of echoes considered by Mr Lambert. The very echoes are rendered louder.

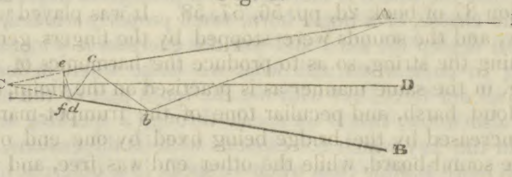
In the next place, the sounds are increased by the vibrations of the trumpet itself. The elastic matter of the trumpet is thrown into tremors by the undulations which proceed from the mouth-piece. These tremors produce pulses in the contiguous air, both in the inside of the trumpet and on that which surrounds it. These undulations within the trumpet produce original sounds, which are added to the reflected sounds; for the tremor continues for some little time, perhaps the time of three, or four, or more pulses. This must increase the loudness of the subsequent pulses; we cannot say to what degree, because we do not know the force of the tremor which the part of the trumpet requires; but we know that these sounds will not be magnified by the trumpet to the same degree as if they had come from the mouth-piece; for they are reflected as if they had come from the surface of a sphere which passes through the agitated point of the trumpet. In short, they are magnified only by that part of the trumpet which lies without them. The whole sounds of this kind, therefore, proceed as if they came from a number of concentric spherical surfaces, or from a solid sphere whose diameter is twice the length of the trumpet cone.

All these agitations arising from the tremors of the trumpet tend greatly to hurt the distinctness of articulation; because, coming from different points of a large sphere, they arrive at the ear in a sensible succession, and thus change a momentary articulation to a lengthened sound, and give the appearance of a number of voices uttering the same words in succession. It is in this way that, when we clap our hands together near a long rail, we raise an echo from each post, which produces a chirping sound of some continuance. For these reasons it is found advantageous to check all tremors of the trumpet by wrapping it up in woollen lists. This is also necessary in the musical trumpet. With respect to the undulations produced by the tremors of the trumpet in the air contiguous to its outside, they also hurt the articulation. At any rate, this is so much of the sonorous momentum uselessly employed, because they are diffused like common sounds, and receive no augmentation from the trumpet.

Hearing trumpet. It is evident that this instrument may be used for aiding the hearing; for the sonorous lines are reflected in either direction. We know that all tapering cavities greatly increase external noises; and we observe the brutes prick up their ears when they want to hear uncertain or faint sounds. They turn them in such directions as are best suited for the reflection of the sound from the quarter whence the animal imagines that it comes. Let us apply Mr Lambert's principle to this very interesting case, and examine whether it be possible to assist dull hearing in like manner as the optician has assisted imperfect sight. The subject is greatly simplified by the circumstances of the case; for the sounds to which we listen generally come in nearly one direction, and all that we have to do is to produce a constipation of them. And we may conclude, that the audibility will be proportional to this constipation.

Therefore let ABC, fig. 6, be the cone, and CD its axis.

Fig. 6.



The sound may be conceived as coming in the direction RA, parallel to the axis, and to be reflected in the points A, *b*, *c*, *d*, *e*, till the angle of incidence increases to 90°; after which the subsequent reflections send the sound out again. We must therefore cut off a part of the cone; and, because the lines increase their angle of incidence at each reflection, it will be proper to make the angle of the cone an aliquot part of 90°, that the least incidence may amount precisely to that quantity. What part of the cone should be cut off, may be determined by the former principles. Call the angle ACD, a. We have $\mathrm{C}e = \frac{\mathrm{CA} \cdot \sin. a}{\sin. (2n + 1)a}$, when the sound gets the last useful reflection. Then we have the diameter of the mouth $\mathrm{AB} = 2\,\mathrm{CA} \cdot \sin. a$, and that of the other end $ef = \mathrm{C}e \cdot 2 \sin. a$. Therefore the sounds will be constipated in the ratio of CA^2 to $\mathrm{C}e^2$, and the trumpet will bring the speaker nearer in the ratio of CA to C*e*.

When the lines of reflected sound are thus brought together, they may be received into a small pipe perfectly cylindrical, which may be inserted into the external ear. This will not change their angles of inclination to the axis, nor their density. It may be convenient to make the internal diameter of this pipe $\frac{1}{3}$d of an inch. Therefore $\mathrm{C}e \cdot \sin. a$ is $= \frac{1}{6}$th of an inch. This circumstance, in conjunction with the magnifying power proposed, determines the other dimensions of the hearing trumpet. For $\mathrm{C}e = \frac{1}{6 \sin. a} = \frac{\mathrm{CA} \sin. a}{\sin. (2n + 1)a}$, and $\mathrm{CA} = \frac{\sin. (2n + 1\,a)}{6 \sin.^2 a}$.

Thus the relation of the angle of the cone and the length of the instrument is ascertained, and the sound is brought nearer in the ratio of CA to C*e*, or of $\sin. (2n + 1)\,a$ to $\sin. a$. And seeing that we found it proper to make $(2n + 1)\,a = 90°$, we obtain this very simple analogy, $1 : \sin. a = \mathrm{CA} : \mathrm{C}e$. And the sine of $\frac{1}{2}$ the angle of the cone is to radius as 1 to the approximating power of the instrument.

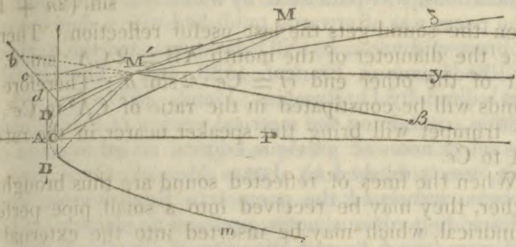
Thus let it be required that the sound may be as audible as if the voice were 12 times nearer. This gives $\frac{\mathrm{CA}}{\mathrm{C}e} = 12$; and $\sin. a = \frac{1}{12}$, and $a = 4° \; 47'$, and the angle of the cone $= 9° \; 34'$. Then $\mathrm{CA} = \frac{1}{6 \sin.^2 a} = \frac{1}{6 \times \frac{1}{144}} = \frac{144}{6} = 24$. Therefore the length of the cone is 24 inches. From this take $\mathrm{C}e = \frac{\mathrm{CA}}{12} = 2$, and the length of the trumpet is 22 inches. The diameter at the mouth is $2\,\mathrm{C}e = 4$ inches. With this instrument one voice should be as loud as 144.

If it were required to approximate the sound only four times, making it 16 times stronger than the natural voice at the same distance, the angle ACB must be 29°, A*e* must be 2 inches, AB must be $1\frac{1}{3}$d inch, and *ef* must be $\frac{1}{3}$d of an inch.

It is easy to see that when the size of the ear-end is the same in all, the diameters at the outer end are proportional to the approximating powers, and the lengths of the cones are proportional to the magnifying powers.

We shall find the parabolic conoid the preferable shape for an acoustic trumpet; because, as the sounds come into the instrument in a direction parallel to the axis, they are reflected so as to pass through the focus. The parabolic conoid must therefore be cut off through the focus, that the sounds may not go out again by the subsequent reflections; and they must be received into a cylindrical pipe of one third of an inch in diameter. Therefore the parameter of this parabola is one sixth of an inch, and the focus is one twelfth of an inch from the vertex. This determines the whole instrument; for they are all portions of one parabolic conoid. Suppose that the instrument is required to approximate the sound 12 times, as in the example of the conical instrument. The ordinate at the mouth must be 12 times the 6th of an inch, or 2 inches; and the mouth diameter is four inches, as in the conical instrument. Then, For the length, observe that DC in fig. 7 is $\frac{1}{6}$th of an inch,

Fig. 7.



and MP is 2 inches, and AC is $\frac{1}{12}$th of an inch, and $DC^2 : MP^2 = AC : AP$. This will give AP = 12 inches, and $CP = 11\frac{1}{12}$ths; whereas in the conical tube it was 22. In like manner, an instrument which approximates the sounds four times, is only $1\frac{1}{4}$th inch long, and $1\frac{1}{4}$th inch diameter at the larger end. Such small instruments may be very exactly made in the parabolic form, and are certainly preferable to the conical. But since even these are of a very moderate size when intended to approximate the sound only a few times, and as they can be accurately made by any tinman, they may be of more general use. One of 12 inches long, and 3 inches wide at the larger end, should approximate the sound at least 9 times.

A general rule for making them.—Let *m* express the approximating power intended for the instrument. The length of the instrument in inches is $\frac{m\,(m-1)}{6}$, and the diameter at the mouth is $\frac{m}{3}$. The diameter at the small end is always one third of an inch.

In trumpets for assisting the hearing, all reverberation of the trumpet must be avoided. It must be made thick, of the least elastic materials, and covered with cloth externally. For all reverberation lasts for a short time, and produces new sounds, which mix with those that are coming in. We must also observe, that no acoustic trumpet can separate those sounds to which we listen from others that are made in the same direction. All are received by it, and magnified in the same proportion. This is frequently a very great inconvenience.

There is also another imperfection, which we imagine cannot be removed, namely, an odd confusion, which cannot be called indistinctness, but a feeling as if we were in the midst of an echoing room. The cause seems to be this: Hearing gives us some perception of the direction of the sounding object, not indeed very precise, but sufficiently so for most purposes. In all instruments which we have described for constipating sounds, the last reflections are made in directions very much inclined to the axis, and inclined in many different degrees. Therefore they have the appearance of coming from different quarters, and instead of the perception of a single speaker, we have that of a sounding surface of great extent. We do not know any method of preventing this, and at the same time increasing the sound.

There is an observation which it is of importance to make on this theory of acoustic instruments. Their performance does not seem to correspond to the computations founded on the theory. When they are tried, we cannot think that they magnify so much. Indeed it is not easy to find a measure by which we can estimate the degree of audibility. When a man speaks to us at the distance of a yard, and then at the distance of two yards, we can hardly think that there is any difference in the loudness; though theory says that it is four times less in the last of the two experiments; and we cannot but adhere to the theory in this very simple case, and must attribute the difference to the impossibility of measuring the loudness of sounds with precision. And because we are familiarly acquainted with the sound, we can no more think it four times less at twice the distance, than we can think the visible appearance of a man four times less when he is at a quadruple distance. Yet we can completely convince ourselves of this, by observing that he covers the appearance of four men at that distance. We cannot easily make the same experiment with voices.

But, besides this, we have compared two hearing trumpets, one of which should have made a sound as audible at the distance of 40 feet as the other did at 10 feet distance; but we thought them equal at the distance of 40 and 18. The result was the same in many trials made by different persons, and in different circumstances. This leads us to suspect some mistake in Mr Lambert's principle of calculation; and we think him mistaken in the manner of estimating the intensity of the reflected sounds. He conceives the proportion of intensity of the simple voice and of the trumpet to be the same with that of the surface of the mouth-piece to the surface of the sonorous hemisphere, which he has so ingeniously substituted for the trumpet. But this seems to suppose that the whole surface, generated by the revolution of the quadrantal arch TEG round the axis CG (fig. 4), is equally sonorous. We are assured that it is not; for even if we should suppose that each of the points Q, R, and S (fig. 3), are equally sonorous with the point P, these points of reflection do not stand so dense on the surface of the sphere as on the surface of the mouth-piece. Suppose them arranged at equal distances all over the mouth-piece, they will be at equal distances also on the sphere, only in the direction of the arches of great circles which pass through the centre of the mouth-piece. But in the direction perpendicular to this, in the circumference of small circles, having the centre of the mouth-piece for their pole, they must be rarer in the proportion of the sine of their distance from this pole. This is certainly the case with respect to all such sounds as have been reflected in the planes which pass through the axis of the trumpet; and we do not see (for we have not examined this point) that any compensation is made by the reflection which is not in planes passing through the axis. We therefore imagine that the trumpet does not increase the sound in the proportion of gE^2 to gT^2 (fig. 5), but in that of $\frac{gE^2}{GE}$ to $\frac{gT^2}{CT}$.

Mr Lambert seems aware of some error in his calculation, and proposes another, which leads nearly to this conclusion, but is founded on a principle which we do not think in the least applicable to the case of sounds. (B. B. B.)

Truncheon.

Trumpet, *Marine*, an old musical stringed instrument, said to derive its name from its inventor Marino or Marigni. Mersenne describes it as a monochord and as a dichord. See his Harmonicorum libri xii. Paris, 1652, proposition 37 of book 2d, pp. 56, 57, 58. It was played with a bow, and the sounds were stopped by the fingers gently touching the string, so as to produce the harmonics of the string, in the same manner as is practised on the violin, &c. The loud, harsh, and peculiar tone of the trumpet-marine was increased by the bridge being fixed by one end only to the sound-board, while the other end was free, and allowed to strike against the sound-board, according to the vibration of the string, &c. The sounds above the fundamental of the open string, followed those of the aliquots mentioned in article Music. The reader may consult an ingenious paper upon the marine trumpet in the fourth volume of the late Professor Robison's Mechanical Philosophy, edited by Dr Brewster in 1822, pp. 486–500.

TRUNCHEON, a short staff or baton used by kings, generals, and great officers, as a mark of their command.

TRUNDLE, a sort of carriage with low wheels, for drawing heavy and cumbersome burdens.

TRUNK, among botanists, that part of the herb which arises immediately from the root, and is terminated by fructification; the leaves, buds, and auxiliary parts of the herb not entering into its description. See VEGETABLE PHYSIOLOGY.

TRUNNIONS, or TRUNIONS, of a piece of ordnance, are those knobs or bunches of metal which bear it up on the cheeks of the carriage.

TRURO, a town in the hundred of Powder and county of Cornwall. It stands at the confluence of two rivers, the Kenwyn and the Allen, which surround the place, and below it unites with an estuary which is a part of the harbour of Falmouth, so that at spring tides it is navigable for vessels of 200 tons burden. In this way the chief products of the tin-mines are conveyed to the requisite markets for consumption. The town is well built, and some recent additions have been made, which have increased its beauty. The church is a spacious building, and is a good specimen of the architecture of the age in which it was erected, that of the reign of Henry VIII. The town-hall, besides its peculiar purpose, is used for holding the quarter-sessions for the county. There is a building called the Coinage Hall, where the process of coining the tin is carried on, and where the parliaments of the lord warden of the stanneries and the courts of the vice-warden are held, for the adjudication of whatever relates to the trade in tin, the chief object of pursuit in this place. Truro is an incorporated town, and by the recent law is divided into two wards, having a mayor, six aldermen, and seventeen councillors. It returns two members to the House of Commons. It has an endowed grammar-school, with exhibitions at Oxford. There are two weekly markets, one on Wednesday, the other on Friday. The population amounted in 1821 to 2719, and in 1831 to 2925.

TRUSS, a bundle or certain quantity of hay, straw, &c. A truss of hay contains fifty-six pounds, or half a hundred weight. Thirty-six trusses make a load.

TRUTH, a term used in opposition to falsehood, and applied to propositions which answer or accord to the nature and reality of the thing of which something is affirmed or denied.

TRYPHIODORUS, a poet of some note in the declining ages of Greek literature, was a native of Egypt, but the rest of his history is very obscurely known. "All that can be determined in relation to our author's age," says Merrick, "is that he lived between the reigns of [Alexander] Severus and Anastasius, the former of whom died at the beginning of the third century, and the latter at the beginning of the sixth." His writings were numerous, and several of them are mentioned by Suidas. One of these is described as *Marathoniaca*; a poem, which apparently related to the victory at Marathon. Another of his poems was founded on the story of Hippodamia; and a third, which is more frequently mentioned, was a lipogrammatic, or letter-dropping, Odyssey. "It is generally believed," as Merrick states, "that the poem was divided into as many books as there are letters in the Greek alphabet, and that in the first book there was no word which had an alpha in it; in the same manner he is thought to have proceeded through the whole work, leaving out in each book that letter by which the number of it was distinguished." The fantastic plan of this poem is well known to the English reader, from one of Addison's papers on false wit, Spectator, No. 59. All the works of Tryphiodorus have however perished, with the exception of his poem on the destruction of Troy, Ἰλίου Ἅλωσις, which consists of 681 hexameter verses.

The first edition of this poem was printed by Aldus, in an octavo volume which has no date, and which likewise includes the two poems of Quintus Calaber and Coluthus. That of Tryphiodorus was reprinted in several collections, and not unfrequently in a separate form. An edition, accompanied with a translation into Latin verse, and some annotations, was published by Jamotius, Lutet. 1557, 8vo. The poem was afterwards published with a double version, in prose and verse, by N. Frischlinus, and the castigations of Rhodomannus, Francof. 1588, 4to. The Greek text was edited by H. Rumpius, Hamb. 1617, 8vo. A good edition, containing the metrical version of Frischlinus, and the select notes of previous editors, added to some of his own, was published by James Merrick, Oxon. 8vo. He likewise translated the poem into English verse, and besides adding copious notes, prefixed an elaborate "Dissertation on the Life and Writings of Tryphiodorus." The *imprimatur* of his version is dated in 1739, that of the Greek and Latin edition in 1741; but no date appears in either of the title-pages. The Greek text, with a Latin version, Salvini's translation into Italian verse, and select annotations, was edited by Bandini, Florent. 1765, 8vo. Another edition of Tryphiodorus was accompanied with a poetical translation into Italian verse by A. T. di Villa, Modena, 1774, 8vo. Two editions, with various illustrations, were published by Thomas Northmore, Lond. 1791, 8vo, Lond. 1804, 8vo. A splendid edition, including a few emendations and critical notes, was more recently superintended by Schäfer, Lipsiæ, 1808, fol.

TSCHERIKOW'S ISLAND, an island in the North Pacific Ocean, observed by Vancouver in 1794, and so called after the companion of Behring's discoveries. Long. of the centre, 205. 4. E. Lat. 55. 49. N.

TSCHERNIGOW, a province or government of European Russia, which extends in north latitude from 52° 22′ to 53° 17′, and in east longitude from 30° 13′ to 34° 43′, and comprehends 25,564 square miles. It is an undulating district, with no lofty hills. The soil is of moderate fertility, producing rye, barley, and oats, and a small quantity of inferior wheat. The crops of hemp and flax afford the chief employment. The heavy products are sent by water to Odessa; and many cattle are bred, and sent to Germany for sale. The population amounts to 1,378,000 persons, all professing the Greek religion. The province is divided into twelve circles, which contain very few large towns for their extent.

TSCHERNIGOW, the capital city of the province of that name, as well as of the circle in which it stands. It is 773 miles from St Petersburg. It is situated on the banks of the river Desna, is defended by a fortress on a hill; and is the seat of an archbishop, who has a cathedral with a magnificent cupola. It contains about 2000 houses, with 10,000 inhabitants, who make some linen goods. Long. 31. 13. E. Lat. 51. 27. 10. N.

TSIOMPA, a country of Eastern Asia, between Cambodia and Cochin China, and now subjected to the latter kingdom. The country properly called Tsiompa is barren, intensely hot, and very unhealthy during a great part of the year. It however produces a little cotton, indigo, and silk, though of inferior quality. The inhabitants are tall, strongly made, of a reddish complexion, with the nose somewhat flattened.

TSONG-MING, an island near the coast of China, in the Eastern Seas, near the mouth of the Yang-tse-kiang river, about fifty miles in length and fifteen in breadth. The land is level, the air temperate and healthy, and the country in general pleasant. The land is well cultivated, except towards the north, where reeds grow naturally, and produce a considerable revenue, as they are used for building houses, and also for fuel, which is exported to the neighbouring islands. The country is divided by an infinite number of canals, which have high banks to guard against inundations. That portion of the island which is cultivated extends to the sea on the south side, and produces two crops every year, one of grain, and another of rice or cotton. Wheat, barley, and other grains, are also produced. Another description of land, though it appears barren, abounds in salt, which is an article of export. Long. 12. 54. E. Lat. 31. 38. N.

TUAK, a small island in the Red Sea, about two miles from the coast of Arabia. Long. 41. 58. E. Lat. 5. 58. N.

TUAM, a handsome town in the county of Galway, Ireland. It is situate on a rivulet, in a low but healthy situation, and is laid out on a regular plan; the market-house occupying the centre, from which four broad streets diverge. Of late, several useful improvements have been made, in widening the streets, erecting schools and other public institutions; but in the smaller streets and outlets, squalid poverty prevails to a great extent. Tuam boasts of very high antiquity in its ecclesiastical history; but no remains of its religious institutions now attest its former magnificence. It still however retains its importance, being now the seat of the bishop of Tuam, as well as of the titular archbishop of the same see. The cathedral is an ancient but small edifice; while that of the Roman Catholics is by far the finest of the modern buildings belonging to that body in Ireland. Here is also a handsome educational edifice belonging to the Catholics, called St Jarlath's College. There is a barrack for soldiers, and various other public buildings. Tuam has very much improved within these few years; it carries on a considerable retail trade, and a great deal of agricultural produce is sold at the weekly market. It possesses an extensive brewery, several tanneries and flour-mills, and the manufacture of linen and coarse canvass is carried on very successfully. There are several free schools, at which some hundreds of children are yearly instructed. Tuam is situated on the great thoroughfare, and is distant from Dublin 126 miles. The corporation consists, by the charter of James I., of a sovereign and twelve free burgesses. The population in 1821 amounted to 4571, and in 1831 to 6883.

TUBA, a small river of Asiatic Russia, which falls into the Yenisei, in the government of Kolyvan, sixteen miles south-west of Abakansk.

TUBERCLES, among physicians, denote little tumours which suppurate and discharge pus, and are often found in the lungs, especially of consumptive persons.

TÜBINGEN, a city of the kingdom of Wirtemberg, in the circle of the Black Forest, the capital of a surrounding bailiwick of the same name. It stands at the junction of the river Ammer with the Neckar, and is enclosed by walls and ditches, and has a castle, called the Pfalz, which contains many antiquities and curiosities. There are four churches, 880 houses, and, in 1830, 7220 inhabitants, some of whom are employed in making hosiery goods. Tübingen is chiefly an object of interest on account of its university, which has long been celebrated for the number of eminent scholars that it has produced. Many of the professors in the other German universities have been students at Tübingen. The branches of study pursued are, theology both Catholic and Protestant, jurisprudence, medicine in all its branches, philology, philosophy, and agriculture. There are two hospitals, an anatomical theatre, an observatory, a veterinary school, a chemical claboratory, and several collections of natural history, with a library of more than 30,000 volumes, besides valuable manuscripts. The students amounted in 1831 to 887. They board among the inhabitants at very cheap rates. Long. 8. 58. 16. E. Lat. 48. 31. 9. N.

TUCOPIA, an island in the Pacific Ocean, discovered by Quiros in 1606. Long. 167. E. Lat. 12. S.

TUCUMAN, a province of Paraguay, in South America, bounded on the north by the provinces of Los Chicas and Choco, on the east by Choco and Rio de la Plata, on the south by the country of Chicuitos and Pampas, and on the west by Chili. It now forms part of the republic of Buenos Ayres. See Buenos Ayres.

TUDELA, a town of Spain, in the province of Navarre. It stands on the river Ebro, near its reception of the waters of the Queiles. It has a magnificent bridge of seventeen arches across the Ebro, and is surrounded with a country highly fertile, and which yields abundance of wine, oil, wheat, hemp, and all kinds of garden-fruits and vegetables. It contains an old castle, ten parish churches, eight monasteries, 1500 houses, and 7295 inhabitants.

TUDURA, a village of Southern India, on the west bank of the Tunga river. It has in its vicinity a forest of fine timber. Long. 75. 25. E. Lat. 13. 40. N.

TULA, a province of European Russia, extending in east longitude from 35° 49′ to 38° 45′ and in north latitude from 52° 53′ to 54° 56′, and comprehending 11,997 square miles. It is generally a level district, with a few undulations; there are no lofty hills, very few forests, and no large lakes. It is chiefly drained by the river which comes from the province of Kaluga, and enters that of Moscow, and sometimes by overflowing inundates a great extent of land. The climate is healthy, and much milder than that of the adjoining province of Moscow. It is chiefly an agricultural country, yielding abundance of corn, but the growth of rye very far exceeds that of wheat. Of each description of grain there is a yearly surplus for exportation. The population amounts to 1,393,700 persons, all of the Greek church, except a few Germans established in or near the cities. The province is divided into twelve circles.

Tula, a city of Russia, the capital of a circle and of a province of its name. It is 606 miles from St Petersburg, and stands at the junction of the river Upa with the Tuliza. It is in part surrounded with a wall, is very antique, with crooked and narrow streets, and houses chiefly built of wood. It is the seat of a Greek bishop, whose diocese comprehends the whole province, as well as that of Kaluga. It has twenty-eight churches, a seminary for ecclesiastical education, a public college for the education of nobles, about 4000 houses, and 38,000 inhabitants. Among its establishments of manufactories, the most prominent is that of the emperor for the fabrication of arms of every description, which employs near 500 workmen, and provides arms and equipments for more than 15,000 men yearly. Long. 33. 56. 14. E. Lat. 54. 14. 40. N.

TULGOM, or Tulgong, a small town in Aurungabad, in the territories of the Mahratta peshwa. This place is noted as the scene of the defeat of the Bombay army in 1778, and its subsequent retreat. In 1806 the town and neighbourhood was almost depopulated by a famine.

TULL, Jethro, an Oxfordshire gentleman who farmed his own land, and introduced a new method of culture, to raise repeated crops of wheat from the same land without the necessity of manure; the principles of which he published in a Treatise on Horse-hoeing Husbandry.

TULLE, an arrondissement of the department of the Corrèze, in France, which extends over 999¼ square miles, and is divided into twelve cantons and 117 communes, with 129,799 inhabitants in 1836. The capital is the city of the same name, situated at the junction of the river Solane with the Corrèze. It is also the capital of the department. It was once more celebrated for its manufactures than it is at present; but some woollens are still made, and some thread lace. Close to the city is an establishment for making muskets and other arms. In 1836, the town and suburbs contained 9700 inhabitants. Long. 1. 37. E. Lat. 45. 16. N.

TULWUNDY, a town of Hindustan, province of Lahore. It is celebrated as the birth-place of Baba Nanoe Shah, the founder of the religion of the Sikhs. Long. 75. E. Lat. 31. 15. N.

TUMBELAN Islands, a cluster of small islands in the Eastern Seas. Long. 107. 58. E. Lat. 1. N.

TUMBRELL, Tumbrellum, or *Turbichetum*, is an engine of punishment, formerly employed for the correction of scolds and unquiet women.

TUMCURU, a town of Southern India, in the province of Mysore, defended by a good fort. It contains from 500 to 600 houses. Long. 77. 12. E. Lat. 13. 15. N.

TUMENE, a district of Tobolsk, in Asiatic Russia, with a capital of the same name, situated on the southern bank of the Tura, at its confluence with the Tumenka. It was built in 1586, on the site of a Tartar town, of which the traces still remain. It has a suburb, inhabited by Tartars and Bucharians. It contains 800 houses, with nine churches, a convent, and a nunnery. It has a foundery of bells, manufactories of soap, and considerable tanneries. Long. 100. 14. E. Lat. 57. N.

TUMLOOK, a small town of Bengal, in the district of Hooghly. The lands in the neighbourhood are extremely low, and only protected from inundation by embankments. It is the head-quarters of an agency for the manufacture of salt, which is a government monopoly. It is thirty-five miles south-west from Calcutta. Long. 88. 2. E. Lat. 22. 17. N.

TUN, a large vessel or cask, of an oblong form, largest in the middle, and diminishing towards its two ends, girt about with hoops, and used for stowing several kinds of merchandise for convenience of carriage; as brandy, oil, sugar, skins, &c.

Tun is also the name of a measure. A tun of wine is four hogsheads; of timber, a square of forty solid feet; and of coals, twenty hundredweight.

TUNBRIDGE, a town of the hundred of the same name, in the lathe of Aylesford, and county of Kent, thirty-one miles from London. It stands on a branch of the Medway, called the Tun, which is navigable, and by which coals and other goods are conveyed from the Thames. It is a well-built and clean town, with a handsome church, of modern construction. There is a well-endowed grammar school, which has many exhibitions at Oxford and Cambridge. The ruins still exist of that ancient castle, which has been the scene of many events in our national history. There is a well-supplied market on Friday. The inhabitants amounted in 1821 to 7406, and in 1831 to 10,380.

Tunbridge Wells, a town partly within the parish of Speldhurst, in the hundred of Washington and lathe of Aylesford, but the larger portion in Tunbridge. It is thirty-six miles from London, and six from the town of Tunbridge. It has been long celebrated for its mineral springs, which are strongly impregnated with iron. It consists of four divisions, viz. Mount Ephraim, Mount Pleasant, Mount Sion, and the Wells. The three former are composed of good houses, let as temporary residences, and the latter consists of rows of houses of smaller dimensions and expense. The place is much frequented in the summer, as well for the water as for the purity of the air. In the town are manufactures of wood, commonly called Tunbridge ware. The inhabitants of Speldhurst amounted in 1821 to 2297, and in 1831 to 2640, but the greater part of the new buildings are within the parish of Tunbridge.

TUNE, in *Music*, means either a short and popular melody, or correct intonation in singing or playing. See Music, Organ, Song, Temperament, Tonality.

TUNGUSES, a wandering native race of Asiatic Russia, who occupy the whole south-eastern portion of that vast territory, being first found on the banks of the Yenisei, and extending all the way eastward to the sea of Okhotsk. They resemble the Mongols in their countenance, though it is larger and still more flattened. They have small eyes, and a smiling physiognomy, and long black hair, which they allow freely to hang over their shoulders. They gain their subsistence, like all the other savages, by hunting and fishing, ranging through the woods and along the rivers, without any permanent abodes. They are extremely active and brave in their occupation, attacking with bows and arrows, their principal weapons, the fiercest animals, even bears; and the delicacy and quickness of sight by which they trace the game is almost incredible. The light mark which its steps leave on the moss or on the grass is a sufficient indication. The sable is the most valuable of the animals which they pursue. They clothe themselves rudely with the skins of rein-deer and wild sheep, having the hair or wool turned inward during the winter; in summer they wear the same skins tanned. They ornament this simple costume with beads and glass. They are praised as honest, brave, and frank, holding lying in detestation, and theft and fraud being unknown among them. The females are in general chaste, though a custom prevails among some of the nomadic tribes of lending their wives to strangers. On the women devolve all the domestic duties. To a certain age they are handsome, but after they grow old they are hideous. According to the last enumeration, the Tunguses in the government of Irkoutsk amounted to 13,264 males and 11,000 females; but from their wandering mode of life, this census is supposed to be imperfect. In the government of Tobolsk, the reported number amounted to 19,193.

TUNGUSKA, the name of three large rivers of Asiatic Russia, the tributaries of the Yenisei. The Lower Tunguska, the most northerly of the three, has the longest course. It takes its rise in the northern part of the government of Irkoutsk, and after running parallel to the Lena, takes a westerly course, when it joins the Yenisei near Turuchansk. Its course is estimated to be 1000 miles in length. The Middle Tunguska, after a course of between 500 and 600 miles, falls into the Yenisei in lat. 62° N. The Upper Tunguska contains a larger body of water than either of the other two. It originates in the southern part of Lake Baikal, and flows through a broken and rocky channel. It bears the name of Angara in the first part of its course, till after it receives the Ilim, when it is called the Tunguska. It then flows west, and joins the Yenisei in 59° N.

TUNICA, a kind of waistcoat or under garment, in use among the Romans. They wore it within doors by itself, and abroad under the gown. The common people could not afford the toga, and so went in their tunics; whence Horace calls them *populus tunicatus*.

TUNING-FORK, a steel instrument with two prongs and a handle, used to regulate the pitch of voices, or of instruments that require to be tuned.

TUNING-HAMMER, an instrument used by pianoforte tuners to twist round the iron pegs to which the wires are fastened at one end, or to fix these pegs by hammering them into their holes.

TUNIS, a country of Africa, bounded on the north and east by the Mediterranean Sea and the kingdom of Tripoli, on the south by several tribes of the Arabs, and on the west by the kingdom of Algiers and the country of Esab. It is 300 miles in length from east to west, and 250 in breadth from north to south. See Africa.

Tunis, a large town of Barbary, and the capital of the kingdom of the same name. It is seated on the point of the Gulf of Goletta, about eight miles from the place where the city of Carthage stood. It is of an oblong form, and is about four miles in circumference, with ten large streets, five gates, and thirty mosques. The houses are all built with stone, though but one story high; but the walls are very lofty, and flanked with several strong towers. It has neither ditches nor bastions, but a good citadel, built on an eminence on the west side of the city. Its population was estimated by Mr Blaquiere at 130,000. The harbour of Tunis has a very narrow entrance, through a small canal. In the city they have no water but what is kept in cisterns. It is a place of great trade, and is ten miles from the sea. Long. 16. 10. E. Lat. 36. 42. N.

TUNNEL. A tunnel is simply a hole bored through a hill, in order to carry a canal, a road, or a railway, in an advantageous course, and is generally resorted to as a means of lessening the expense which would ensue if an open cutting were made. There are other reasons which may render this mode of proceeding advisable; such as gaining the consent of a landholder, who would object to a cutting through his property, but would have no dislike to a tunnel; and various other local causes: but the general reason for such a mode of proceeding is the consideration of expense. In order to enter into this inquiry, the first step is to make plenty of borings, for the purpose of examining the geological structure of the proposed hill. If these are considered satisfactory, trial shafts should be sunk quite to the intended bottom, as by these the quantity of water to be expected will be discovered. It should be particularly attended to, as water is one of the greatest annoyances to be encountered in tunnelling. The readiest way is to measure the water into a cask, and ascertain the number of gallons per minute. To do it readily, the shaft should be about four feet in diameter, rather more than less; and no loss will be occasioned by making it large, as, if the situation is properly chosen, it may afterwards be converted into a working shaft.

The necessary power to drain being taken into account, and the geological structure of the ground being ascertained by the borings, we have thus the elements for making an estimate of the relative expense of forming a tunnel or an open cutting. Questions of expediency will also have to be taken into the account; such as, how the spoil from a tunnel can be deposited, and at what expense in the purchase of land; whether earth in large quantities is requisite for an adjacent embankment; and if we lose this by making a tunnel, at what price can a side-cutting be made to complete the embankment; and various other questions connected with the locality, which can only be determined on the spot. Sometimes the earth for the tunnel can be taken out laterally, the working shafts being horizontal; and in this case the work is called a gallery, and not a tunnel. This process will in general lessen the expense.

In the present state of civil engineering, a tunnel can be made through any object, from a rock to a quicksand; and the question of making it turns chiefly on the expense, which will vary from L.20 a yard in sandstone, which is easy to cut, and which will stand without brick-work, up to L.100 and L.140 a yard in quicksand and bad ground, requiring twenty-seven inches thickness in the brick-work, and mostly to be laid in concrete. The Thames tunnel has cost about L.1200 a yard. Here, however, there have been severe difficulties of a peculiar nature to contend with, and it is a double tunnel. In general the rocky strata will be cheapest, as no brick-work will be required. Hard shale, and in fact any thing which will not cut by a spade, is best removed by blasting, and not by the pickaxe. In some cases tough clays will be found, against which a pickaxe is nearly useless, as it merely indents a hole where it sticks, without loosening any thing. Blasting will have no effect on this: hatchets will answer very well, and cross-cut saws best of all. The borings should be numerous, so as to give all the strata. Chalk, for instance, will often contain large holes filled with gravel, which on being opened during the execution of the work, will pour in on the unsuspecting miner the water.

After due consideration, having determined on a tunnel in the place proposed, the engineer next decides on the size and shape, both being in some measure regulated by what the tunnel is intended to carry. But, as respects the shape, this is also dependent on the nature of the ground, and the degree of weight which the brick-work will have to support. For instance, in a wet quicksand, which approaches the nature of a fluid, with an equal pressure all round, the shape should approximate as nearly as possible to that of a circle; and for any other kind of pressure, the form of the tunnel should be proportionally modified. Curves and rises or falls should by all means be avoided if practicable.[1]

In setting out a tunnel, the engineer should have a transit instrument, placed in a fixed observatory, and standing on a pier insulated from the building; and if there is any road near it, the pier must be insulated from the ground to a depth of six, eight, or ten feet, according to the nature of the traffic on the road, in order to insure stability and a freedom from vibration. A distant mark should then be taken in the line of the tunnel, and a fixed point placed as the adjusting spot for the line of direction: the farther this is off the better. Intermediate marks for the working and ventilating shafts may then be set out correctly; and as these are sunk, plummets, suspended from points accurately set out by the transit instruments, may be constantly tried as to the proper direction. These plummets should be of iron, and should be let down into buckets of water, to check the vibration; or, what is better, they should hang in cups of mercury. When the shafts are cleared out to the bottom, other transit instruments may be placed in them, the plumb-line and transit being kept as far from each other as possible. The intersection of the vertical hairs in the transit with the plumb-line, will then enable the engineer properly to set out the work.

Tunnels have been known to draw water off the wells as far as a mile distant. This may generally be remedied in every case except that of a canal containing salt water, by sinking the wells deeper, which for the most part restores them to nearly their original state. When a salt-water canal is to pass through a tunnel, compensation had better be made to the parties as soon as it is discovered that an injury has been done. In all cases of canal tunnels, care must be taken that they are run deep enough to insure a proper supply of water to allow for waste, lockage, and leakage, where the supply is contingent on a tideway. It will be very expensive to remedy this afterwards, and will most probably require the erection of a steam-engine to pump up a sufficient quantity.

Some of the old canal tunnels, through an injudicious economy, were constructed without a towing-path. The boats are in these cases pushed through by men lying on their back on the deck, or on a projecting board placed for the purpose. They then set their feet against the side-walls of the tunnel, and advancing them alternately, foot the boat along, the helmsman steering against them. This barbarous plan, which has occasioned serious loss of life, is now generally abandoned; but no tunnel or canal can be called perfect unless it has a towing-path on both sides. In the tunnels, an iron hand-rail should invariably be set up next the edge of the towing-path; and if there is but one of these, its width should be so increased as readily to admit the horses to pass each other. Some of the old tunnels above described were completed for less than four pounds per yard; and one, the old tunnel on the Grand Trunk Canal at Harecastle, in Staffordshire, constructed by Brindley, only cost L.3. 10s. 8d. It was ten feet in diameter, and consisted merely of a semicircular brick arch, which sprung from the water-line of the canal. The variation in size from this may be judged of by the following examples on railways.

---

[1] When it is for a canal, the form is generally an entire oval, the lower portion forming the water-way; and on one or both sides a retaining wall is built, and filled in behind, to form the towing-path. Sometimes a wood camsheet is substituted for the wall, and cross sleepers laid on it. In a canal, of course, every thing must be level from lock to lock.

In the agreement entered into with the contractor, the price of the contract, and a schedule, by which any extra or additional works are to be executed, should be stated; and likewise the mode of payment, and the nature of any retentions. The time for completion, and fines for exceeding this time, should be clearly and distinctly laid down; with the condition that all payments are subject to the engineer's approval of the work. The contractor should find all tools, machinery, labour, and materials of an approved kind, getting out all foundations, excavations, shafts, culverts, drains, roads, &c.; and he should provide all centrings, coffer-dams, pumping apparatus, scaffolding, fencing, and other requisite materials of every description, according to the specifications, plans, and drawings, and the instructions which he may from time to time receive from the engineer. In the case of a railway, he should lay the permanent way, the materials being in this case found for him; and in a canal he should construct all the locks and gates, if there are any at either end of the tunnel, and form the towing-path. When he does not employ a sufficient number of men on the work, the engineer should have power to engage more, after giving him a week's notice of his intention. These may be retained temporarily or permanently, as may be required, and in all cases using the contractor's materials, the men's pay being deducted from the price of his contract. The engineer should also have the power of ordering the discharge of any foreman or workman acting improperly, or doing his work with carelessness; a power which he should be cautious not to use without strong reasons. The ground over the tunnel should be fenced off previously to commencing the work. The contractor should be restricted from entering on any adjoining land without leave; and if this should be necessary after the leave is obtained, the required land should be immediately fenced in. Temporary roads, for the conveyance of materials from the high roads, when required, should be formed by the contractor; as also those necessary for conveying away the spoil-earth. If the company who are forming the tunnel are called upon by any of the surrounding occupiers, they should have power to compensate them for any damages, and to place the sums thus paid to the contractor's account.

The contractor should not be allowed to sublet any portion of the work without permission in writing from the engineer. He should also be bound to take down or otherwise alter any work not approved of by the engineer, and to remove all unsound materials. All materials, from the moment they are brought on the site of the works, become the property of the persons for whom the tunnel is made, and the contractor must not remove them again without permission; but the company or other persons making the tunnel are not to be answerable for the damages which any materials may sustain. These and similar clauses in the agreement, are of course only provided for cases of emergency, and would seldom require to be acted on. The contractor should make all the alterations and additions which he may be instructed to do by the engineer, and no others. He is to be furnished with copies of the plans, sections, and other drawings, also of the specification, and is himself to see if these are correct; he is also to do all that may be reasonably implied, although not actually expressed, in the drawings and specification. It is usual to deduct ten per cent. from the payments; the whole of which is not returned to the contractor till twelve months after the completion of the work, he being bound to keep it in repair for that length of time. The payments are in general made monthly, including those for extra and additional works, after being approved by the engineer, who is to certify the same. It is also usual in large works of this kind, when the contractor has more than two millions of bricks on the site of the work, to allow him half or two thirds of their cost.

When the tunnel is for a railway, the company deliver the permanent-way materials at the nearest convenient place, and the contractor brings them to the works, defraying the charge of wharfage, if any. In the event of any disputes, the decision of the principal engineer is in all cases to be final.

The drawings should consist of, 1. a general section of the tunnel longitudinally, containing all the measurements to an exact scale; the positions of any ventilating shafts if such are required; their length, breadth, thickness of brickwork, &c.

2. Views of the fronts and wings, with plans and sections of the foundations and wing-walls, showing the curves and batters.

3. Plans and sections of the ventilating shafts, and the iron-work connected with them on the working shafts.

4. Transverse sections of the tunnel, with any other details as to drains, and all other necessary information; and plan and section of fronts.

5. A general plan of the property through which the tunnel passes, showing the width to be fenced in.

6. If for a railway, plans of the rails, blocks, and the mode of laying them. If for a canal, plans of the locks and gates, with all other necessary details.

The specification should define in words the situation and termini of the tunnel, and the number and dimensions of the locks, if for a canal; and should then enumerate the various works, such as fencing off the ground above, one chain in width, till the tunnel is completed; sinking ventilating and working shafts; excavating and building the tunnel; building the fronts; laying the drainage; excavating in open cutting at each end, if required; forming and turfing the slopes, and fencing and ditching them, and the tops of the fronts; depositing all the earth in a given place, so as, when soiled, to be fit for agricultural purposes; ballasting and laying the way, if for a railway; but if for a canal, making all the necessary locks and feeders, forming the towing-path, building lock-houses, deviating roads if required, and keeping the whole in repair for one year.

The temporary fencing should be on each side of the tunnel one chain in width, between which all work and materials are to be comprised. It should be of split oak posts nine feet apart, mortised for the reception of three horizontal oak or larch bars; the posts three and a half feet above ground, and the bars having one intermediate stay or prickpost firmly nailed to each of them. This fencing should be substantially fixed previously to the commencement of any other work, so as to exclude sheep and cattle from the intermediate space, and protect the surrounding land from damage. On the outside of the fencing a ditch should be formed, four feet wide at the top, one foot wide at the bottom, and one and a half foot deep, communicating with any existing water-courses or drains, so as effectually to prevent any of the shafts which may be sunk from injury by the overflow of water during the progress of the work. The strictest attention should be paid to this stipution near every shaft; and should the situation of any haft require for its protection a larger ditch in the line of ncing, or a puddled ditch round its site, the contractor ould be required to make it at his own cost.

When ventilating shafts are necessary, they may be built any required size. In railway tunnels from 2000 to 500 yards long, two shafts sixty feet diameter will be suf- ient. They are best built from the top; for instance, cavate ten feet down, and build the shaft for that height, en divide the circumference into parts about ten feet de, and excavate every alternate one of these, leaving the hers to support the ring of brick-work; and when these al- rnate ones are bricked up to the ring above, the remain- g earth is all taken away, and the bricking continued till e second ring is completed and connected with the first, en the same process is repeated till the whole is con- nued to the required depth.

The thickness of the brick-work is of course in propor- n to the size and height. For a shaft sixty feet diame- r and 120 feet high, the following would be sufficient in favourable ground. The tunnel, where the shaft inter- cts it, should be entirely of stone, and on this a course of one four feet square, on which the shaft stands; then the st forty-six feet to be three feet thick; the next seven- en feet, two feet eight inches thick; the next seventeen et, two feet three inches thick; and the last or upper xteen feet, one foot ten inches thick, coped with stone for e railing. The boundary wall might be one foot one and half inch thick, with footings, and an increase in the foun- tions, if thought necessary.

They should be built in alternate courses of headers and etchers, each brick being well flushed up; and where e tunnel intersects the shaft it should be faced with stone, ch stone to be eighteen inches upon the curve of the ffit, toothing into the brick-work in the soffit of the tun- l by being three and four feet long alternately; the whole ly fitted in their beds, and neatly hammer-dressed, each ing secured to the adjoining one with malleable iron wels run in with lead.

Stone coping should be set upon the shafts a little above e level of the ground, into which iron railing may be xed. The stones to be secured by lead joggles, three urths of an inch square, and run one inch into each stone. he iron railing should be about three feet high, of malle- le iron, three fourths of an inch square, and five inches stant from centre to centre, set three inches into the cop- g, and run with lead. A half-round hand-rail should riveted on each upright, an inch and a half wide, as a ish.

Shafts of the above size should be enclosed with a circu- r wall seventy-two feet in diameter, twelve feet high, and urteen inches thick, with a plinth of eighteen inches, and stone coping sixteen inches wide and four inches thick, eathered and throated. In this wall there should be a orway. The space or path between the wall and the aft should be paved with bricks, having a gentle slope twards, with holes through the wall about every three et, to let out the water.

The whole bottom of the shaft should be soundly filled , sufficiently deep, with good concrete beaten firmly down; d whenever the excavation is larger than the dimensions the shaft, the space should be filled perfectly solid with rick-bats, and grouted with Roman cement, with which e shafts are to be built; but the enclosing wall may be uilt with mortar. Whenever water occurs in sinking any f the shafts, it must be completely excluded from them by lining of puddle, or Roman cement if necessary.

In short tunnels it may sometimes be advisable to drive heading, about four feet wide and five feet high, right hrough, before excavating it; and the contractor should e allowed to sink what air-shafts he thinks proper, provided they are not in the line of any road, nor within fifty feet of any working shaft. They may be from three to four feet diameter in the clear, supported on iron curbs, carried up ten feet above the surface, and coped with stone.

To determine the number of working shafts, regard must be had to the time allowed for the completion of the work, and the nature of the part to be excavated. The shafts must be just so close together that every face can be raised and bricked half the distance to the next shaft, two months before the given time for completion, leaving these two months for building the fronts, and laying the way if for a railway; and in all cases a larger allowance had better be made, in case of accidents.

The number having been determined on, their places should be shown on the drawings. They should be nine feet in diameter inside, and nine inches thick; the bricks to be all heading, and to be well bedded in Roman cement. The shafts should be kept free from all bulges and imperfections; they should rest on an iron curb-ring, forming a key between the bottom of the shaft and the top of the tunnel; and they should be carried up ten feet above the surface, and coped with stone.

In excavating where the ground is bad, the contractor should not, without permission, advance beyond the completed brick-work more than six feet. Ten feet will in most cases be a convenient length; but in this the engineer must form his judgment from the nature of the ground. The space excavated must be well secured, in the manner to be hereafter stated. The dimensions of these supports are to be approved of by the engineer. The invert, sides, and roof, should be cut out as nearly as possible of the size the tunnel will be when finished. When more than this is taken out, it should be securely made good; in every case one man being employed at each face solely in filling and ramming in, if under the invert, with well-pounded clay, and if on the sides or top, with suitable materials, rammed in with every other course of bricks at the sides, and, as soon as the succeeding excavation will allow it, at the top. But when the ground is very bad, the bars are to be left in, at the pleasure of the engineer. The cills should not in general rest on the brick-work, but on trestles, so as to be independent of the side-walls. If this is not done, the holes where they have rested should be made good, whenever they are withdrawn, with brick and cement.

When any two faces are within fifty yards of each other, a heading should be driven to connect them, and insure the proper direction of the line at the junction. The contractor should also be bound to drive any headings the engineer may direct, either for drainage or otherwise. The engineer should, at the contractor's expense, from time to time give the contractor marks, in the way to be hereafter shown, to let him know how the line of the work is to be regulated.

Twenty-seven inches thick in the sides and top, and eighteen inches in the invert, in Roman cement, will be the most ever required, even in a quicksand; and as the nature of the ground improves, this may be lessened, till we arrive at the point where it will stand of itself. Each brick should be well bedded with a wooden mallet, and every joint thoroughly flushed when mortar is used. When the shape of the tunnel requires it, the bricks must be moulded taper. In the arch they are laid in concentric rings, half a brick thick, taking care that the additional number of bricks requisite for each additional ring is put in, which is easily calculated. In a tunnel twenty-seven feet high, and twenty-three wide, it will be five more for every ring. A course of stone should be laid in at the springing of the side-walls from the invert; the stones about three feet long, well bedded in mortar, on four courses of very sound and hard bricks.

It will generally happen that excavations are to be made at each end after the tunnelling has sufficiently advanced. These excavations should be turfed, if possible, as soon as they are finished; and if turf is not to be had, they must be soiled at least eight inches thick, and sown at the proper season with equal parts of rye and clover seed, in the proportions of three pounds of the mixed seed per acre.

The top of the slopes and the ends of the tunnel should be protected with a ditch, a wood-railing, and a line of quicks. The ditch should be five feet wide at the top, two feet deep, and with slopes that will stand according to the nature of the soil, which, if very bad, will render it necessary to widen the top. The earth from the ditch will form a mound to be neatly turfed, having the best of the vegetable soil in its middle, where a double row of three years old quicks, two years transplanted, should be set in the proportion of twelve quicksets to a lineal yard. The fence of split oak is to be set on the inner edge of the ditch, as before described. The quicks should be weeded and cleaned twice a year, and others planted in the room of those which have not taken root.

A brick drain should be laid the whole length of the tunnel, in Roman cement, with the end-joints open half an inch for the passage in of water from the ballasting; and if the shafts let in water, a conveyance half-round pipe must be fitted to the bottom of them, to lead the water down the side of the tunnel into the drain.

With respect to the spoil, if made into banks, the turf should first be removed, to be afterwards put on the top. Convenient sites should be found, so that the spoil shall be useable for agricultural purposes; and where turf enough to cover it cannot be had, it must be soiled and sown with seed at the proper season.

All damages to the adjoining land must be paid by the contractor; but if the parties making the tunnel are, as is usually the case, a public company, under an act of parliament, they should assist the contractor in getting the necessary land, with the powers of their act. It is understood that the contractor has the full use of the one chain in width along the line of the tunnel, free of all charge, on which to erect any buildings or machinery he may require, laying railways or roads for conveying away spoil and bringing in materials, lifting-engines, pumping-engines, or any other apparatus; and it is also understood, that if any material turns up fit for making bricks, he is to have the advantage of applying it to that purpose.

In case of having any roads to divert, or new ones to make, the ground should be excavated the required width, and one foot deep; when, if it is moist, brushwood should be placed upon the bottom, and then gravel, till the centre, when the whole is well beaten, is two feet above the excavated bottom, with a rounding of six inches on the surface. None of the gravel or broken stones should be larger than will go through a two-inch ring. A ditch, railing, and quicks, as before described, are then to be put up.

The engineer is in all cases to be the judge of the thickness of the brick-work, which should be provided for in the schedule of prices; as also, whether laid in cement or mortar. It should also be clearly defined whether or not the contractor is to be liable for any damage done to the land from the falling of the surface during the execution of the works, or if the regular continuity of the brick-work is destroyed, arising from irregular shrinking or settlement in the arch, imperfection in the centring, or any other cause. He should also be bound to remove all the temporary fencing, and clear the surface after the works are completed.

The materials should all be of the very best kind. The bricks should be sound, hard, and well shaped, being moulded taper wherever the form of the tunnel requires it. The sides may be built in English bond, or alternate heading and stretching; but the arch and the invert must be in concentric half-brick rings. The mortar should be of the best lime and sharp sand, in the proportions of three to one, and passed through a pug-mill, the lime being ground under edge-stones in its dry or unslacked state. The Roman cement should be perfectly fresh burnt, and capable of setting hard; it should be mixed with an equal quantity of sand, and none used which has set. The stone should be of a sound and hard quality, perfectly free from flaws. The cast iron employed in the curbs for the shafts should be of the best No. 2 iron, and the castings perfectly clean and cleared from air-bubbles or pin-holes, and no stopping or packing should be allowed. The whole of the malleable iron-bolts, &c. employed, should be made of the best scrap-iron. The bolts for retaining the tunnel fronts should be tested to twenty-five tons, and tested in pairs to try the couplings. When concrete is used, it should be five measures of clean riddled gravel, and one measure of lime, and not mixed till immediately before it is required to be placed in its intended situation.

There should be a specified time for the contractor to begin and finish each portion, such as the working shafts, the ventilating shafts, the excavation, &c.; and he should be bound to execute a given quantity of tunnelling per week, sending the engineer a weekly return of all descriptions of men employed on the works, distinguished into classes.

When the rails, chairs, blocks, and other permanent-way materials are delivered to the contractor, he is then responsible for them. They need not be delivered till the tunnel is complete. Ballasting is to be used of broken stone or gravel for bringing up the blocks to the required height, without any mixture of clay or other substance capable of containing water; it should set quite hard. If broken stones are used, they should be passed through a two-inch ring. The ballasting, which may, if required, be shot down the shafts, an inclined plane at the bottom canting it the right way, should be spread over the invert, and beaten into a firm and solid mass, by means of heavy beaters, worked by at least two men, till it is consolidated at the proper height to receive the blocks or sleepers, which are also to be imbedded as firmly as possible. The contractor will have to drill two holes in each block to receive the treenails, and to cut a proper bed for the chairs on the sleepers. No spikes should be driven into sleepers till proper holes are bored. The sleepers should be imbedded by beaters, and the blocks by lifting them one foot high by a spring lever, and then letting them fall till no difference of level is perceived. The rails must be laid perfectly level and parallel, and the joints even and true, with an allowance for expansion and contraction suitable to the temperature to be furnished by the engineer. The utmost care and attention should be paid to so essential a point as the laying of the permanent way.

In excavating the working or ventilating shafts, it will be the best method to sink with a roll till they are fifty or sixty feet deep: this is worked by hand, and then with a horse-gin. Fig. 13, Plate CCCCXCIV. If the ground is hard, the roll should be used longer, as this will be the cheapest way. The roll is worked by two men, and if they have to stand still occasionally for the bucket, or skip as it is termed, to be filled, it will be a less expense than if a horse, horseboy, and bankman (to land the skip), have to wait for the fillers. In working rocks, they will frequently have to wait for the blast.

A working shaft of nine feet diameter will be found sufficient; and in commencing it, place four cills across, as represented in the drawing, fig. 13, about twelve or fourteen inches square. On them place the standards for the winch, as shown; then begin the excavation, going on till the ground discovers signs of weakness; then put in a curb (*a*), which is a wooden ring the size of the shaft, three inches thick, and as wide as the intended brick-work, for which four inches and a half will in most cases be sufficient. But if the ground is very soft, cut back into it and make the curb wider; then brick the shaft from the curb to the top, and go on excavatng down the dotted line (*cc*), leaving the earth at (*cc*) to upport the curb (*a*). Timber props (*d*) may also be set up or further support, if thought necessary.

When the ground again shows signs of weakness, exca- ate inwards, as at (*a*), and filling up with another curb, pro- eed as before, according to the nature of the ground. Tak- ng out one fourth, one sixth, or one eight of the circum- erence, and putting in the same quantity of the curb, brick up to the curb above, and then take out another portion f the earth; or, if possible, proceed in pairs.

When it is found expedient to use the gin, two pulleys ust be fixed, as shown in the drawing, fig. 13, for the rope run over, and the supports or standards made proportion- ly stronger. Having in this way completed the working hafts, the next process is to sink down to the bottom of the unnel: it is of no consequence whether enough is taken out or the invert or not. The excavation should then be com- enced at the top of the tunnel, first running a heading at e upper part, a little exceeding the length intended to be t in. This length must depend entirely on the nature of e ground, varying from three to fifteen feet up to rock, hich wants no brick-work. The excavating is then conti- ued downwards from the heading; and when got out, the rth is propped up by the mining centres, mostly composed round timber, as shown in Plate CCCCXCIV. All this opping is above the centring; it is composed of two cills a), fig. 10, close to the face of the tunnel, between which e the props (*bb*). These cills might be fastened by an earth- rew (*c*), fig. 16, worming into the face of the tunnel. The own and side bars (*dd*) are then introduced: the two upper es are called crown-bars, and all the rest side-bars. The ick end of the bars rests on the props, and the smaller d on the last length of brick-work in the tunnel. From ch cill stretchers (*ee*), fig. 16 and 10, are fixed, the other d taking the last brick-work; also raking stretchers or kers (*ff*), figs. 10 and 16, the ends of which are let in as to have a firm hold on the last brick-work. The lls may be from twelve to fourteen inches square when e ground is bad; the crown-bars fourteen inches diameter the thick end, the stretchers, rakers, and props, being in oportion; and their thickest ends placed as shown in the awing, reducing their sizes in better ground. It is advis- le to buy the timber whole, and cut it up according as e strain is found to vary.

The number of side-bars depends entirely on the nature the ground. Sometimes they will only be required down the top cill, and in other grounds they must be carried own to the invert. Sometimes, when, from the weight of e face, it is seen that many stretchers must be used, three lls are put in. The props also to the crown and side bars ary with the pressure; and for this purpose, they are made to diate to a point, which changes accordingly. Thus the prop), fig. 10, would in rock be perpendicular; and if the ground the prop (*h*) was bad, and likely to come in, the prop (*h*) ould be inclined in the position of the dotted line. The ops between and under the cills are all perpendicular; etween each crown and side bar there are stretchers to eep them apart at the proper distance. When the prop- ng is completed, the next object is to get up the centring r the brick-work (which is formed in the manner shown fig. 15), of the required shape for the tunnel, leaving a ace just enough to take the brick-work and laggins be- een the centring and the propping apparatus. The in- ert is the first thing built, then the side-walls, by means of e leading frame (*ff*), which goes up to the springing, hav- g supports (*gg*). This leading frame, which is in fact a mplate, is set up next the face of the tunnel, and from it e bricklayers string their lines; and when finished, the ading frame takes to pieces, and is got out till a new ngth of the work is excavated, and it is then put together s before.

When the side-walls are raised to the springing of the arch, a cill (*e*), fig. 15, is built in with them; then the centring, which, with its cill (*i*), is all fixed together, is got up and wedged to the required height. The laggins (*kk*) are pieces of quartering which go from centre to centre, and on them the bricks are laid; (*cc*) are the queen-posts, (*d*) is the straining-piece, (*aa*) principal beams butting against (*b*), (*mm*) are the ribs on which the laggins lie; and if the centring is large, these may be joined over the queen-posts and struts.

In some rare cases the cill (*e*) is not laid on the side-walls and bricked in, as leaving a hole would, if the weight was great, be dangerous. Whenever this happens, trestles are set up from the bottom to support the cill (*e*).

Sometimes in quicksands or other bad ground, a slip will happen, in spite of all exertions to the contrary. This occurrence will perhaps take place, if the rakers are not got up, although the crown-bars, side-bars, and cills are up. It arises principally from a pressure on the face, throwing the cill back and letting the bars down. When it does happen, a shaft must be sunk from above, and the ground beaten perfectly firm and solid from bottom to top, and the work then proceeded with as in any other new length. The slip will often extend to the surface, and will then take the appearance of a hollow dome.

In the upper portion of the arch, where the bars cannot be withdrawn, and the vacancy between the brick-work and the excavation filled up and rammed in till the completion of the brick-work, it should invariably be done at the very earliest possible period, which will be when the next length of excavation has proceeded far enough to let the workmen have sufficient space to perform it with soundness; and whenever the material through which the tunnel is making is of so bad a nature as not to admit the withdrawal of the bars and planking, without a risk of disturbing either the form or stability of the brick-work, they must be left in, according to the judgment of the engineer; consequently their value should invariably form an item in the schedule of prices under which the contractor is constructing his work.

Tunnelling under rivers presents considerable difficulty, as has been experienced in that under the Thames. The first tunnel was commenced at Gravesend in the year 1799, but the scheme was speedily abandoned. In 1804 another was commenced from Rotherhithe to Limehouse; but after sinking an eleven-feet shaft forty-two feet, the difficulties were such that the work was suspended. The diameter was then reduced to eight feet, and at seventy-six feet deep a drift was carried 923 feet under the river, which was only 150 feet from the opposite shore: the engineer then reported that farther progress was impracticable. Several other plans were devised, till in 1823 Mr Brunel proposed his for a double tunnel between Rotherhithe and Wapping, the soil there being a tenacious blue clay. The Rotherhithe shaft is fifty feet diameter 150 feet distant from the river, being forty-two feet high and three thick, built on the surface and excavated afterwards; the earth and water being drawn out by a steam-engine on the top. It was thus sunk in its place in a body, and by this means passed through a bed of gravel and sand twenty-six feet deep, which had caused great inconvenience in the former attempt. See fig. 11.

The fifty-feet shaft was sunk sixty-five feet, and from the lower level a twenty-five feet shaft was sunk to eighty feet for drainage. At sixty-three feet the tunnel commences dipping two and a quarter feet per 100 feet. The excavation was thirty-eight feet wide and twenty-two and a half high, or a sectional area of 850 feet; and the bottom, at the deepest part of the river, is seventy-six feet below high water. The excavation was effected by a shield composed of twelve frames close together, having each three cells above one another for the miners (fig. 18): 400 feet were bricked

Tunquin.

complete in ten and a half months. In May 1827 and January 1828 the river burst in. These accidents were overcome by throwing down bags of clay from above. The work was however suspended for several years, not from any doubt of its success, but from want of funds. It has again been commenced, and has now reached the wharf-wall on the Wapping side.

The shafts will contain easy flights of steps for foot-passengers, and the descents for carriages are intended to be circular, to give them an easy slope. The middle wall was first built solid for greater strength; but openings were then made, so that each tunnel has ready communication with the other. The entire length will be 1300 feet. During the excavation each portion of the shield advances separately; and in front, polling boards are pressed firm against the earth by screws. These boards are removed singly to excavate, and the first is always replaced before a second is taken down. Fig. 17 shows through the tunnel a view of the twelve parts of the shield as worked. They, of course, are all of a length, extending to the outer parts of the brick-work in all parts.

In Plate CCCCXCIV., fig. 14 shows the mode of supporting the shafts in a canal or railway tunnel when finished, by the iron curb, separate drawings of which are given in figs. 6, 7, 8, and 9; fig. 12 shows the mode of drawing the curves for the tunnel exemplified in North Church Tunnel on the London and Birmingham Railway; fig. 5 is the front of Stowehill Tunnel; fig. 1 is the front, fig. 2 is a section of the wing-walls, fig. 3 a section through the centre, and fig. 4 plans at top and bottom of Linslade Tunnel. All the figures are to the same scale, that under fig. 11; except figs. 17 and 18, which are to the scales near them. (B. H.)

TUNQUIN, or Tonquin, a large kingdom of India beyond the Ganges, bordering on the Chinese provinces of Quangsee and Yunan, and separating that empire from Cochin-China and Cambodia. It is situated between the seventeenth and twenty-third degrees of north latitude. It is bounded on the east by the Gulf of Tunquin, and on the west by Laos, Lactho, and part of the province of Yunan in China. This country is of an extremely diversified surface. The districts to the north and west, towards China, are wild and mountainous, with no very distinct boundary; and the breezes from these heights, and towards the sea, always preserve a tolerable degree of coolness. Mountains, extending from east to west, separate Tunquin into two divisions, of which the northern is considerably larger than the southern. A prolongation of these ridges separates Lactho from Laos, and others separate Tunquin from Cochin-China. These mountains are of great elevation, and many of them terminate in sharp peaks. The central part of the country consists of a vast alluvial plain traversed by numerous rivers, chiefly tributaries to the great river called Saigong, which flows through the whole breadth of Tunquin, and on which all the principal towns are situated. The seasons or monsoons are here, as in other tropical countries, divided into wet and dry. The rains begin in May and end in August, and are accompanied with thunder loud and terrific. There are few countries better supplied with water than Tunquin and the lower parts of Cochin-China. The country of Tunquin is watered by above fifty rivers that flow towards the sea, several of which, by their union, form the large stream which passes Backing. This river, which was navigable about 150 years ago, when Dutch vessels ascended the stream to within fifteen leagues of Backing, has now thrown up many islands, and its mouth is so obstructed by a bar of sand, that the Chinese junks which trade to this country can no longer ascend the stream. The country is inundated and rendered fertile by the tropical rains, and thus yields ample crops of rice and other productions. Potatoes, yams, and other roots, furnish also a copious supply of subsistence. The usual tropical fruits abound, such as mangoes, lemons, cocoa-nuts, ananas; and the most delicious oranges, as also the peach, the plum, the pomegranate, and the citron, are produced. The tea-plant is almost as common as in China, but not being attended with the same care, is not so valuable. The areca, the betel, the indigo, the sugar-cane, also grow in these fertile plains. Vines have been planted, but the grapes do not come to maturity. Mulberry trees are plentiful, and supply food for silk-worms. The country also contains much large timber fit for building; beautiful cabinet woods, such as eigle wood, cocoa-nut, and other palms, bamboos, and rattans. There are mines of various metals; and iron ore is procured in a state of great purity. It is also asserted that there are tin-mines in the mountainous tract towards China, the working of which is prohibited. Particles of gold are found in many of the Tunquin rivers, and salt and saltpetre are in great plenty and of good quality.

Among the wild animals to which the woods afford ample cover, are found the elephant, which is the property of the monarch; and the buffalo, which is employed for agricultural purposes. Neither the sheep, nor the ass, nor the hare, nor the camel, is known; but the hog and the goat are abundant. The horses are a contemptible breed. The rhinoceros is occasionally discovered, and tigers of the largest size are found. There are bears of a diminutive species, and deer and monkeys of all sorts. The country is much infested with rats, and with reptiles and insects, some venomous, others innocuous. Fish are remarkably plentiful, and furnish the inhabitants with a greater supply of food than they derive from the terrestrial animals. In addition to the common sorts of fish, there are turtles, tortoises, crabs, shell-fish, and moluscas, the substance of which is gelatinous, and greatly relished by the Chinese, however distasteful to European palates. Ducks and poultry are numerous, and very cheap.

The trade of Tunquin can hardly be described as very considerable, and it is chiefly carried on by merchants from China and Siam. The chief manufactures to be obtained at Tunquin are silks and lackered ware. The silks are both raw and wrought; they are very beautiful and cheap, while the lackered ware is scarcely inferior to that of Japan. Gold may also be obtained in considerable quantity. Other articles of export are earthenware, drugs, Chinese paper, dyeing woods, musk, rhubarb, tortoise-shell, ginger, cassia, ebony, ivory, sugar, and molasses. In the seventeenth century the Portuguese, Dutch, English, and French, had factories in Tunquin; but they have been long since abandoned. At present the Chinese experience greater favour than any other nation, and are allowed to ascend the rivers; a privilege also granted to the Portuguese at Macao; but neither are allowed to establish factories on shore. In Tunquin there are reckoned to be twelve principal cities; namely, Backing, or Keeho, said to contain 40,000 inhabitants; Hanring, 15,000 to 20,000; Tranhac, 10,000 to 15,000; Causang, 7000 to 8000; Vihoang, a town on the river that passes through Tunquin, up to which the Chinese junks can ascend; Hunnam, a town on the same river, containing about 5000 inhabitants. There are, besides, six other towns containing from 6000 to 7000 souls.

Tunquin is divided into ten districts, of which the central district, named Xunam, is by far the most populous, consisting of a vast plain, watered by numerous navigable streams, and in the density of its population resembling a Chinese province. We have no data for any accurate estimate of the population of the country. It has been computed by a missionary at eighteen millions; but this is probably far beyond the truth. One tenth of the inhabitants are supposed, like the Chinese, to live constantly on the water. The Tunquinese, deriving their origin from the Chinese, are distinguished by a general resemblance to them in their language and manners. Their language is a odified dialect of the Chinese, but so greatly changed nd corrupted, that the spoken language is now wholly un- ntelligible to a native of China, though the written charac- er is understood, being the same in both countries. Print- g is known in Tunquin, but the people generally are rude nd uninformed; such limited knowledge as they possess eing confined to the mandarins. Their printing is of the dest kind, their types being of wood, and not moveable; ut being rather a mode of stereotype, and every additional ook requiring new plates and characters, few are printed, nd these have in general a reference to religion and law. he historical works are inaccurate; those on moral subjects re mostly translations from Chinese works, or commenta- es on them; and the sciences have remained stationary r nearly a thousand years. The people resemble the Chi- ese in their shape and features; but the additional prac- ce which they have adopted of blacking their teeth, gives hem a hideous appearance. The blackness of the teeth is, owever, considered as singularly ornamental, and takes lace generally at the age of sixteen or seventeen. Like e Chinese, they allow their nails to grow to an immode- ate length. They differ however from the Chinese in eir laborious habits, being extremely indolent, and not sily roused to any vigorous exertion; and their task be- g accomplished, they soon relapse into their former state sloth and repose. They are remarkably coarse in their ode of eating, using for food what among other nations is jected with disgust. Not only are particular parts of the inoceros and the elephant eaten, but grasshoppers, mon- eys, horses, and dogs, with mountain rats, lizards, and ome kinds of worms and snakes. They refuse the milk animals in any shape, holding it in extreme aversion. hey have the same repugnance to fresh eggs. They eat l manner of odious reptiles and noxious animals, and refer drinking water in a tepid state. Their laws and stitutions bear all the marks of a rude and barbarous eople. Punishments are decreed against all sorts of crimes ith particular minuteness, but with little discrimination, eing not at all proportioned to the nature of the offence; ose against manners being more rigorously punished than rimes dangerous to society. There is no proper security r natural rights; nor is life and property protected against e despotic rule of the emperor. It is dangerous, for ex- mple, to excel in any profession of art, as the talents of e artificer are immediately put in requisition to work gra- s for the emperor, or the governor of a province, or even ny common mandarin. They are restrained in many cases y a species of sumptuary laws. The bulk of the people are ot allowed to build their houses of stone, or more than one tory high; and the larger edifices, such as temples and pa- ces, are generally constructed of wood, or of wood and rick mixed. The roads are generally very bad, there be- g only one of a superior description from Backing, the apital of Tunquin, to the capital of Cochin-China, a dis- nce of nearly 500 miles.

Their religion is a modification of the Buddhist system, early resembling that which prevails in China, but blend- d with many local and peculiar superstitions. The higher lasses are described as adherents of Confucius, who sub- it to the worship of images and other ceremonies through eference to public opinion. Some of the more barbarous ribes worship the tiger and the dog. To the first, human esh is offered, and other disgusting oblations to the latter. races of the same worship are to be found among the ountaineers on the borders of India, as well as among the ndo-Chinese nations.

The Christian religion was first introduced by the Por- uguese about the beginning of the seventeenth century, nd subsequently by the French, while they had commer- ial establishments in the country. At an early period the Jesuits sent missionaries into the country, and had made considerable progress when they were expelled. During the eighteenth century, the exercise of the Christian religion was generally prohibited, and at particular periods persecuted with the greatest cruelty. In later times, the missionaries have suffered more from the mandarins and inferior officers than from the emperor.

Tunquin, along with Cochin-China, Cambodia, and Siampa, are recorded to have anciently formed part of the Chinese empire; but on the Mogul invasion of China from Tartary in the thirteenth century, the Chinese governors of Tartary took that opportunity to throw off the badge of dependence. In this manner several distinct kingdoms were created, the rulers of which continued to acknowledge for many years a nominal subjection to the authority of China. The Tunquinese rulers gradually assumed a greater degree of independence, and, about 1553, are said to have extended their dominion over Cochin-China. The subsequent history of this country is confused and obscure, consisting of a series of assassinations and revolts, and a perpetual fluctuation of boundaries. A revolution commenced about the year 1774; and it terminated after a sanguinary warfare of twenty-eight years, leaving the empire as it at present exists. Tunquin was finally conquered in 1800 by the emperor of Cochin-China, and has ever since continued under the delegated authority of that sovereign. (F.)

TUPPEL, a town of Hindustan. in the province of Delhi, situated on the east side of the Jumna, forty-seven miles south-south-east from the city of Delhi. Long. 77. 30. E. Lat. 28. 5. N.

TUPTEE, a considerable river of Hindustan, formed by the union of numerous streams. It has its source near the village of Batool, among the Injardy Hills, whence it pursues a westerly course through the provinces of Khandesh and Gujerat, until it falls into the sea about twenty miles below Surat. It has a bending course of 500 miles, through a fertile country, which produces much of the cotton that is exported from Surat and Bombay.

TURA, a small river of Irkoutsk, in Asiatic Russia, which rises in the district of Nertschinsk, and falls into the Ingoda.

TURBAH, a town of Hindustan, in the province of Bahar, district of Chuta Nagpore. Long. 85. 5. E. Lat. 22. 32. N.

TURBAN, the head-dress of most of the eastern nations. It consists of two parts, a cap, and a sash of fine linen or taffety artfully wound in divers plaits about the cap. The cap has no brim, is pretty flat, though roundish at top, and quilted with cotton, but does not cover the ears. There is a good deal of art in giving the turban a fine air; and the making of this article is a particular trade. The sash of the Turks' turban is white linen; that of the Persians' red woollen. These are the distinguishing marks of their different religions. Sophi king of Persia, being of the sect of Ali, was the first who assumed the red colour, to distinguish himself from the Turks, who are of the sect of Omar, and whom the Persians esteem heretics.

TURCÆ or TURCI, supposed to be the *Tusci* of Ptolemy, whom he places between Caucasus and the Montes Ceraunii. The name is said to denote, "to desolate or lay waste." See TURKEY.

TURCOMANS, a nomadic Tartar race, who are spread over many districts of Western Asia. Their native seat seems to be in the regions east of the Caspian, in the vast plains between it and the Aral. In their wars with the Kalmucs, the latter often proved victorious, and they were in consequence forced to fly into the Russian governments of Astracan, Oufa, and Orenburg, and there they continued to reside till the year 1770, when they succeeded in freeing themselves from the Kalmuc yoke. The wandering tribes, who range over the unclaimed space that lies between the territories of Russia and China on the west

Turgot.

and on the east, and which on the south is bounded by the kingdom of Persia and the lofty central mountains of Asia, are also known under the denomination of the Turcomans. These have from time immemorial followed a purely pastoral life, wandering from place to place, as the choice of pasture guided them, and have employed themselves entirely in feeding their flocks and herds, their whole means of subsistence, and who can never be persuaded to reside in towns or villages. They claim a hereditary right to the extensive and uncultivated tracts which they occupy, and which, being unfit for agriculture, and never having been the seat of a stationary population, afford to those who take advantage of them a sustenance for their cattle. For further details of this and the other barbarous tribes who occupy these tracts, see the article TARTARY.

TURGOT, ANNE ROBERT JACQUES, Baron de l'Aulne, a celebrated philosopher and statesman, was born at Paris on the 10th of May 1727, of a very ancient Norman family. His father was a long time provost of the corporation of merchants, during which he was the object of general admiration on account of his prudent administration. Turgot was the youngest of three brothers, and was destined for the church. He had scarcely attained the age at which reflection commences, when he resolved to sacrifice all temporal advantages to liberty and conscience, and to pursue his ecclesiastical studies without declaring his repugnance to their proposed object. At the age of twenty-three years he took his degree, and in December 1749 was elected prior of the Sorbonne. The time when it was necessary for him to declare that he would not be an ecclesiastic was now arrived. He announced this resolution to his father by letter, showing the motives which induced him to decline the clerical profession. His father consented, and he was appointed master of requests. He prepared himself for this office by particular application to those branches of knowledge which are most connected with its functions and duties, viz. natural philosophy, agriculture, manufactures, commerce, &c. About this period he wrote some articles for the *Encyclopédie*, which attained great celebrity. Of these the principal are, Etymology, Existence, Expansibility, Fair, and Foundation. He had prepared several others, but the persecution against the *Encyclopédie* induced him to decline further contributions.

In 1761 Turgot was appointed intendant of Limoges, where he gave activity to the society of agriculture; opened a mode of public instruction for female professors of midwifery; procured for the people the attendance of able physicians during the raging of epidemic diseases; established houses of industry, supported by charity (the only species of alms-giving which does not encourage idleness); introduced the cultivation of potatoes into his province, &c. &c. While he proceeded with unremitting activity and zeal in promoting the good of the people over whom he was placed, he meditated projects of a more extensive nature, such as an equal distribution of the taxes, the construction of the roads, the regulation of the militia, the prevention of a scarcity of provision, and the protection of commerce.

On the death of Louis XV. the public voice called Turgot to the first offices of government, as a man who united the experience resulting from habits of business to all the improvements which study can procure. After being only a short time at the head of the marine department, he was, August 24, 1774, appointed comptroller-general of the finances. During his discharge of this important office, the operations which he carried on are astonishing. He suppressed twenty-three kinds of duties on necessary occupations, useful contracts, or merited compensations. He abolished the corvee, or the labour required from the public for the highways, saving the nation thirty millions of livres annually. He set aside another kind of corvée, which respected the carriage of military stores and baggage. He abated the rigour in the administration of indirect impositions, to the great profit of the contributors, the king, and the financiers; besides effecting many other essential improvements in political economy. At length, however, by the artifices of the courtiers, he was deprived of his offices; and in retirement he devoted himself to the studies which he had cultivated in his youth. He died on the 20th of March 1781. An edition of his works, in 9 vols. 8vo, was commenced in 1808 and completed in 1811. He composed, it is said, the celebrated Latin inscription intended for a picture of Dr Franklin.

Eripuit cœlo fulmen, mox sceptra tyrannis.

TURIN, one of the continental provinces of the kingdom of Sardinia, in the ancient division of Piedmont. It is bounded on the north-east by Ivrea, on the east by Asti, on the south by Saluzzo, on the south-west by Penerolo, and on the north-west by Savoy, and it extends over 3209 square miles. A promontory of the Cotta Alps terminates a ridge of mountains on the north-west, the highest point of which on the border of Savoy is the Rochemalon. The rest of the province consists of gentle hills, small valleys, and some extensive plains, and a soil for the most part of high fertility. Its waters flow to the sea through the Po, which on its right bank receives the rivers Melevere and Bonna, and on its left the Clusone, the Eisola, the Dora-Riparia, the Stura, the Orco, and the Dora-Baltea. In the north-west division are some extensive woods, and in the mountains mines of iron and of vitriol, and quarries of marble and limestone. It is a country of good pasturage, and the fields produce abundant crops of wheat, maize, barley, and beans. The vineyards yield much wine, and the mulberry trees feed a vast number of silk-worms. It is a manufacturing district, making linen, silk, and cotton goods, hats, hosiery, chocolate, brandy, liqueurs, paper, pottery, china, glass, and some curious kinds of work in wood and in ivory. These articles form the basis of its trade with the surrounding countries, and furnish exports from the maritime towns to foreign kingdoms. The province contains twelve cities, fifty-four market-towns, and 347 villages; and in 1833 the inhabitants amounted to 808,526.

The capital is the city of the same name, which is also that of the whole kingdom. Turin is the residence of the monarch, the seat of the central boards of the government, and the see of an archbishop. It stands on a point of land formed at the junction of the river Dora-Riparia with the Po. It is surrounded with walls and deep ditches, and protected by fifty bastions and many outworks; and has a citadel on the south-west side, furnished with ravines, a regular pentagon, and said to be one of the strongest fortresses in Europe. The city is divided into the new and old town, has level and straight streets crossing each other at right angles, with eleven plazas or squares, and, as far as regards the exterior, with many magnificent buildings. The most striking public edifices are the royal palace in the Piazzo di Castello, the old palace, that of Aosta and of Carignan, the Collegio di Nobili, and the council-house. Among the private edifices are more than thirty called palaces, belonging to the nobility. There is a fine Gothic cathedral, and forty-seven other churches, with sixty-seven chapels and many monasteries and nunneries. Among several hospitals, the most remarkable is the Carita, which is capable of receiving 2500 patients. The university, founded in 1405, and renovated in 1630, is a fine building, furnished with various museums, and a library of 60,000 volumes. For the enjoyment of the inhabitants, Turin has four theatres, a Corso, the public gardens of the palace, the walks on the Po called the Rondeau, and some others on the glacis, as well as the parade for carriages, called the Carettino. There are some manufactures carried on, the most extensive of which is that of silk, including velvets, damasks, and ribbons. Some coarse woollen goods are made, and some small establishments prepare leather, chocolate, rosoglio, snuff, paper, china, and curious works in wax, wood, and ivory. The city with its suburbs contains 22,100 inhabitants, many of them far from affluent. Long. . 29. 25. E. Lat. 45. 4. 14. N.

TURINSK, a town of Tobolsk, in Asiatic Russia, and he capital of a district of the same name, situated along the anks of the river Tura. It was built about the year 1660, and contains 4000 inhabitants, with six churches and a convent. There is a separate suburb for the Tartars. Long. 98. 40. E. Lat. 57. 56. N.

TURIVICARY, a town of Hindustan, in the Mysore territories, forty-seven miles north from Seringapatam. It consists of an outer and an inner fort, strongly defended by a ditch and mud-wall, with a suburb at a little distance containing above 700 houses. It possesses two very ancient temples. Long. 76. 50. E. Lat. 13. 7. N.

TURKEY.

Turk or Toork is the generic name of a great family f nations which has been settled for time immemorial in Vestern Asia and the adjoining portions of Europe, and f which a branch has been for several centuries in posseson of the countries around the eastern shores of the Meterranean Sea, which, on that account, have received om Europeans the name of Turkey. The Turks have enerally been considered to be members of the Caucaan variety of mankind; but learned orientalists have now icceeded, by the aid of the Chinese annals, in identifying iem with the Hiong-nu, a people who lived to the northest of China many centuries before the Christian era, and rried on frequent and sanguinary wars with the celestial npire. From that region their migrations can be traced estward, till they finally settled in those parts of Asia and urope in which they are now found. The Osmanlee or ttoman Turks, who live in Turkey, and their brethren the Tartars of Casan, Astrakhan, and Crimea, have indeed some the physical characteristics of Caucasians; but the Nois, Kirghiz, Turcomans, and others farther east, who speak ire Turkish dialects, have a different organization, aproaching nearly to the Mongolian character It has therere been inferred, that the Turks originally belonged the Mongolian tribes; and that the portion of them w possessing Caucasian features must have acquired them intermixture with the Caucasian races, whom they inded and subdued.

The existing Turkish empire dates only from the end of e thirteenth century, when it was founded by Osman or thman, a Turk of a noble family, who had been driven estward from Khorasan by the invasion of Zengis Khan. sman first invaded the Greek territory of Nicomedia on e 27th of July 1299; but the true era of the empire ly be dated from the conquest of the city of Prusa, the pital of Bithynia, which surrendered to his son Orchan in 26. This Orchan was a restless, ambitious, cruel prince, io greatly extended the limits of the empire, took possion of Gallipoli, and penetrated into Thrace. Amuh I., his son, subdued without resistance the whole of race from the Hellespont to Mount Hæmus, and made drianople the seat of a viceroyalty. He established in 62 the famous military bands called *yengi cheri*, new diers (corrupted into janizaries), once the shield and bulrk of the empire, but in later times the cause of numbers revolts and revolutions. These troops were composed ginally of young Christian captives that had been taken war and educated in the Mahommedan religion. They re trained to warlike exercises, and inured to obedience severe discipline; and as every sentiment which ensiasm can inspire, and every mark of honour which the our of the prince could confer, were employed to aniite them with martial ardour, and excite in them a sense their own importance, these janizaries soon became the ief strength and pride of the Ottoman armies.

On the assassination of Amurath in 1389, he was succeed by his son Bajazet, surnamed Ilderim, or the Thunderlt, whose reign forms one of the most splendid epochs in the Turkish annals. He subdued and stripped of their hereditary possessions the Seljukian emirs of Asia Minor, whose revolts and disturbances had embarrassed the progress of his predecessors, and protracted the downfall of the Greek empire. His conquests in Europe were equally rapid and important, and whatever adhered to the Greek empire in Thrace, Macedonia, and Thessaly, acknowledged his sway. He turned his arms against Sigismond king of Hungary, and in 1396 defeated, in the battle of Nicopolis, a confederate army of a hundred thousand Christians, the greater part of whom were slain or driven into the Danube. The ferocious conqueror commanded his prisoners to be massacred in cold blood, with the exception of a few of the chief nobles, who were set at liberty on the payment of a ransom of 200,000 ducats. But Bajazet had now reached the height of his greatness. His conquests in Armenia and on the banks of the Euphrates had brought him into collision with the famous Mogul conqueror Tamerlane; and in 1402 the plains around the city of Angora were the scene of the memorable battle which ended in the captivity of Bajazet, and the temporary humiliation of the Turks. The death of Tamerlane, and the contentions which arose among his sons, relieved the Turkish provinces from the Mogul yoke. Solyman the son of Bajazet obtained the European dominions of his father, Mousa reigned over the remnant of his dominions in Asia, while Mohammed, the youngest of the sons, held Cappadocia. Eleven years elapsed in the mutual endeavours of the sons of Bajazet to supplant each other, before Mohammed effected his final triumph, and assumed the title of sultan. At his death in 1421 he bequeathed an undivided empire to his successor, Amurath II. The reign of this sultan contributed greatly to increase the splendour of the Turkish empire. He made himself master of Adrianople, by which Romania and Anatolia were again united under one sceptre; and reduced to subjection Servia, Macedonia, Thessaly, Albania, and the whole of Greece to the north of the isthmus. He also besieged Constantinople, but was diverted from his enterprise by the dexterity of the Greek emperor, who stirred up against him a competitor for the throne, assuming the name and character of Mustafa, the eldest son of Bajazet. But the impostor was at length defeated and put to death. The conquests of Amurath received a considerable check from the skill and valour of Hunniades, the celebrated waiwode of Transylvania, and of the Albanian chief George Castriot, whom the Turks call Scanderbeg; but the fatal battle of Varna, in which Ladislaus king of Hungary and 10,000 Christians were slain, destroyed the hopes that were entertained of checking the progress of the Turkish arms. Amurath twice abdicated the throne, and twice was compelled by the exigencies of the empire to resume the sovereignty. He was succeeded in 1451 by Mohammed II., the conqueror of Constantinople. (For a full account of this memorable siege we must refer to the article Constantinopolitan History.) On the 6th of April 1453, the standard of the prophet was planted before the gate of St Romanus; and after a siege of fifty-three days, "that Constantinople which had defied the power of Chosroes, the Chagan, and the khalifs, was irretrievably subdued by the arms of Mohammed the Second. Her empire only had been subverted by the Latins; her religion was trampled in the dust by the Moslem conquerors." Constantinople was taken by the Turks on the 29th of May 1453, two thousand and five years after the foundation of Rome, and eleven hundred and twenty-three after Constantine had removed the seat of the empire from Rome to Byzantium.

Three years after the taking of Constantinople, Mohammed laid siege to Belgrade, from which, after an obstinate resistance, he was at length repulsed with the loss of his large ordnance and forty thousand of his best troops. Abandoning his attempt upon Hungary, the sultan undertook an expedition into Greece, and about the year 1460 succeeded in subduing the whole of the Morea. In 1466 the famous Scanderbeg, who for twenty-three years had resisted all the power of the Ottoman empire, was finally compelled to take refuge at Lyssa, in the Venetian states, where he died. Mohammed had now extended his sway over the whole of Asia on this side of Mount Taurus, and over all the provinces in Europe which had formerly belonged to the eastern division of the Roman empire. Not satisfied with these conquests, he had despatched his most able general, Achmet Pasha, to invade Italy; and the capture of the strong city of Otranto had laid open that country to him, and spread universal consternation, when the danger was averted by the death of the sultan in the fifty-first year of his age, A. D. 1481. Mohammed was succeeded by his son Bajazet II., whose claims to the vacant throne were however disputed by his brother Djem or Zisimes.[1] But the claims of Bajazet were supported by the janizaries; and his competitor, after various unsuccessful struggles, was compelled to seek shelter in Italy, where he was assassinated at the instigation of Bajazet. The infamy of the deed is ascribed to Pope Alexander VI., who is said to have received 300,000 ducats for his reward. Bajazet, after a reign of thirty years, intimated his intention to resign the crown to his son Achmet; but his youngest son Selim, having secured the assistance of the janizaries, compelled his father to abdicate, and then put him to death. Selim was a successful prince, and during his short reign of nine years conquered Egypt, Aleppo, Antioch, Tripoli, Damascus, and Gaza, and defeated the Persians. On the death of Selim, Solyman surnamed the Magnificent, one of the most accomplished, enterprising, and warlike of the Turkish princes, ascended the Ottoman throne. Having quelled some insurrections in Asia, he commenced hostilities against the European princes, and entering Hungary, made himself master of Belgrade, then reckoned the chief barrier of that kingdom against the Turkish power. He next turned his victorious arms against the island of Rhodes, then the seat of the knights of St John of Jerusalem. After incredible efforts of valour and military skill, the knights obtained an honourable capitulation, and retired to the small island of Malta. Solyman next advanced into Hungary and at the battle of Mohacz (A. D. 1526) defeated and slew the Hungarian monarch, with 20,000 of his men, and took possession of the capital and the chief fortresses. Three years later he formed the siege of Vienna, but was compelled to retreat with the loss of 80,000 of his soldiers. In 1541 he again invaded Hungary, and taking advantage of a civil contest between two rival claimants of the vacant throne, he annexed the disputed kingdom to the Ottoman empire. He entered into a destructive war against Persia, and eventually succeeded in obtaining a considerable increase of territory between the Araxes and the Tigris. During the reign of this prince, the political and military administration of the Ottoman empire reached its highest state of perfection; and the arts and sciences, literature, and commerce flourished under his enlightened and munificent policy. His dominions extended from Algiers to the river Euphrates, and from the farther end of the Black Sea to the extremity of Greece and Epirus. The latter years of his reign were imbittered by domestic dissensions and cruelties. During the siege of Sigeth, a city of Hungary, before which the Turks lost 30,000 men, Solyman expired, in the seventy-fourth year of his age and forty-first of his reign.

His son and successor, Selim II., besieged and took Cyprus; but in the famous sea-fight at Lepanto, in 1571, the Turkish fleet was utterly destroyed by Don John of Austria. Selim afterwards invested and took Tunis by storm, putting the garrison to the sword. On his death, Amurath III. ascended the Ottoman throne, and extended his dominions on both sides by the addition of Tigris in Persia, and of Raab, one of the strongest fortresses in Lower Hungary. His son, Mohammed III., has no claim to notice, except on account of his barbarity. He began his reign by strangling nineteen of his brothers, and ordering twelve of his father's wives whom he suspected to be pregnant to be drowned. The war with Hungary was carried on throughout the whole of his reign, which lasted about nine years. During the inglorious sway of his son Achmet I., the affairs of Turkey underwent a material change for the worse. Peace was concluded with Hungary; but the sultan was involved in a disastrous war with Persia, in which the Turkish troops were entirely defeated. On his death, his brother Mustapha ascended the throne; but his actions having clearly proved his incapacity and imbecility, the janizaries and the divan compelled him to resign the government after a reign of five months, and threw him into prison. His nephew, Osman, the son of Achmet, a boy of twelve years of age, was then proclaimed emperor. This prince having formed the design of curbing the power of the janizaries, these turbulent soldiers rose in insurrection, deposed and murdered the sultan, and recalled his uncle Mustapha from his prison to the imperial throne. These atrocious proceedings, however, excited general indignation throughout the Asiatic provinces; and Abasa, the powerful pasha of Erzerum, took up arms to avenge the murder of Osman. After the lapse of a few months, the janizaries themselves abandoned the cause of Mustapha, who was again deposed, and was soon afterwards strangled. Under Amurath or Morad IV., surnamed Gasi, the Intrepid, affairs assumed a new appearance, and the glory of the Ottoman empire was in some measure restored. He put to death great numbers of the janizaries, and by his energetic and ferocious measures reduced these mutinous and formidable troops to a state of subordination. He took Bagdad from the Persians, and massacred the greater part of the inhabitants, after an obstinate resistance, which cost him the flower of his army. A debauch of wine put an end to his life, in the thirty-first year of his age and the seventeenth of his reign. His brother Ibrahim, who succeeded him, was a weak and imbecile prince, deformed in body, and destitute of courage. The administration of the government was wholly in the hands of the vizir Mustapha and the sultana Valide, the widow of Achmet I.; while Ibrahim gave himself up entirely to the prosecution of his pleasures, till at length his vices rendered him so odious that he was deposed and strangled. During his reign, a bloody war broke out between the Turks and the Venetians, which, after being carried on with great fury for the space of twenty-four years, ended in the extinction of the Venetian power in the Egean Sea. The alleged ground of quarrel was the reception into a Venetian port of six Maltese galɛys which had captured an Ottoman ship of war. The di- an used various pretences to allay the suspicions of the 'enetians, and throw them off their guard, till, in May 643, the Turkish fleet set sail for the important island of 'andia, and disembarked an army of 70,000 men on the land. As the Venetians had provided no means for its efence, the whole island, with the exception of the capital, as, after a sanguinary resistance, reduced in less than two ears. Mohammed IV., the son of Ibrahim, was scarcely even years of age at the deposition of his father. His mi- ority was one continued scene of intestine discord and evolt. During this reign, war again broke out between e Austrians and Turks, and after having been carried on r some time with varied success, was concluded by a eaty for twenty years. On the termination of this war, e power of the Ottoman empire was directed against the ty of Candia. The siege was actively carried on during e space of twenty-nine months, when the garrison was length forced to capitulate; and thus ended one of the ost memorable sieges of modern history, in which the Ve- etians lost above 30,000 men, and the Turks more than 20,000. About this period, the Zaporagian Cossacks threw f the Polish yoke, and placed themselves under the pro- ction of Turkey. A war in consequence broke out be- 'een the Turks and the Poles; but the result was advan- geous to the Porte, who obtained the sovereignty of the portant districts of the Ukraine and Podolia. Shortly ter, however, the Hetman of the Cossacks having been eated with contempt by the sultan, these proud and fickle rbarians abjured the Turkish service, and transferred eir allegiance to the Russian czar.

---

[1] Historians differ in opinion as to the pretensions of these princes. Some affirm that Djem was the eldest son, others that he claimed the crown because he was the son of a sultan, whereas Bajazet was born before his father ascended the throne.

In 1683 the distracted state of Hungary induced the van to break the treaty with Austria; and the Turkish my, under the grand vizir Cara Mustapha, penetrated Vienna, and formed the siege of that city on the 14th of ly. The siege was protracted till the 12th of Septem- er, when the allied army, under the famous John Sobieski, tacked the besiegers, routed them with prodigious slaugh- r, and obtained possession of their camp, together with eir artillery, baggage, and magazines. A succession of ttles followed, in all of which the Turks were overthrown. he number of their enemies speedily augmented, and in e short space of four years all the vast conquests of the urkish sultans, westward of the Danube, were wrested om them, with the solitary exception of the fortified city Agram. These extraordinary reverses caused the army revolt against their commanders, and excited a general surrection, which cost the sultan his throne. His brother, lyman II., who succeeded him in 1687, was distinguished r his austerity, sobriety, and devotion. He was happy in s domestic government, but unsuccessful in his wars. He as succeeded in 1690 by Achmet II., the youngest son of ltan Ibrahim. He too was a weak and credulous prince; d though the affairs of the empire were conducted with eat prudence and vigour by the grand vizir Kiuperli, e Ottoman empire declined, and the Turks during this ign were driven out of Hungary and Transylvania. The cession of his nephew Mustapha II. to the Ottoman rone gave a new turn to the affairs of the Porte. Pos- ssed of greater vigour and ability than his predecessor, he solved to command his troops in person. He accordingly ok the field, passed the Danube at the head of 50,000 en, carried Lippa by assault, and, falling suddenly on a dy of Imperialists under Veterani, one of the bravest and st officers of the emperor, he defeated them, and closed e campaign with success. But two years afterwards he as defeated by Prince Eugene, in the bloody battle of enta, a small village on the western bank of the Theiss, the kingdom of Hungary. About 20,000 Turks were ft dead on the field, and 10,000 were drowned in their tempt to escape; and the magnificent pavilion of the sultan, and all his stores, fell into the hands of Prince Eugene. These terrible disasters compelled Mustapha to solicit a peace, and a treaty was shortly after signed at Carlowitz, which guaranteed Hungary, Transylvania, and Sclavonia to the Austrians; Azoph to the Russians; Podolia, the Ukraine, and Kaminiecz to the Poles; and the Morea, with a strong frontier in Dalmatia, to the Venetians. Shortly after these misfortunes, an insurrection was excited among the soldiers by a sense of the national disgrace, and Mustapha was dethroned.

His brother and successor, Achmet III. gave an asylum to Charles XII. king of Sweden, at Bender, a Turkish town in Moldavia, after his defeat at the battle of Pultowa. (See RUSSIA and SWEDEN.) A war broke out between the Russians and the Turks, in which the czar Peter, having imprudently suffered himself to be cooped up in an angle formed by the river Pruth, was reduced to the greatest extremities, and compelled to make peace on terms dictated by the Turkish general. Being unsuccessful in his war against Kouli Khan and the Persians, Achmet was deposed, and was succeeded by Mohammed V.

From the deposition of Achmet III. in 1730, to the accession of Mustapha III. in 1754, nothing of importance occurs in the history of the Turkish empire. During the reign of this latter sultan, was begun and terminated that destructive war with Russia which broke out in 1769, and lasted till 1774, when the successes of the Russians compelled the sultan, Abdul Hamid, to terminate the unequal contest by the dishonourable treaty of Kainardghi. By this treaty Russia obtained possession of the tract between the Bog and the Dneister, known by the name of New Servia, the forts of Yenikaleh and Kertcsh in the Crimea, and the fortress of Kilburn, at the embouchure of the Dneiper, opposite to the town of Ockzakow. The Krim Tartars were declared independent, and Russian merchant-vessels were admitted to the free navigation of the Bosphorus. About this time a formidable rebellion broke out in Egypt, which was suppressed chiefly by the wise conduct and intrepid behaviour of Hassan Bey, the capitan pasha, who at the age of seventy fought with all the ardour of youth, and all the skill of the most consummate general. That veteran, however, was recalled before he was able to carry all his patriotic designs into execution, that he might aid the divan with his counsel in the critical situation into which the empire was brought by the arrogant claims of the court of Russia. The result of the deliberations was a precipitate declaration of war against that power, contrary to the better judgment of the old pasha. The war commenced in the autumn of 1787, and the hordes of Tartars which were first brought into the field were everywhere defeated by the superior discipline of the Russian troops, commanded by Prince Potemkin. Some enterprises which were undertaken by the Turks against the island of Taman and the Crimea, were attended with as little success as the attempts of the Tartars, while the emperor Joseph declared to the Porte that he would assist his ally the empress of Russia with an army of 80,000 men. Four Austrian armies were accordingly assembled, one at Carlstadt in Croatia, under the command of General de Vins; another at Peterwaradin in Hungary, commanded by General Langleis; a third on the borders of Lithuania, under General Febris; and the fourth in the Buckowine, under the orders of the Prince of Saxe-Coburg. Other two generals, ten lieutenant-generals, and thirty major-generals, were all ordered to prepare for active service in the frontier armies.

The war between the Turks and the Austrians was carried on with varied success. At first the advantage was evidently on the side of the former, and the Austrians were repulsed with disgrace in their attempt to obtain possession of Belgrade. The prince of Saxe-Coburg displayed indeed prodigies of valour; but being opposed to a superior force, he was long obliged to act only on the defensive. He was at length joined by a body of Russians under General Soltikof, and preparations were made for commencing in form the siege of Choczim, which was surrendered to the allied armies on Michaelmas day 1780, after a defence which would have done honour to the ablest general in Europe. Still, however, success seemed to lean to the side of the Turks. The grand vizir made a sudden incursion into the Bannat, and spread consternation and dismay to the very gates of Vienna. The Austrian affairs seemed approaching to a very alarming crisis. Not only the splendid views of conquest, which were beheld in the imagined partition of a tottering empire, had totally disappeared, but had left in their place the sad and gloomy reverse of a discontented and impoverished people, an exhausted treasury, and an army thinned by pestilence and desertion. In this situation of affairs, Marshal Laudohn was with some difficulty drawn from his retirement to take the command of the army in Croatia; and under his auspices fortune began to smile on the Austrian arms. He quickly reduced Dubicza and Nevi, though they were both defended with the most obstinate bravery. He then sat down before the Turkish Gradisca; but the autumn rains ensuing with such violence that the Saave overflowed its banks, he was compelled to raise the siege. During this period the war in the Bannat raged with the utmost violence. Much desperate valour was displayed on the one side, and many brave actions were performed on the other; while a great part of that fine but unfortunate country suffered all the desolation and ruin that fire and sword, under the dominion of vengeance and animosity, could inflict.

In the midst of these military operations, Selim III., the only son of the sultan Mustapha, mounted the imperial throne. The new emperor did not want either courage or prudence, and he continued the war with Russia and Austria with great spirit and resolution. Marshal Laudohn renewed his attempts upon Gradisca as soon as the season would permit, and, after a brave defence, it fell into his hands. This with some other successes roused the emperor from his state of inactivity, and made him seriously determine on the attack which he had long meditated on Belgrade. The enterprise was intrusted to Laudohn, who, with his usual good fortune, made himself master of the place in less than a month. The rest of the campaign was little else than a series of the most important successes. While one detachment of Laudohn's forces took possession of Czernitz in Wallachia, another made itself master of Cladova in Servia. Bucharest, the capital of the former of these provinces, fell without opposition into the hands of Prince Coburg, while Akerman, on the Black Sea, was reduced by the Russians, and Bender surrendered to Prince Potemkin, not without suspicion of sinister practices.

Soon after this the emperor Joseph died, and his successor Leopold showed a desire for peace. After the reduction of Orsova, therefore, which happened on the 16th of April 1790, the war was carried on with languor on the part of Austria, and in the month of June a conference was agreed on at Reichenbach, at which the ministers of Prussia, Austria, Britain, and the united provinces, assisted, and at which also an envoy from Poland was occasionally present. After a negotiation which continued till the 17th of August, it was agreed that a peace should be concluded between the Austrians and the Ottomans; and that the basis of this treaty should be a general surrender of all the conquests made by the former, retaining only Choczim as a security till the Porte should accede to the terms of the agreement, when it also was to be restored.

In the mean time the empress of Russia persevered in hostilities, and carried on the war with great vigour and success. In the campaign of 1790, the Russian general Suwaroff carried the strong fortress of Ismail by an assault, which for violence and bloodshed has no parallel in modern times. The Ottoman empire seemed on the verge of destruction, when the empress at length, induced by the darkening aspect of European affairs, concluded with the Porte a definite treaty of peace at Yassy on the 9th of January 1792. The stipulations of the treaty of Kainardghi were renewed. The river Dneister was recognised as the boundary of the two empires. Oczakow was ceded to Russia, with the territory between the Bog and the Dneister; and the cession of the Crimea, of the isle of Taman, and part of the Kuban, was again formally confirmed.

It was evidently the desire and endeavour of the Ottoman government to keep aloof from the terrible wars and changes which accompanied the French Revolution; but the invasion of Egypt by the French compelled the sultan to abandon the system of neutrality which he was anxious to maintain. (A full account of this event will be found under the article EGYPT.) On the recommencement of hostilities with France, attempts were made to induce the Porte to take part in the war against that country. "Russia and England united their strength against France in the divan, and the sultan was the sad spectator of a contest of which he was himself the unwilling umpire, the ostensible object, and the proposed prey. The victory of either party alike menaced him with ruin, he had to choose between the armies of France and the fleets of England. Never was sovereign so situated between two negotiators, one armed with the power of the land, the other with that of the sea; both to all appearance able to destroy, but neither capable of protecting him against his antagonist. The precipitate flight of the British ambassador had scarcely relieved him from the embarrassment of making a selection between the menacing parties, when his capital was alarmed for the first time by the presence of a hostile force, and the last of calamities seemed reserved for the reign of Selim.[1] The good fortune which interposed to save the seat of empire was not extended to the sovereign, and the evils which were inevitable from the triumph of either party gathered fast around him from the day that saw the city of the faithful delivered from the insults of a Christian flag."[2]

The year 1807 witnessed one of those sanguinary insurrections which have so often convulsed the Ottoman empire. The cause of this revolt, which cost Selim his throne, was an attempt to introduce the improved system of European tactics into the military and naval establishments. The sultan had evinced, at an early period of his reign, a determination to attempt some changes in the organization of the military force, and for this purpose new regulations were issued in 1796. The chief arrangement was the levy of 12,000 men, who were to be disciplined according to the principles of European tactics, and armed in every respect like British or French soldiers. The new troop were to wear a uniform, and were to be taught the manual exercise; and, in order to detach them as much as possible from the janizaries, it was resolved they should belong nominally to the corps of bostanges. For these bostange fusileers, as they were called, were erected handsome barracks three miles to the north-east of Pera, capable of containing 15,000 soldiers. For the same purpose, barracks were also constructed at Scutari, with exercising ground and all other conveniences. The inspector of the new troops was one of the principal men of the empire. A reform was introduced into all the military departments. The *topges*, or cannoniers, were improved in every respect. Their old barracks were demolished, and new ones were built on a regular and better plan. The *arabdyes*, or troops of the waggon train, were also reformed. The gunpowder manufactories, which had been in a most inefficient state, were placed on an entirely new footing. The bombardiers, anciently furnished from the ziameths and timars, or military fiefs, underwent a total change by the new regulations. The miners, a corps much neglected, were increased, and attached by the new constitution to the bombardiers. The marine was put under the superintendence of a ministry formed on the plan of European admiralties; and the command of vessels, which had usually been set up to sale, was given only to those who were qualified for the office. Dry docks, caulking basins, a harbour for fifty new gun-boats, and all the necessary appurtenances of a great arsenal, were built at the edge of the water at Ters-Hanc; and designs for similar contrivances were to be applied to the other principal harbours of the empire. In addition to the institutions for the formation of the new troops, and the improvement of the Ottoman navies, a general regulation provided that the janizaries should be regularly exercised in the use of the musket, with their *sakas* and other assistants. Magazines for victualling the armies were constructed on the Danube, and at other points near the seat of war. In order to provide for the increased disbursements of the public exchequer, a new revenue was created; and for this end a treasury was formed, under the control of a great state officer, chosen from among the chief men of the empire. Such is a brief outline of the new regulations issued by Selim; and skilful and enlightened though they were, they excited great dissatisfaction in most classes of the community. The janizaries, in particular, foresaw in the formation of the new troops the extinction of their own influence, and therefore determined upon revolt. Their discontent was privately fomented by Mousa Pasha, the kaimacam, a cruel and ambitious character, who entertained the most deadly hatred against the superior officers of the divan, and had long resolved to excite a revolution for the purpose of destroying them. The first symptoms of insurrection manifested itself among the troops belonging to the garrisons of the Dardanelles. A certain number of adventurers, under the name of yamaks, or assistants to the batteries, had shortly before been added to the nizam-jedid, for the service of the batteries of the Bosphorus. They carried the same arms as the nizam-jedid, and were trained to the same discipline. It was at length resolved to incorporate them with the other troops; and accordingly, on the 25th of May 1807, an order was issued for clothing them in the new uniform. The yamaks immediately rose in open mutiny, and put to death the reis-effendi, who had brought the commands of the sultan. Hali Aga, the commandant of the batteries on the Asiatic shore, was murdered on the same day, and his corpse was also thrown into the Bosphorus. On the next morning, the yamaks, to the number of three thousand, having assembled in the plains of Buyukdere, elected a chief, and marched directly to the capital. At this juncture the kaimacam intimated to the several ortas of janizaries that the time was come for overturning the new institutions; and accordingly, on the 27th they rose, and, as the signal of insurrection, carried their camp-kettles to the well-known place called Etmeidan, an open square near the aqueduct of Valens, which has been from time immemorial the camp of the insurgents. "The sultan," says Sir John Hobhouse, "was now awakened to a sense of his danger; he assembled his ministers at the seraglio, and the 28th of the month was passed in negotiation with the insurgents in the Etmeidan. During the day the fate of Selim was on the balance; he transmitted to the Etmeidan an offer to abolish the new institutions, to which the janizaries returned no other answer than a demand for the immediate execution of all the ministers who had advised and presided over the nizam-jedid. Then it was that the kaimacam insidiously assured him that the sacrifice was necessary, and would appease the rebels. All was not yet lost. If at that moment the gates of the seraglio had been shut, a cannon had been fired, and the head of Mousa Pasha himself had been struck off and thrown over the walls, Selim would have triumphed and retained the throne of his ancestors. But the instant peril and the presence of his enemies bewildered the faculties and so absorbed the resolution of the sultan, that he seems to have despaired of resistance, and to have placed all hopes of safety in submission alone. It was not suggested to his mind, that with the new troops of Scutari and Tchiftlik, and other soldiers in the vicinity of the capital, he might speedily assemble 30,000 men, not less devoted to himself than inimical to the janizaries; and that until their arrival he could maintain the seraglio against the rebels, by arraying the forces of his numerous bodyguard. Yet the testimony of all the reports prevalent at this day in Constantinople concurs in the persuasion that such an opposition, with the instant death of the kaimacam, would have dismayed the insurgents and crushed the rebellion. But the traitor prevailed, and with a cruel ingenuity contrived to include in the prescription the names of two old and innocent men, the kehayah-bey and the reis-effendi, who were called to a conference with Mousa, and, on leaving the room unsuspicious of their danger, were carried away to the second gate and strangled. The number of heads presented to the janizaries early on the morning of the 29th was seven; but the ruffians, rising in their insolence, were not satisfied with the bloody offering, and, on recognising the aged victims of the resentment of Mousa, declared that they had required another sacrifice. 'The heads were not those of the enemies whose punishment they had demanded.' The sultan hearing this last intelligence, sent for the mufti, and on learning that he withheld his advice, found that he had ceased to reign.

---

[1] About three weeks after the departure of the British ambassador from Constantinople, Admiral Duckworth, with eight sail of the line, two frigates, and two bomb-vessels, passed through the straits of the Dardanelles, and advanced within two leagues of Cape St Stefano. But a sudden calm having rendered the English fleet stationary, the fortifications of the capital were so strengthened that it was soon rendered perfectly free from danger, and the British admiral was under the necessity of hastening from the Propontis before his return was rendered impracticable.

Hobbouse's Letters on Albania.

"The janizaries, headed by the traitor Mousa, had already found their way into the seraglio, when the sultan retired to the mosck of the palace, and wrapping himself in the robe of Mahomet, took his seat in the corner of the sanctuary. Here he was found by the mufti, who entreated him to submit to the wishes of the people, and to resign the crown. Another report says that, previously to this moment, he had told his attendants that he would reign no more, and ordered them to bring his successor before him. The circumstances of this actual deposition were not exactly known; but on the evening of the same day (the 29th) it was understood in all the quarters of the capital that the most injured, if not the best, of the Ottomans had stepped from a throne to a prison, and that the reigning monarch was his cousin, Mustapha the Fourth, eldest son of Sultan Abdulhamid." This prince was thirty years old when he was placed on the throne. Of a feeble character and limited attainments, he became a mere instrument in the hands of others, and was the servant rather than the master of the armed multitude to whom he was indebted for his elevation. The supreme power was in the hands of the janizaries, the new institutions were abolished, the new troops dispersed, and their principal officers executed. Their triumph, however, was but of short duration, and the punishment which they so justly deserved was speedily inflicted. Mustapha Bairactar, the pasha of Rudshuk, owed his elevation to the personal regard of the

History.

dethroned sultan, and determined to avenge his fall. So early as October 1807, he formally intimated to the sultan, that he should advance to the capital to reform the abuses of the state, and to assist him in the administration of public affairs. Accordingly, having collected an army of forty thousand men, he marched to Constantinople, and encamped on the plains of Daout Pasha, four miles from the city. There his camp soon became the centre of the business and affairs of the Porte, whose chief officers directed their visits of ceremony to the tent of the triumphant general. But the pasha, conscious that his authority in such a state of affairs was unstable, resolved upon the restoration of the sultan Selim. The 28th of July 1808 was fixed upon for the enterprise; and as Mustapha had appointed that day for a hunting expedition, Bairactar determined to enter the palace during his absence, and, by preventing his return, exclude him from the throne. Unfortunately the secret transpired; and when, at the appointed time, Bairactar marched to the seraglio, he found the gates closed, and the body-guard under arms. Orders were given for an immediate assault; and after a brief contest, the insurgents forced their way into the seraglio. But the interval proved fatal to Selim. At the commencement of the contest, the emissaries of Mustapha were despatched to his apartments, and after a powerful resistance, that ill-fated prince was thrown down and strangled. After the murder of Selim, the strictest search was made for Mahmoud, the youngest son of Abdulhamid, and the only remaining prince of the blood-royal. But a faithful slave had concealed him in the furnace of a bath, and before the place of his concealment could be discovered, the insurgents had forced their way into the interior of the palace. Advancing to the third gate, they called aloud for the instant appearance of Selim, when the eunuchs of Mustapha, casting the body of the murdered monarch before them, exclaimed, "Behold the sultan whom you seek!" Bairactar, overpowered by his feelings, threw himself on the disfigured corpse, and wept aloud; till Seid Ali, the capitan pasha, exhorting him to seize the moment for revenge, he instantly aroused himself, and commanded that the Sultan Mahmoud should be proclaimed, and Mustapha arrested. The command was immediately obeyed; Mustapha was consigned to the prison of the seraglio, and Mahmoud was released from his painful concealment, and placed on the Ottoman throne. On the ascension of Mahmoud, Bairactar was of course made grand vizir; and he avenged with unsparing severity the death of his benefactor. The traitor Mousa Pasha lost his head, and all the officers of the yamaks and the most seditious of the janizaries were strangled and cast into the Bosphorus; and the females of the harem who had rejoiced at the death of Selim were sewed up in sacks and precipitated into the sea near the shores of Prince's Island.

The vizir openly avowed his intention of reforming the system of the janizaries, and retrenching their privileges; and it was resolved to revive the order of the Seimens, who might supply their place, and be regulated according to the discipline of the nizam-jedid. The name of this corps was more odious to the janizaries than even that of Selim, as belonging to an institution more ancient than their own; and they were only the more resolved to ruin the author of the innovation. Bairactar, however, becoming elated by prosperity, began to despise their enmity; and, blinded to the danger by which he was surrounded, came to the fatal resolution of dismissing the greater part of the provincial troops, and thus remained almost unprotected in the midst of an infuriated soldiery thirsting for his destruction. On the night of the 14th of November, several thousands of janizaries, issuing from their quarters, surrounded the palace of Bairactar, and set fire to the building. The vizir and his friends escaped from the conflagration into a strong stone tower, used as a powder magazine, which the janizaries attacked in vain. But in the middle of the night the whole city was shaken by a tremendous explosion; and it was found that the magazine, with the grand vizir, had been blown into the air, whether by accident or design is to this day unknown. During the two following days the contest raged with unabated fury, till the forces of the arsenal and of Tophana united themselves to the janizaries; and the death of Bairactar becoming known, the Seimens withdrew from the combat. In the mean time, the officers of Mahmoud had strangled the imprisoned Mustapha; and the sultan having no longer any thing to fear from the partiality of the janizaries for his predecessor, commanded the cannonading to cease, and at the same time announced to the janizaries that the Seimens were abolished for ever. The friends of the late vizir saved themselves by embarking on board a vessel at the Seraglio Point; but the victorious janizaries completed their vengeance by the destruction of the magnificent barracks of Sultan Selim at Scutari and Tchiftlik, at the latter of which, five hundred Seimens defended themselves with desperate valour against a multitude of assailants, until their quarters were fired, and they all perished in the flames. Thus terminated the most tremendous revolution that Constantinople had experienced since it fell under the power of the Turks, and which, after dethroning two monarchs and spilling the best blood of the empire, ended in the destruction of the meditated reforms, and the entire re-establishment of the ancient institutions.

During these events, the war with Russia had languished; but on the accession of Mahmoud, the armies on both sides were augmented, and the contest was carried on with great ferocity. The campaign of 1811 was short, but disastrous to the Porte, the main body of the Ottoman army having surrendered as prisoners of war. The result might have been fatal to the Turkish empire; but in 1812 the prospect of the arduous struggle with France induced Russia to make peace with the Porte, on the latter ceding Bessarabia and part of Moldavia. At the peace of Tilsit, Napoleon left the Turkish empire single-handed to fight or fall, though it had been induced to take up arms solely by French promises and intrigue. The neglect was deeply felt by the Ottomans, and it received its just punishment when the unexpected pacification of 1812 released the Russian army just in time to interrupt the distressed French troops in their attempt to pass the Beresina. The sultan being now happily freed from foreign enemies, resolutely entered on the difficult task of reducing to obedience the great officers of his empire, who during the distracted state of the country had virtually exercised independent power; and in the course of a few years, the famous Ali Pasha and the other powerful and rebellious satraps were all deprived of their governments, and most of them executed. In 1821 began that celebrated insurrection which, after a bloody war of eight years, terminated in the complete emancipation of the Greeks from the Turkish yoke. (See GREECE.) Meanwhile the tranquillity of the empire was again threatened by the janizaries. They had chosen to take umbrage at certain members of the divan; and, in consequence of their representations, in November 1822 four of the obnoxious ministers were exiled, and Halet Effendi, the keeper of the signet, was put to death. This interference, however, is supposed to have been the remote cause of the destruction of these troops. The necessity of introducing new systems of discipline had long been apparent to every thinking man, and the government was anxious to do so; but every attempt had hitherto proved fatal to the innovator. The sultan resolved to make another effort, and if the janizaries resisted, to extirpate them altogether. In conformity with these designs, one hundred and fifty men were selected from each orta of the janizaries, who were instruct-ory.

d in European tactics by Egyptian officers. As it was de-lared that this was merely a revival of an exercise used by olyman, matters proceeded quietly for some time, till, in June 823, when the troops were brought together to exercise, ey discovered for the first time that they were practising e very evolutions which they had all determined to resist. furious insurrection immediately took place, the palace of e Porte was pillaged and stripped, and the insurgents, to e number of twenty thousand men, assembled in the well-own Etmeidan. The sultan perceived that the crisis hich he had both expected and feared had now arrived, d he determined at once to put an end to a domination hich had been found so intolerable. He directed the sa-ed standard of the prophet to be raised, and the zealous ussulmans rushed from all quarters to range themselves der it. He issued orders to the pasha aga, and to the ogee hashi or commander of artillery, to hold themselves readiness with their troops. Before, however, proceed-to extremities, four officers of rank were despatched the Etmeidan, with offers of pardon if the insurgents uld immediately disperse; but the offers were scorn-ly rejected, and the officers were wantonly put to death. e aga pasha had by this time collected about 60,000 n; and surrounding the Etmeidan, where the janizaries re assembled in a dense crowd, totally unsuspicious of sultan's intention, he opened upon them a general dis-arge of grape-shot, which killed vast numbers. The survi-s retired to the barracks, which were close by, and there it themselves up. But orders were immediately given to fire to the buildings. The artillery thundered upon the lls; and after a desperate resistance, in which they slew reat number of the assailants, the janizaries were utterly erminated. For two days afterwards, the gates of the continued closed, and strict search was made for such the janizaries as might have escaped the slaughter in the neidan, and these, when found, were immediately exe-ed. About twenty thousand were put to death in the ital alone, besides the numbers which perished in the vinces. Thus, after four centuries and a half, this for-lable and capricious corps, once the great bulwark of empire, but eventually the pest and disturber of the mmunity, and an insuperable barrier to all improvement, totally destroyed, and the imperial throne freed from intolerable yoke.

n 1828 war again broke out between Turkey and Russia. e first campaign was unfavourable to Turkey, but not pletely decisive. In 1829, however, the Russian ge-al Diebitsch succeeded in passing the formidable barrier he Balkans; and the war being closed in September by peace of Adrianople, Turkey consented to several ar-es both humiliating and injurious.

hortly after occurred that rupture between the sultan Mehemmed Ali, the pasha of Egypt, which shook the oman empire to its foundations. In every conflict the kish troops were completely overthrown. The battle Homs decided the fate of Syria, and the victory at iich placed the sceptre almost within the grasp of the itious pasha. In this extremity the sultan was reduced he humiliating necessity of applying for aid to Russia; , through the intervention of that power, peace was con-led, and the whole of Syria, with its dependent terri-es, rewarded the successful rebellion of Mehemmed Ali.

n 1839, the sultan and his powerful subject again came collision; and the Turkish army, under the seraskier iz Pasha, crossed the Euphrates, but was completely ed by Ibrahim Pasha at Nezib, near Aleppo, and the p, artillery, and baggage, fell into the hands of the ptians. This disaster was followed by the loss of the kish fleet, which the capitan pasha carried to Alex-ia, and delivered up to Mehemmed Ali. The sultan, had long been diseased, survived this engagement only three days, and was succeeded by Abdul Medjid, a youth of nineteen years of age. The young sultan was taken under the protection of the five great European powers; and on the 15th of July 1840, a treaty was concluded by Britain, Austria, Russia, and Prussia, for the settlement of the eastern question, France having refused to become a party to it. By the terms of this agreement, Mehemmed was offered the hereditary government of Egypt and of the pachalik of Acre. Having however refused to comply with the terms, he has been excommunicated, and his forfeiture proclaimed by the sultan and the ulema; and the fleets of the allied powers have proceeded to reduce the fortified places on the coast of Syria. They have already obtained possession of Beyrout, Saide, and St Jean d'Acre; the last of which was evacuated by the Egyptian troops after a bombardment of only three hours' duration, on the 3d of November 1840, though it had cost Ibrahim a siege of seven months to reduce it in 1832, and though he had subsequently made it one of the strongest fortresses in the world. (B. Q.)

Statistics.

STATISTICS.

The Turkish empire extends continuously into the three quarters of the old world, occupying the contiguous south-eastern corner of Europe, the south-western corner of Asia, and the north-eastern corner of Africa; between 20° and 48° north latitude, and 16° and 48° east longitude. Its greatest extent is in the direction of the meridian, measuring 1680 geographical miles from north to south, and 1570 from east to west; but its area by no means corresponds to a square of that extent, for its form is most irregular, and its outline is deeply indented by seas and deserts. There is accordingly great variety in the estimates which have been formed by geographers of its superficial contents. Malte Brun states it at 815,196 square miles; but, including all its appendages, it may be stated in round numbers at little less than 1,000,000 square miles, of which one sixth is in Europe, three sixths or one half in Asia, and the remainder in Africa. The empire is naturally divided into three very distinct portions, the European, the Asiatic, and the African; and these we shall describe separately.

Turkey in Europe.

In its present reduced dimensions, excluding Greece and the islands, but still including the dependent states of Moldavia, Wallachia, and Servia, this country has an extent of about 700 miles from east to west, between the western border of Croatia and the channel of Constantinople, or the mouths of the Danube, and of 650 from north to south, between the frontier of Greece and the northern extremity of Moldavia, including an area of nearly 180,000 square miles.

In its general aspect Turkey may be described as divided into two great portions; the one consisting of the low country between the base of the Balkan range on the south and the Carpathians on the north, extending north-eastward to the borders of Russia, and forming the basin of the Lower Danube; and the other all the rest of the country southward to the frontier of Greece. The nucleus of the latter portion is formed by various ranges of mountains which have been considered to be only a prolongation of the Alps, or at least as connected with that range by the very hilly country which is found at the north-eastern corner of the Gulf of Venice. All the best maps, however, are crowded with false indications; not only false or ill-spelled names, but also ill-placed localities. Hills and even large rivers are totally omitted, while many parts of the maps on which hills are marked are merely imaginary representations. All the maps exhibit a central chain of great magnitude; but in

Statistics. reality the Balkans, from Sophia to the Black Sea, are in general only a range of small heights. The central part of the chain may be crossed anywhere in a day, or in some parts even in a few hours.

Mountains. The principal chains of mountains may be enumerated in the following order. 1. The Tchar (ancient *Scardus*), a high and extensive range, which forms the western part of the central chain. 2. The Despoto-dagh (ancient *Rhodope*), which begins near Dubnitza and Djumaka, and runs in an east-south-east direction, diminishing in height till it terminates rather abruptly about six leagues south-west of Adrianople. Its loftiest summits are towards the west, and reach an elevation of 8000 feet, or probably more. 3. The group of hills which occupies a large and very wild tract of country between 42° and 43° 30′ N. lat. and 19° and 21° 20′ E. long. and is but little known. 4. The chain of Pindus, which extends from Metzovo (39° 50′ N. lat.) to the north-west, beyond the lake of Ochrida, where some parts of the chain reach an elevation of 6000 or 7000 feet. Its southern extremity is connected with Olympus by a somewhat lower chain, which separates Thessaly from Macedonia. 5. The true Balkan (ancient *Hæmus*), which extends eastward from the neighbourhood of Sophia, to Emineh Burun on the Black Sea. It is a much lower chain than the Despoto-dagh; the southern slopes are generally very steep, but on the north side it is only the highest ridge which is much inclined, and on that side also the country falls by a series of parallel ridges diminishing in height towards the Danube, which flows past a series of small hills on the Bulgarian side, while on the Wallachian side the country is flat. The western part of the Balkan probably reaches an elevation of 4000 feet; but, near the sea, the summits are only from 1800 to 2000 feet above its level. 7. The preceding chains are connected by a large undulating high country or plateau, extending from east to west between Sophia and Pristina, and forming the upper part of the basin of the Morava. From this plateau ranges of mountains extend in every direction into Servia, Macedonia, Albania, and Thrace, some of which attain the elevation of 5000 or 5500 feet. 8. South of Adrianople, between the Maritza and the Dardanelles, are the low ridges and plateaus of the Tekir-dagh, which rise only to the height of about 900 feet; but to the south-east of Aimadtschik there is a somewhat higher range, which, near the Sea of Marmora, is probably 300 or 400 feet higher than the Tekir. 9. Along the south-western shore of the Black Sea, a very low chain extends from the Bosphorus to the north-west, forming the water-shed between that sea and the basin of Adrianople. It is not in immediate connection with the Balkan; while, on the other hand, towards the Bosphorus it becomes divided into a number of small hills situate on low-lying plateaus. 10. Between the lower Strymon and the lower Vardar, on the coast of Macedonia, there is a group of low hills, of which the almost insulated ridge of Athos may be considered as the south-eastern extremity. A prominent character of the orography of European Turkey is the presence of vast cavities or high plains at the foot of the mountains, and the number of extensive cross fractures in the latter. The plains may be regarded for the most part as longitudinal valleys, and some, if not all of them, appear to have been once the beds of lakes.

Lakes. Only a few lakes however now remain, as those of Ochrida, Kastoria, Joanina, and Scutari, and even these are rapidly filling up.

Rivers. The only river of any importance is the Danube, which has been already described. (See DANUBE.) It now forms the northern boundary of the territory under the immediate government of the Padishah, and is navigable for steamboats upwards from the Black Sea to the interior of Germany, excepting only at the Irongate, on the borders of Hungary, where the navigation is effectually interrupted by rapids. The navigation of the Danube being of essential importance to the commerce of the Austrian empire, and the lower part of it being not only circuitous and obstructed with shallows, but also exposed to interruption from the fiscal and sanatory regulations of the Russian government, which has got possession of the river-mouths, a convention was some years ago entered into between the Austrian and the Turkish governments, the latter of which undertook to form a canal from the Danube near Rassova, to Kustendjil on the Black Sea; but the work is not yet begun, and it has been proposed, more recently, to substitute a railway.

In a country consisting of so many high plains, and intersected by so many lofty mountains, the climate must necessarily be very various. Along the western coasts the climate partakes somewhat of that of Italy, though colder, owing to the vicinity of the mountains; but the maritime regions along the east coast are exposed to the north-east winds, which blow frequently, and bring intense cold and thick fogs and rain from the Black Sea. At Constantinople the climate is extremely changeable; the temperature will sometimes fall 31° in a single hour. Indeed it depends upon the north or the south wind, whether one is shivering in the cold of Russia, or luxuriating in the balmy air of Greece. The winters are extremely long and severe; the roads are often blocked up with snow, and the wind on the Bosphorus is often so violent, that all communication between the city and the villages far up the channel is cut off. Upper Macedonia and Thrace (the modern Rumelia) were considered by the ancients to be cold countries; and it was in the former that they placed the residence of Boreas. The country nevertheless is rich in corn and woods, and well adapted for the vine. For the climate and natural productions of the other provinces, see the articles ALBANIA, BOSNIA, BULGARIA, CROATIA, MOLDAVIA, WALLACHIA, and SERVIA.

Turkey in Asia.

This large and important part of the empire is situate between 31° and 42° N. lat. and 26° and 48° E. long. Its greatest length, measured diagonally from the mouth of the Dardanelles to the mouth of the Euphrates, exceeds 1400 miles; and its greatest breadth, from the southern border of Palestine to the north-eastern extremity of the pashalic of Akhalzik, exceeds 900. Its area may be about 500,000 square miles. It is bounded on the north by the Black Sea and a part of the Russian territory; on the south by the deserts of Arabia; on the east by Persia and Russian Armenia; and on the west by the Mediterranean Sea, the Archipelago, the Dardanelles, the sea of Marmora, and the channel of Constantinople. It consists naturally of four very distinct portions, namely, 1. the peninsula of Ana-doli or Asia Minor, situate between the Black Sea and the Levant part of the Mediterranean; 2. the high table-land of Armenia and Kurdistan to the north-east; 3. the low countries of Assyria, Babylonia, and Mesopotamia, traversed by the Euphrates and the Tigris; and, 4. Syria and Palestine, which together form the eastern shore of the Mediterranean Sea, and extend between it and the Arabian desert.

Armenia and the northern part of Kurdistan form an elevated table-land, or series of plains and valleys, some of which are 5500 feet above the level of the sea, intersected and overtopt by ranges of mountains. This is however a fertile corn country, and abounds also in pastures, though the climate is cold, and in winter the whole region is covered with deep snow. From Armenia two ranges of mountains proceed westward. One of these, the ancient Taurus, runs parallel to the shore of the Mediterranean Sea, and then dividing into a number of branches, which intersect the western part of the peninsula, forms as many fertile valleys watered by fine rivers, and terminates on the shores or in the islands of the Archipelago. The other chain, Anti-Taurus, extends in a south-westerly direction

Statistics.

into the interior of the peninsula, where it is probably connected, not only with the ranges of Taurus, but also with the lofty mountains which under various names occupy the country between the Kizil-Irmak and the Sea of Marmora. The central part of the peninsula, supported on all sides by these mountains, forms a series of elevated table-lands, nearly destitute of trees, but abounding with pasturage. Some of its valleys are so completely surrounded by mountains, as to have no outlet for their waters, which not only overflow large tracts of country in the rainy season, but also form a number of permanent lakes, some of which are intensely salt, as those of Van and Koch-hissar. The climate of this upland region is so severe that no plants are to be seen but such as are found in the Highlands of Scotland. The summer is of very short duration, and the low country along the coasts is so much affected by the vicinity of these cold mountains, that neither the aloe nor the cactus, nor any succulent plant, is to be seen. Orange and lemon trees are with difficulty preserved in the sheltered valleys; the olive seldom flourishes, even in a similar situation; and they are all inferior in growth to those of Sicily, Calabria, and Greece.

The countries watered by the Euphrates and Tigris may be distinguished, by their configuration, climate, and natural productions, into three zones. The first, or most northern, comprises the mountainous country traversed by the ranges of Taurus, where the winters are cold and the summers hot, and where the productions are forest and fruit trees, olives, wine, corn, and pasturage. The second zone consists of stony or sandy plains, the fertile parts of which produce mulberry trees, cotton, maize, sesame, tobacco, and hardy labiate composite plants. The climate is characterised by great dryness, combined with great variations of temperature; and the zone comprises Northern Syria, Mesopotamia, and the low country to the east of the Upper Tigris. The third zone, which extends from Feluja to the Persian Gulf, consists of low, watery, alluvial plains, which produce date trees, rice, and pasturage, or saline plants, reeds, sedges, and rushes. The plain is intersected in every direction by the remains of ancient canals, and is still capable of the extensive irrigation which made it in ancient times the richest country in the world. But at present it is nearly a desert, and cultivation is only found like a fringe along the banks of the rivers. For the description of the remaining parts of the empire, see the articles SYRIA, PALESTINE, EGYPT, TRIPOLI, and BARCA.

The dominant race of people are the Osmanlee or Othmanlee, or Ottoman Turks. They however spurn the name of *Turk*, which they consider as a term of contempt equivalent to *barbarian*, while they glory in the name of Osmanlee, as expressive of valour and polish. Their language has received so large an admixture of Arabic and Persic, as to be denominated on that account Mulemma or the Piedmare. Nor are the people themselves of a race less mixed than their language. For ages they have blended themselves with the nations that they have conquered. They are in general a tall, robust, well-formed race, of rather harsh, yet often noble physiognomy, a tawny complexion, dark-brown hair; and their natural gravity of mien is aided by long moustaches, which are reckoned an indispensable ornament. With respect to their character, there is the greatest discrepancy among European travellers and writers, who, actuated by different feelings, views, and interests, and writing for opposite party purposes, have given such accounts of the Turks as can scarcely be reconciled, or be considered as applicable to the same people. But after a full consideration of these conflicting statements, we are inclined to be of opinion that the Osmanlee are scarcely, if at all, inferior in moral character even to some of the proudest nations of Western Europe, while they are certainly far superior to their eastern neighbours the Russians and the Greeks; the former of whom are brutalized by the bondage of the mass of the people, and the latter are as proverbial for wiles as the Turks are for honesty. The character, however, of the Turks is not uniform; those of Asia differ considerably from those of Europe. Scattered over a wide extent of country, they exhibit in different provinces different manners and customs, and some of them are certainly more barbarous than others; but instead of condemning them in the mass, as some travellers do, we think it is rather to be wondered at that, subjected as they have been for centuries to the most pernicious system of misrule, they still possess any good qualities at all, than that they are not so thoroughly humanized as more favoured nations. Their religion, bad as it has been called, seems no more conducive to immorality than that of Spain or Italy; and the general condition of the empire at the present day, and the manners of its people, will bear a favourable comparison with those of Spain or Portugal, Naples or Sicily. The total number of the Osmanlee throughout the empire is exceedingly uncertain: but their actual number has always been small in comparison with the population of the territories which they have ruled. On the one side, they are mixed with a more numerous population of Christians, whose seeming submission is a veil to their hostile feelings; and on the other, they hold in subjection an Arab population, who, from fearing and respecting their masters, have now acquired a conviction of their own superiority. The Turkish population, says the duke of Ragusa, of both sexes, and including all ages, does not, at the very utmost, exceed three millions and a half of persons, and is spread over an immense surface; only 700,000 of them are reckoned to be in Europe. The most numerous portion, indeed, of the European population consists of various Sclavonic tribes, as Bosnians, Servians, Bulgarians, who chiefly inhabit the northern, western, and central parts of Turkey. Next to them in number are the Arnauts, who inhabit Albania, and are scattered over other provinces; and to these must be added Greeks, Wallachians, Jews, Gipsies, Armenians, and Franks. No census having ever been taken of the population, the numbers of these various races can only be conjectured; and accordingly, European statists differ widely in their estimates. In the Weimar Almanac for 1840, we find the population of European Turkey classed thus:

Osmanlee, of Turkish origin and speech	700,000
Greeks	1,180,000
Albanians	1,600,000
Sclavonians	6,000,000
Wallachians of the Greek Church	600,000
Armenians	100,000
Jews	250,000
Franks	50,000
Gipsies	200,000
	10,680,000
Add the population of Moldavia and Wallachia	1,500,000
Total population of European Turkey	12,180,000

The population of Asiatic Turkey is still more various, but we have never seen any estimate of the numbers of the various races. The Osmanlee are very numerous in Asia Minor, which they seem to consider as their proper country; but even there they are mixed with a multitude of Greeks, Jews, Armenians, Yezidees, and other races, while large tracts of the interior are abandoned to the wandering tribes of Turcomans, Yurukhs, and Kurds, who pasture their flocks and herds in the wide upland plains. The Turcomans are also of the Toorkee family; but being pastoral, like the Arabs, they traverse immense tracts to procure subsistence for their camels, buffaloes, goats, and

Statistics.

sheep, which constitute the principal part of their wealth. They also breed horses, and sell them, with milk, butter, and meat, to the towns and villages, taking in return arms, clothes, and money. Their women spin wool and make carpets. Each camp is under a chief, whose power is regulated by custom and dependent upon circumstances, and the abuse of it is restrained by public opinion. They pay for the liberty of pasture, at so much a tent, to the pashas. The Turcomans are by far the most numerous and the most civilized of the nomade tribes. They live in tents during summer, but have generally fixed villages for their winter quarters. The Yurukhs live in tents all the year round, but dwell almost exclusively in the mountains; and when in the neighbourhood of large towns, generally act as charcoal burners, and supply the towns-people with that article. They, as well as the Turcomans, cultivate a little ground. The Kurds differ much in manners and language from both of these tribes. They are a more wealthy and independent people, and live entirely in tents. They dwell on the eastern flanks of Mount Arjish, and in the great plain of the Haimaneh, towards Angora. They are found also among the ridges of Taurus, in Northern Syria; but their proper country is the mountainous region to the north-east of the Tigris, which from them takes its name of Kurdistan, and which is nominally divided between Persia and Turkey, without being really subject to either. (See SYRIA, PALESTINE, ARABIA, ARMENIA, KURDISTAN.) The total number of the population of Asiatic Turkey is reckoned at 9,956,400; and the total population of both European and Asiatic Turkey is thus classed, according to their religions: Moslem, 13,552,000; Greek Church, 4,000,000; Armenians, 1,400,000; Catholics, 613,000; Monophysites, 380,000; Nestorians, 300,000; Christians of St John, 5000; Protestants, 3000; Jews, 620,000; Yezidees, 100,000; Druses, 60,000; Nazaries, 40,000. Total, 21,073,000.

Government.

The government is an absolute monarchy, or despotism vested in a padishah, or emperor, of the race of Othman. He is also, in virtue of a compact made with the last descendant of the Fatemite caliphs of Egypt, khalif or vicar of the prophet, and, as such, head of the Mahommedan religion. He thus unites in himself the power of the *kitab* and the *kilitch* (the pen and the sword), and consequently claims the exercise of an absolute authority, both spiritual and temporal. There is no limit to his power but the dread of retaliation and revenge. He cannot indeed infringe the right of property, or inflict punishment in general, without a formal condemnation; but, on the other hand, the *orlouf*, or royal prerogative, allows him to put to death fourteen persons every day, as the effect of immediate inspiration, and in these cases confiscation is sure to follow; and it is from this prerogative that he has obtained his ordinary title of Unkiar, or Hunkiar, or Khunkiar (*i.e.* the manslayer), the one by which he is spoken of among his subjects. He also bears the title of sultan, but is best known to Europeans by the Italian title of Grand Signior. The most characteristic trait, however, of Turkish despotism is exhibited in the relation which subsists between the hunkiar and his officers. All who accept any post or place (and what he offers none dare refuse), thereby place their lives and properties at his disposal; he is the heir to all their effects, and can at any time take their heads as a matter of right. In such circumstances, it is natural that the offices of government should either be in the hands of desperadoes, or of men who hope to escape notice by a servile adherence to established routine, and who sacrifice every thing to their personal safety. The ulema alone are placed beyond the reach of these odious prerogatives. There is no hereditary nobility, and thus all the prejudices of the people in favour of antiquity, nobility, and power, are concentrated upon the family of Othman, the founder of the empire and of the imperial dynasty. They stand alone in the eyes of the nation, and the care to preserve this illustrious line has never been more conspicuous than in the midst of revolutions. It was however nearly extinguished in 1808. At the very time when Mustapha IV. was put to death, executioners despatched by him were in search of his cousin Mahmoud, the sultan, who was discovered by his deliverers lying concealed under some old tapestry. Mahmoud was then the only surviving male of the family, and the circumstance of his being so is believed to have saved his life on several occasions during his turbulent reign. The government has for a long period been singularly inefficient; and if we examine the system, from the highest authority downwards, we shall not be surprised at its total unfitness for its legitimate purpose. The presumptive heirs to the throne, who bear the title of Shahzadeh (king's sons, or princes), are shut up, each separately, in an isolated apartment within the palace, in the middle of a large garden. These apartments are prisons called *kafesses* (iron cages). Surrounded by high walls, they contain only these unhappy princes, attended by eunuchs, and by female slaves too old to become mothers. The reigning sultan, seeing in them so many rivals, constantly watches their conduct; lets no one approach them; prohibits, under pain of death, all correspondence with them; and leaves them to vegetate in utter ignorance of every thing passing in the empire. He appoints for their preceptors persons in whom he has confidence, old men, who teach them the rudiments of the Arabic and Persian languages, and writing; and for their amusement, he appoints some of his eunuchs to be their pages, who instruct them in some of the most common mechanical arts. Whether they be his sons or his brothers, the treatment is the same; and such is the education of those who are destined to govern so large and turbulent an empire.

In the early periods of the Ottoman history, all the male relations of the sultan shared with him the dangers and the glories of the battle-field; but among a people prone to admire bold crimes, who had no fixed law of succession to the throne, and whose domestic manners were calculated to weaken the ties of kindred, the prince often found dangerous competitors in his sons and brothers. Selim I. deposed and murdered his father. Suleiman the Great was obliged to strangle his eldest son, who had conspired against his life; and this circumstance induced him to ordain that all the princes allied to the throne should be kept in close confinement in the palace, secluded from the public eye and from state affairs; nor could they leave their prison, unless in the presence of the emperor, till called to ascend the throne. This fatal law, dictated in the gloomy spirit of eastern jealousy, soon marred the grandeur of the race of Othman. The succeeding sultans, reared in captivity amidst women and eunuchs, were unfit to be the heads of a warlike nation, and in almost every case relinquished the command of the army, to riot in cruelty and sensuality. From Othman, the founder of the dynasty, to Suleiman the Great, the sultans were all men of surpassing vigour and abilities; but from that period their history exhibits little but weakness and disgrace.

Thus passing his youth, or sometimes the greater part of his life, till mature age, in complete idleness, deprived of every kind of rational pleasure and amusement, the heir of the empire no sooner quits his imprisonment to mount the throne, than, surrounded by a swarm of flatterers, by handsome slaves and various objects of enjoyment, he blindly plunges into effeminacy and luxury; and abandons to the mercy of his eunuchs and his flatterers the affairs of empire, in which he has never been exercised, and of which therefore he is totally ignorant. Upon the elevation of a prince to the throne, the eunuch who attended him in the kafesse as first page, becomes his kizlar-agassi, or superintendent of the girls; but generally bears the title of Daru-s'saadé agassi, or master of the palace of felicity. As ignorant as his master of the art of government, this eunuch nevertheless enjoys great power, not only in the palace, but throughout the empire. His person is considered sacred; his rank is equal to that of the grand vizir; and his influence is usually so great, that he changes and appoints the grand vizirs, the grand admirals, the ministers, and the governors of provinces. In short, the most important and delicate affairs of government are often managed by the influence of ignorant menials and intriguing women. Every Mahommedan is allowed to have four wives by the nikiah, or civil contract, besides as many slaves as he chooses or can afford; and the children of the slaves are as legitimate as those of the wives. A dis- inction is nevertheless made between the mothers; the usband can repudiate the nikiah wives, even though hey have borne him children; if a slave has borne a hild, she is entitled to her freedom before her master an part with her; but if she be barren, he can sell her t the bazaar. Sometimes also her master grants her he nikiah, which makes her free. The sultan, however, s prohibited by law from marrying even slaves by nikiah, o that he has no wives, but chooses from among his slaves hose who please him most, and gives them the title of adine, or lady. The title is conferred by the ceremony f robing, the sultan investing her with a pelisse, which an only be worn in the harem by a cadine. The num- er of cadines used to be four or five, but sometimes ore; and the late Sultan Mahmoud was the son of a se- enth. Each cadine has her separate apartment, eunuchs, nd female slaves. They never meet except on the occa- ion of an accouchement, when the mother receives a con- ratulatory visit from the other cadines. The mistress of he harem, kehaya-cadine, conducts each night one of the adines to the sultan's chamber. When he is displeased ith any of them, he marries her to one of his subjects, and kes another in her place; but the cadine who has had child, whether it be dead or living, cannot be dismissed om the palace. The sultan cannot take any of the ca- ines left by his predecessor; but, on his accession, lodges hem with their jewels and attendants in the eski-serai, or ld palace, a large building in the centre of the city, sur- unded by high walls, and destined for the perpetual abode f those cadines who survive their master. Their children, if ale, are shut up in the kafesse; but if female, they are kept n the sultan's harem, under the inspection of the kehaya- dine, till they marry, when they take their mothers from e old palace to live with them. The same thing happens ith regard to the mother of a male child. As soon as her n mounts the throne, she is taken from the old palace, eceives the title of valide-sultana, and is accommodated ith apartments in the imperial serai.

The sultan must personally inspect the efforts of the vil and military authorities to extinguish the fires which eak out in the city or suburbs, or on the shores of the osphorus. If the fire break out in the night, the silih- r is informed of it, and he instantly acquaints the kizlar- a, who enters the harem, goes straight to the sultan's d-chamber, and announces the event to the five maids ho keep watch during the night. One of these puts on a d turban, enters the sultan's chamber, approaches the d, and if he be asleep, gently chafes his feet till he awake. he sultan immediately proceeds with his retinue to the ace where the fire has broken out, and where his minis- rs also meet him. Fires are extremely frequent and de- ructive, yet the inhabitants of Constantinople and the burbs are prohibited to build their houses of stone; a ohibition which is said to have been originally a sort of ecaution on the part of the sultans against the janizaries ving, in cases of revolt, any solid building to intrench themselves in. Such was, or used to be, the padishah, and the principal members of his household. Let us now proceed to his public ministers.

All the pashas of three tails, who are governors of provinces, bear the title of vizir; but the governor of the capital bears the title of supreme vizir, or viziri-aazam, and various other exclusive titles, as veliki-mutlak, or absolute lieutenant; sahib-devlet, or possessor of the government; and sahib-muhove, or keeper of the imperial seal. It is to him that the grand admiral and the governors of provinces address their official reports; and, after having read them, he writes with red ink, on the margin of each, an abridgment of its contents, with his opinion, and sends them to the sultan by an officer called telhitzy. All the affairs of the empire, both foreign and domestic, must come under his notice. In time of war he commands the grand army, and all the other commanders are under his orders. He is also the supreme judge in both criminal and civil affairs, and his arz-odassi, or court of justice, is without appeal. Every Wednesday and Friday, assisted by the two kadi-askers of Roum-ili and Ana-doli, he hears appeals from the Istambol-effendi, or master of the city police, and from the three mollas or judges of Galata, Eyoub, and Scutari, three suburbs of Constantinople. On Tuesdays, Fridays, and Saturdays, he sits alone in judgment on criminal cases; and his sentence can be annulled only by his successor. He is also the supreme chief of the police of the metropolis, and frequently changes his dress and explores the streets, attended by some of the officers of his court, and a train of executioners. Woe then to the man who may be caught in the act of offending, or who may in any way displease him. The grand vizirs have indeed a maxim worthy of themselves. They say that "the word government, in its proper sense, means punishment." There have been times when the grand vizirs were worthy of their high dignity, but in general the case is very different. As their career is almost always terminated by the loss of their heads, or at least by banishment and confiscation of their property, the ministers of the Porte, and the silih-dar, avoid the dangerous post, and, if they have any influence, select one of the pashas of three tails, and by their intrigues facilitate his promotion to the office of supreme vizir. Most of these pashas are originally household officers, who, after having served grand vizirs, grand admirals, and governors of provinces as their pages, and then as their lieutenants or their treasurers, obtain, under the auspices of their masters, the title of kapudzi-bashy, chamberlain, or selaheuhori-shetwiyari, master of the horse to the sultan, are afterwards appointed governors of provinces of the second rank, and at last governors of the first rank, or pashas of two tails, and pashas of three tails. This office was abolished by the late Sultan Mahmoud in 1838, but has been restored by his successor.

Next to the grand vizir is the kethkudaï-sadri-ali, or lieutenant of the sublime post of the grand vizirat, whose functions correspond to those of minister of the interior. All the qualification that is required of him is a superficial knowledge of the Arabian and the Persian languages, that he may be able to read the reports of the governors of provinces, and the petitions, which he afterwards presents to the grand vizir. The applications from inhabitants of the capital he merely looks over, and then refers them to the official department to which they belong, according to their subject. The next officer is the reis-effendi, or reis-ul-kioutab, minister of foreign affairs, to which he is too often a stranger in every sense of the word, being ignorant alike of history, geography, statistics, forms of government, diplomacy, the interests and relations of foreign states, and even of any of the languages of Europe. The minister of finance bears the title of defterdari-chikki-evvel, or keeper of the register of the first division of the exchequer. This department is divided into various offices; such as that of confiscated property, and of the property of persons dying without heirs; that of debts to the state; and that of the piscopos, in which the berats or diplomas of the Greek patriarchs, archbishops, and bishops, are drawn out. The intendant of the great custom-house, and of those of Galata, of the snuff and tobacco custom-house, the receiver-general of the haradz, or capitation tax on infidel subjects, and many others, are also under the minister of finance. Persons are frequently appointed to this important office who are ignorant of even the first four rules of arithmetic. If he be an easy man, the clerks and the chiefs of office, in order to be sheltered by his credit and protection, give him part of what they steal from the state. If, on the contrary, he is not a man to be duped, he plays with his subalterns the part of the lion in the fable, and enriches himself at the expense of the state, exhibiting at the end of the year an enormous deficit, which is supplied by anticipating the revenues of the next year, and so on, till his wealth again return to the sultan by his death or confiscation. These deficiencies of the treasury have at times occasioned so much embarrassment and distress, that, in order to provide for the urgent expenses of the state, more than ordinary recourse has been had to confiscations, and the government has seized all the property of condemned persons, without paying their creditors. The ministry of war is divided into several intendancies. There is the tophane-naziry, or intendant of the cannon foundry; the barut-khané-naziry, or intendant of the powder-mills; the khoumbara-naziry, or intendant of projectiles; and the dzebe-khané-naziry, or intendant of the ammunition. All these ministers make reports to the grand vizir, who presents them to the sultan. Affairs of such great importance as these, and which require precise and detailed knowledge, are, like every thing else, intrusted to ignorant people, whose reports are revised by one more ignorant, and decided upon by the sultan, who is usually the most ignorant of all. The tersané-emanety, or ministry of the marine, superintends the revenues of the admiralty, the purchase and provision of all that is necessary for the building and equipment of ships of war, and the payment of the naval officers and seamen. It is nevertheless almost always intrusted to persons who have not the slightest idea of affairs so complicated as those of the marine. The revenues are received by the clerks, the tersané-capudani-emini or directing minister, and the derya or grand admiral. This last-mentioned officer, who is usually styled the capitan or capudan pasha, is of very high rank and importance in the state; but, unfortunately for the successful performance of his duties, he is usually a person utterly ignorant of seamanship and naval tactics. The most favoured dignitaries of the palace have aspired to and obtained this lucrative and brilliant post. The late sultan Selim's first page, Hussein Pasha, was raised to it. The admiral chosen to oppose Sir John Duckworth's passage to Constantinople in 1806, was the mirahovi-ewal, or master of the horse, and he was succeeded by Hassan, the kassab-bashy, or chief butcher. Several bostandji-bashy, or captains of the palace guard, have also been appointed, it being supposed, that as they steer the sultan's caique on the Bosphorus, they are thereby qualified to direct the operations of fleets. Even men brought up in the interior of Asia Minor and Syria, and who have never seen the sea, have been promoted to this post, and have even been assisted up the ladder of the flag-ship, for fear they should fall into the water. These admirals used to sail every year from Constantinople with a part of the fleet, to visit the islands of the Archipelago, which were under their special government. In their progress they used to spread alarm and desolation, plundering and annoying the inhabitants; and, in order to show their master that they had put his maritime possessions in order, they have decorated the rigging of their ship, on returning to the capital, with the hanging bodies of some unfortunate islanders. The officers under him are, like himself, unfit for their duties, and follow his example in committing all sorts of atrocities, deriving their principal emoluments from extortion and rapine. The grand admiral is obliged, when he is at Constantinople, to appear every Friday in state at the palace, and pay homage to the grand vizir, whom he acknowledges as his superior; but the latter, in his turn, when the admiral approaches making a profound bow, and advancing to kiss the hem of his pelisse, draws back his robe with haste, and salutes him in the same manner, with a bow to the ground.

Various changes, however, have been made by the late Sultan Mahmoud and his successor, and our preceding account will better apply to things as they were than to things as they are; for Mahmoud thoroughly reformed his household, abolished all sorts of useless offices, and carried his retrenchments of expenditure to the most radical limits. At the beginning of the present year, the principal officers of government were, 1. the sheikh-ul-islam, head of the clergy: 2. the grand vizir: 3. the two kadi-askers of Roum-ili and Ana-doli: 4. the ministers of the first class, namely, the minister of war and commander-in-chief of all the regular troops; the seraskier, or commander-in-chief of the troops in Ana-doli; the capudan pasha, or high admiral; the minister of commerce; the captain of the guard; the minister of finance; the minister of foreign affairs (formerly reis-effendi); the chaousch-baschi, executor of the judgments of the divan; the chief physician; and the president of the board of health: 5. ministers of the second class, namely, the secretary of state; the treasurer of the sultan's income; the beilikschi-effendi, assistant to the reis-effendi in the executive department of his office; the master of the ceremonies; the director of the wakufs, or charitable institutions; the interpreter of the Porte; and the director of the customs. The council of ministers is called the divan, from the circumstance of their meeting in a certain room of the palace, which has no other furniture than a *divan*, or wooden bench, along the wall, about three feet high, covered with cushions. It is here that laws are made, suits decided, firmans issued, troops paid, and the representatives of sovereigns prepared to be introduced to the august presence of the sultan. The imperial court itself is usually called by Europeans, in French phraseology, the Sublime Porte, a name which it derives from the *Bab-humayoun*, the principal port or gate of the outer wall of the palace, from which the imperial edicts are dated.

For administrative purposes the empire is divided into provinces called *eyalets;* the larger of which are governed by pashas of three tails, with the official title of vizir; and the smaller by pashas of two tails, with the title of miri-miran. The eyalets are subdivided into districts, called livas or sandjaks, each under the charge of a pasha of one tail, with the title of miri-liva, or sandjak-bey; the cities and towns are governed by mutselims. The provinces are usually called pashalics by Europeans; *pasha,*[1] however, is not an official title, but is merely a personal honour, like knighthood in Europe, conferred by the sultan. There are three ranks of pashas, the first or highest of which has the privilege of bearing a standard with three horse-tails; the second, of two; and the third, or lowest rank, of one. Under the old system, the pasha was invested with the full powers of absolute government within his province. All power was united in his person; he was the chief of both the military and the financial departments, of the police, and of criminal justice; he had the power of life and death, of making peace and war; in short, of doing what he pleased, so long as he could purchase and secure the favour of the sultan and his ministers. The provinces were indeed sold to the highest bidder, and the successful candidate was sent to his province with full powers to make the people disgorge as much of their money as force and cunning could squeeze out of them. The Porte received the stipulated sum from its nominee, without inquiring how it was procured; and to such a pitch was the tyranny of the pashas carried, that many districts offered the sultan to pay directly into his treasury more than three times the nominal sum demanded of them as taxes, provided the money might be collected by an officer totally distinct from the pasha. At length Sultan Mahmoud, in the course of his reforms, ordered that with each pasha should be associated an officer charged with the collection of the imposts, independently of the pasha; but whether from a difficulty of finding persons qualified for such an office, or from other causes, this order had never been carried into effect up to July 1834, when Marshal Marmont, duke of Ragusa, was at Constantinople; and the cupidity and injustice of the pashas and mutselims, the marshal states, were never greater than at that time. We learn also from the sultan's hatti-sheriff, issued in November 1839, that the venal concession of offices then still subsisted; that the civil and local administration of each region was still, at that time, delivered up to the arbitrary will of one man; and that the people still had no security for person or property. Yet we are told by an anonymous writer in 1838, that this state of things had already been very generally altered; that the pasha was then a salaried military and civil officer, without the power of life and death, and personally uninterested in the revenues of his province; that a treasurer from the Porte then received directly from the communes the amount of their contributions. The result is stated to be highly gratifying, the people contributing a fixed and a higher sum to the state than the former nominal one, but in reality much less than what the pashas used to extort from them. The imperial treasury is stated to have greatly improved in its receipts, the subjects paying less, while the government receives more.[1] So little are writers on Turkey to be trusted.

---

[1] This word is spelled *pacha* in French, and is merely a new-fashioned form of the old and familiar word *bashaw.*

gion
laws.

The Osmanlee are all Mahommedans, and Islam is the religion of the state; but all other religions are freely tolerated, and with their professors the Osmanlee live in the utmost harmony. Both the law and the religion being founded on the same common basis, the Koran, the clergy and the lawyers form but a single order, divided however into two classes, the ministers of religion and the ministers of justice; for the prayers and ablutions prescribed by the Koran are so numerous and so frequent, that the ministers of religion could never find leisure to execute the office of a judge; they form therefore a separate class, leaving the administration of justice to the cadis. Every Osmanlee is entitled to become a member of this body, but he must first receive a suitable education. After a few years' study, and an examination of his capabilities, the candidate may be admitted to the service of a mosque; but having once entered upon the sacerdotal office, his career is closed, and no further promotion awaits him. Those who aspire to higher honours continue their studies for a longer time, and, after several examinations, obtain the rank of *mulazim*, which entitles them to hold the office of deputy to a cadi or judge. If their ambition urges them still farther, and they wish to obtain the degree of muderis or doctor, their noviciate must be continued seven years longer, and they undergo a final examination in presence of the mufti. The title of muderis being once conferred, the first dignities of the magistracy lie open to their hopes. The classification, however, does not end here; the muderises of Constantinople are divided into ten classes or degrees, from the first of which only are chosen the supreme magistrates of the state. This exact organization gives to the clerical body a firm coherence, which makes it the most solid part of the Ottoman institutions. Its unity is secured by the controlling authority of its head, the grand mufti, or sheikh-ul-islam, from whom depend all the appointments to its various ranks and offices, while the members have all a common interest in maintaining its privileges. Of all the offices in the state, that of grand mufti, or sheikh-ul-islam (head of the faith), is alone held for life. He is the oracle of the law, and the representative of the khalif or sultan in his spiritual capacity; and as all new laws, and even the question of peace and war, must await his sanction, he thus participates in the legislative power of the sovereign, and interferes with all the movements of the government. The privileges common to all the members are exemptions from taxes and arbitrary imposts, arbitrary confiscation, and the punishment of death. They are sufficiently enlightened to understand their interests; the prerogatives on which they depend are of the most solid and important nature; their chiefs are bound to them by the strongest ties, or are proved by long novitiate or repeated trials; they unite the firmness of an aristocracy to the spirit of a profession; in fine, their influence has naturally such a good foundation, and is so artfully fortified, that it would be extremely difficult to overturn it. But all the advantages which result from their combination are exclusively their own; they cannot resist the arbitrary violence of the sultan, but they can impede the alterations of the law. Their power is founded on the false principles which would arrest the progress of civilization, and they are the natural supporters of the present state of things. In the Ottoman empire there is nothing of a solid construction, except this bulwark against innovation. It is difficult to reform law and religion, even when taken separately; but when united, they offer an inert, or even an active resistance, sufficient to baffle the strongest efforts of the best-intentioned despot. The whole body is termed the Ulema.

To give, however, a precise idea of this important body, we should begin with the students, who are called *sukhte* (vulgarly pronounced *sokhta*, or the scorched), because it is supposed that they burn with a zeal for knowledge. There are schools or colleges, named medreses, established in all the imperial mosques in Constantinople, Adrianople, and Brusa. The pupils first study grammar, and then Arabic and Persian poetry, and rhetoric. When considerably advanced in the Arabic language, they apply themselves to the reading of the Koran, the commentaries upon it, and the books which treat of the civil law. Finally, they study logic, natural philosophy, and metaphysics, in old Arabic works. Totally neglecting mathematics, they also study judicial astrology, as the most sublime branch of human knowledge. Such is the sum of information possessed by the sukhtes. They are chiefly from Syria and Asia Minor, very few being from European Turkey. They are the most savage, the most fanatical, the most turbulent, and the worst subjects, among the Turks. Their number also is so considerable, that Constantinople alone contains above 10,000 of them. They perform, in their clerical quality, the services of the mosques; their daily sustenance is regularly furnished out of the revenues of these temples; and they are lodged in the numerous cells annexed to them. But as most of them are poor and unprotected, it is very seldom, and only when at an advanced age, that any of them attain the chief clerical dignities. The student who has neither patronage nor distinguished talent to carry him through the ten degrees of muderis or doctorship, which lead to the higher dignities of the law, aspires only to inferior offices; and the greater number of them reach only the rank of simple cadis or judges of Naïb, or subdelegates of the judges in the towns and villages. Riches, birth, and patronage, the powerful instruments of worldly advancement, exercise their usual influence in this body. The first step of promotion is, when, after many previous trials, the student is inscribed in the list of those who aspire to legal offices, and as such, upon the mufti's verbal intimation, called *ishriet aliyah* (the high wink), obtains a written document from the supreme judge, denominated *mulasimet gayadi* (the writing of reversion). Next, if the mulasim acquit himself well in the prescribed trials, he obtains a *medrese* of the lowest income, and afterwards advances, by regular gradation, to the highest rank of the medreses, that of the suleimaniyeh, and then the eldest among them are promoted to the rank of *mahrejmolla*, or superior judges. These posts of mahrejmolla are eight in number, namely, those of Galata and Eyoub, suburbs of Constantinople, Scutari, Smyrna, Salonika, Larissa, Haleb, and Jerusalem. Their function however lasts only a lunar year, when they are succeeded by others. The next step of promotion by seniority is to the four superior mollaships of Adrianople, Brusa, Damascus, and Cairo; the next to the two titular mollaships of Mecca and Medina; and one is further promoted to the rank of Istambol-effendi, or master of the police of Constantinople. The next step from this rank is to that of kadi-asker of Ana-doli, and then to that of kadi-asker of Roum-ili or European Turkey, and finally to the supreme rank of grand mufti. The grand mufti and the two kadi-askers always reside at Constantinople. Another of the members of the ulema is the nakib-ul-eshraf, or chief of the emirs. There are also four whose function is within the sultan's palace.

---

[1] British and Foreign Review, vol. vii. 121.

Before a simple sukhte can arrive at the high dignities of kazi-asker and grand mufti, a period of twenty-five years must elapse; but the great ulema, vizir, and other officers, abusing their power and influence, procure for their children from their birth the honorary title of muderis, and afterwards of the other degrees of office, without their ever filling them.

The law being, as we have said, but an extension of the religion, the whole civil code of Turkey is founded on the Koran, and the edifice is completed by dialectic subtilty. Where sacred texts are wanting, traditionary tales, or constructions put upon the silence of the prophet, supply their place, and the involuntary fraudulence of ingenious reasoning pervades the whole. Neither are the inherent vices of the code corrected by the manner of its administration.

Besides the chain of the ulema, there is yet another perfectly distinct chain of clerical personages, that of the *sheikhs*. This title is borne by the grand mufti, who is the sheikh-ul-islam, and under him by the superiors of monasteries, and the *wais*, or preachers at the imperial mosques. The sheikhs of monasteries, however, have no graduated course of advancement; but the sheikhs of the imperial mosques have, like the chain of the ulema, an actual course of advancement according to the ranks of their respective mosques. There are at present twenty mosques in Constantinople which bear the title of *humayoun* (imperial); and of these, four were built by the late Sultan Mahmond.

The whole system of internal administration in Turkey was directed to the accumulation of money, and the avarice of the sovereign was diffused through all his officers. Before November 1839, every office was sold, with an understanding that the purchaser might use any means to reimburse himself. Corruption pervades every department of the state, civil, legal, and ecclesiastical; and under its baneful influence the provinces have been made deserts, and the empire brought to the verge of ruin. The late Sultan Mahmoud, indeed, made many vigorous efforts to reform abuses; and his successor Abd-ul-mesjid (servant of the mosque) has issued a hatti-sheriff, published 3d November 1839, promising to seek, by new institutions, to procure for the provinces of the empire the benefits of a good administration. These institutions relate principally to three objects; first, guarantees for the security of honour and property; second, a regular mode of fixing and levying taxes; third, a regular mode of levying soldiers, and fixing the duration of their service. This edict has been pompously called the Magna Charta of Turkey; but such deep-seated corruption and abuses as we have described are not to be cured by edicts.

Financ

The revenues of the state are raised by a variety of imposts; but as the government publishes no accounts, we have no means of stating correctly the amount that reaches the imperial treasury. The Christians and Jews are subjected to a haradz or poll-tax, and other vexatious imposts, from which the Moslem population are exempt; but even of the latter the burdens are sufficiently heavy. The agriculturists, besides tithes, the merchant, besides enormous custom-house duties, the artisans and workmen, besides what they contribute to their respective corporations, are subjected to innumerable vexatious impositions. In the simple institutions transmitted by the Arabs to the Turks, which have formed the safeguard of the empire against internal abuse and foreign encroachment, direct taxation was an essential element. With the exception of the capitation tax levied on the rayahs, or infidel subjects, in lieu of military service, the whole regular revenue of the empire used to be derived from the *miri*, a sort of property-tax (or rather the land-rents of the country, of which the sultan is the sole proprietor, the people having only the usufruct), assessed and levied, not by any acts of the central government, but by each community within itself. A certain sum was fixed as the contribution of every village or district, proportioned to its means; and each member of that district paid his share according to a rate assessed by the municipal council. When however Mohammed II. introduced the system of farming the revenue, he subverted the functions of these municipal councillors. They retained their office and title of *ayan*, but had no longer any control over the pashas, who had purchased their places, and thereby become owners or farmers of the revenue. Previously, says D'Ohsson, they were members of the provincial divan, to advise in the administration, and could interpose their influence against oppression. These municipalities still exist, and are acknowledged by the government, but their power is more silent and limited; yet it is principally to them that Turkey is indebted for the preservation of its social organization and order amidst so many misfortunes, and under such a long continuance of misrule. Indirect taxes have also been introduced, corresponding to our excise and customs; and certain duties are now levied upon the export and import, the transit, and the sale of merchandise. The revenue, compared with that of former periods, is reduced by the loss of Greece, Moldavia, Wallachia, Servia, Bosnia, Egypt, and Candia, all of which have become more or less independent; while Albania, Bagdad, Erzroum, Kars, and Akhalzikh, paid little or nothing for many years, owing to the complete disorganization of the government in these provinces. On the other hand, the regular expenditure for the army, the navy, and the other branches of government, has been gradually increasing till it has more than doubled; yet there is ground for asserting, not only that the revenues fully meet that expenditure, but that there is actually a surplus.

Arm

The celebrated corps of janizaries was formed at first of slaves and captives, but its ranks soon became filled with the bravest of the Osmanlee; and as a military brotherhood affords some chance of protection from arbitrary power, ll crowded to the muster-roll of the janizaries. The mul-itudes, however, of which the order at last consisted, were ot all subjected to military discipline, and only served to ll the empire with turbulence and confusion, without in-reasing its strength. The number of janizaries enrolled t the close of last century was about 400,000; pay was ssued for 60,000, but not more than 25,000 men could at ny time be mustered during the Russian wars. The corps as originally formed as a protection to the sultan against is powerful subjects, military or feudatory chieftains; but ey soon became corrupted, and the danger of a pam-ered and licentious soldiery was speedily felt. Bajazet II., ithin a century and a half after they originated, formed a an for their destruction; and Murad IV. destroyed great umbers of them, without however exterminating the corps. elim III. forbade the recruiting of them, and this cost m his life. The suppression of the janizaries became at st essential to the security of the sovereign and the state; d by one deadly blow, dealt by the late Sultan Mah-oud, that haughty soldiery, to whose predecessors the em-re owed the largest share of its extent and glory, was tally extinguished in 1826.

A sense of their declining strength has induced the sul-ns, since the beginning of last century, to aim at intro-icing some military reforms, and to endeavour, by the option of European tactics, to retrieve the tarnished ory of their arms; but with small success, till the reign of e late energetic Sultan Mahmoud. After the destruc-on of the janizaries, he determined that the nizam-jedid, new military force, should adopt the European dress d tactics. He however found his Moslem subjects so pugnant to these innovations, that he was obliged to rol only very young men, whose prejudices could not be ry deeply rooted, and merely retained a small number of l soldiers to incorporate with the new levies, which were sed by conscription, mostly in Ana-doli. The French stem of tactics was the one selected for the infantry, and ench officers were appointed to be their instructors; but ough the soldiers possess zeal, diligence, and habits of eat attention, when under instruction, their instructors ve hitherto failed in forming them into an efficient army. eir officers are selected and promoted in the same way the officers of the civil and legal departments; and in-mpetent persons are still appointed to the most responsible uations.

An important part of the army used to consist of the his furnished by the timariots, or great feudal proprie-s of lands in Ana-doli, in time of war, to the amount of out 20,000 good cavalry; but Sultan Mahmoud destroyed se fiefs, and the cavalry soldiers are now levied, like the antry, by conscription; and the French system has been opted for their instruction. The horses are strong and tive, and, though not large, they have more bone than ab horses, and are admirably calculated for light cavalry. e riders are armed with swords and lances, and are gene-ly finer men than the infantry. The artillery are how-er the best soldiers in the army, and work their guns th great dexterity. The soldiers, Marshal Marmont states, better fed than any other troops in Europe; their maga-ies are filled with stores, and the regiments have large serves; their pay is twenty piastres a month, the whole which they receive; and, in short, every thing has been ne that could promote the comfort of the soldier. Their struction is carried on in a mild and explanatory manner; rshness is indeed unnecessary, as the men are naturally lerly and well disposed, and show great anxiety to ac-ire a knowledge of their duties. Owing to their habits sobriety, offences against discipline are infrequent. For all offences the soldiers are liable to be caned; and for ose of a grave nature they are subject to the same pu-shment that would be inflicted on civilians. At the commencement of the present year (1840) the force of the army was estimated to consist of 94,000 infantry and artillery; 25,000 regular, and 100,000 irregular, cavalry.

Statistics.

Navy.

The Osmanlee have never been a maritime people, or paid any attention to the art of navigation. Their military navy, after its triumphs in the fifteenth century, was long neglected; but at last, into this department, as into every other, the Sultan Mahmoud infused his energy, and succeeded in creating a very respectable fleet, which he left to his successor. At the epoch of his death, however, the capudan pasha carried off the fleet, then at sea, and delivered it up to the pasha of Egypt. At the commencement of the present year, 1840, the number of ships, including, we presume, those at Alexandria, was reckoned to be ten sail of the line in serviceable order, and five unrigged; ten frigates on service, one in dock, and four unrigged; and three steam-ships, besides several corvettes and other smaller vessels. Before the Greek insurrection, the fleet was manned by the Greeks of the Archipelago; and their pay was furnished by the Greek nation. The patriarch of Constantinople was empowered by an express order of government to impose the requisite sum, called *mellahiye*, or the sailors' pay, on the Greek inhabitants of the capital, and, through their archbishops and bishops, upon those of the provinces. But the fleet is now manned by landsmen trained in harbour, and commanded by officers ignorant alike of seamanship and of naval tactics. It is only an expensive toy.

Literature and science

There is no nation more passionately attached to literature than the Osmanlee; and from the earliest periods of their history they have devoted themselves to its cultivation. Their dialect is the most polished of all the Turkish idioms; rich, dignified, and melodious. In delicacy and nicety of expression it is not perhaps surpassed by any language; and in grandeur, beauty, and elegance, it is almost unequalled. In the department of polite literature they do not yield the palm of superiority to any nation. In poetry they display great genius and taste; all classes are its ardent admirers; and to so great a degree has the love of poetic composition been carried, that there is no class of society which has not contributed towards it. The ladies, the sultan, his ministers, doctors, soldiers, all have devoted themselves to the cultivation of poetry; and the divans, or poetical collections of above six hundred authors, are existing evidences of the taste of the Osmanlee for the productions of the muse. In the kindred department of the drama, they are however sadly deficient, for they have no theatres; nor have they opportunities of cultivating oratory. In philosophy they have all the speculative knowledge of which the Greeks and the Arabs were masters. In moral philosophy, and in the sciences of government and political economy, they are said to excel; which is the more surprising, as our ideas of the Turks and their polity would lead us to a very different conclusion. In history they possess several good works, particularly those of the early periods of the empire. There has been also a regular series of imperial historiographers; but, generally speaking, of all the branches of knowledge, history and geography are the most neglected by the Osmanlee. From the earliest periods, they possessed the best masters of astronomy; and they have a multitude of astronomical works, many of which display great science. In many of the mosques of Constantinople are to be found solar quadrants, fitted for taking observations; and astrolabes, telescopes, and other instruments of their own manufacture, some of them extremely well constructed, are in frequent use. Geometry, algebra, and arithmetic, are considered among the necessary acquirements of a man of education; and a course of these sciences forms a portion of the studies of their schools. In the science of numbers their proficiency is very great, and the facility with which their calculations are performed has been frequently observed. On these subjects they possess many excellent works. Their philosophical productions are very numerous, but their speculative and metaphysical writings are similar to those which issued from the schools of Europe during the reign of the Aristotelian philosophy; and it must be admitted, the philosophy of Bacon and Newton has not yet shed its light over the Ottoman empire; in every department of practical science, and of its application to the arts, they still remain extremely ignorant. Their moral philosophy is, however, a science on which they seem to have bestowed their best energies; it is the subject of many excellent and valuable treatises. Their mode of conveying the principles of morals, by means of imaginative discourses and apologues, adds great force and beauty to the sentiments; and strewing the path of knowledge with flowers, renders the acquisition of it at once agreeable and impressive. The only foreign languages, however, which they study are the Persic and the Arabic, and many Turks are authors of Persian and Arabic works. Only two centuries ago the literature of Turkey surpassed that of Europe; and it was from a Turk that D'Alembert took the idea of the *Encyclopédie;* but unfortunately the want of the press has kept them stationary, while, by its aid, Europe has been making rapid strides in both literature and science. A Turkish printing press was for the first time established at Constantinople in 1726; in the course of fourteen years it published three-and-twenty volumes, and then ceased. After an interval of more than forty years, the experiment was repeated. During the reign of Selim III. printing became a part of the new order of things, and the establishment was fixed in the barracks of the new troops at Scutari; but when the revolution of 1807 broke out, the whole was reduced to ashes, and few of those connected with it escaped the fury of the janizaries. During this second period of its existence, not more than forty volumes issued from the press. It was, however, a third time restored by Sultan Mahmoud, and established at Constantinople itself, and has already issued a number of important works. It is, however, still a government undertaking, and no private individual or company seems ever to have thought of introducing this useful art as a branch of trade. The government now issues a state gazette, with the title of *Takwimet-Tewaru* (Register of Events), which is far richer in matter than the *Moniteur Ottoman*, a French weekly paper, also published at Constantinople. It appears weekly, and gives the most important information touching the reforms in the organization of the state and of the army; the changes in governments, official situations, and the army list; the ships clearing inwards and outwards; and the current prices of goods; together with extracts from European newspapers, concerning the incidents in the policy of Europe. But in the art of bulletin rhetoric, and the puff style, the Register of Events, though edited by the imperial historiographer, surpasses all European newspapers.

Owing to the multitude of offices connected with the law and religion, which can be filled only by those who have been qualified by a regular course of study, the number of those who possess the requisite elementary acquirements is very great, and the means of education are most abundant. The schools divide themselves naturally into those for children, or A, B, C, schools (*mekteb*); the general instruction given at the mosques (*dersi-aam*); and in the colleges (*medreses*); all of which have subsisted in the empire from its beginning, founded first at Nicæa, then at Brusa and Adrianople, and afterwards by the conqueror at Constantinople, and having been regulated and increased to a considerable number under his successors, especially by Suleiman the Lawgiver. In the children's schools, which abound in every corner of the city, the master (*khoja*) teaches spelling, reading, and the principles of grammar and religion. In the mosques, again, the pupils receive general, easily intelligible, and popular instruction, upon philology and religion, as is indicated by their title of *dersi-aam*, which means general instruction. The lecturers are not khojas, but *muderis* (doctors or professors) of a medrese or college. Lastly, in the colleges, the students receive instruction in the higher and more difficult branches of knowledge. These colleges, usually founded beside mosques, libraries, monuments, and sometimes unconnectedly, are presided over by a professor (*muderis*), which however may be better translated rector, master, or head of the college, because he superintends not only the course of instruction, but likewise the conduct of the students who dwell in the medrese, as scholars upon the foundation. Out of about five hundred such medreses existing throughout the empire, Constantinople alone possesses three hundred. The most celebrated are those founded by the conqueror Mohammed II. and by Suleiman the Great, in connection with their respective mosques. As in Islam all instruction is founded upon religion, and jurists are at once theologians and lawyers, it is natural that mosques should always have been the central points round which scientific institutions are grouped. Thus in the Constantinopolitan mosques are found united the learned institutions, not only of general lectures and of the medreses, but also of libraries; and, finally, other three establishments for education, unconnected with the medreses, and specifically founded. These are the school of medicine attached to the Suleimaniyeh mosque, and the lecture-rooms of the Koran and of tradition. Sultan Mahmoud has reformed the medical school, and founded a nursery of physicians and a school of surgery, from which the military hospitals now established at Constantinople are to be supplied. He has also enlarged the school of engineers founded by Sultan Selim, and connected with it a school of architecture. He also instituted a naval college; several other educational institutions were also established in his reign, both by himself and by private persons; but under the reign of his son, they seem to be falling to decay, and the old system seems to be again restored. In the mathematical sciences, and especially in those branches most immediately applicable to the art of war, more was done under Mahmoud's reign than had been accomplished under all his predecessors; yet it cannot be affirmed that the present tendency of Ottoman literature is foreign or European. It can lose but little of its rigid stability, so long as the constitution of the ulema remains unaltered.

At Constantinople there is a great number of public libraries. D'Ohsson estimates them at thirty-five, others at fourteen or eighteen; but no works are arranged on the shelves, or included in the catalogues, but such as are written in the languages of Islam, namely, Turkish, Arabic, and Persian. If any others exist, they are thrown aside as lumber, and left to decay; and it is believed, that with due diligence much classical literature might still be rescued from the dusty chests of the serai. There is no good reason for supposing that the library of the Palæologi was destroyed by the Ottoman conquerors. Mohammed II. was an accomplished prince, the patron of letters, and versed, it is said, in the Greek language. On the conquest of Constantinople, he immediately took possession of the imperial palace; why, then, should he destroy the library? There is not only no account of its destruction, but there is positive evidence of the existence of an immense quantity of manuscripts in the Greek, Latin, and other foreign languages, not indeed in the library, but in the store-rooms of the serai, where they perhaps remain shut up in chests.

Turkey is not a manufacturing country, and the people have no pretensions to compete with the science and capital of Britain; but their fertile territory and happy climate enable them to supply many of the materials for foreign manufacture; and these and their other agricultural products they are content to raise, and to receive whatever can be supplied cheapest and best in return. There are neverheless several places distinguished for the production of xcellent manufactured articles. The carpets of Anatolia requently combine economy and comfort in use, with elegance of pattern; while in the beauty and durability of he colour, they are only equalled by those of Persia, which urpass them in delicacy and costliness. The Turks, howver, have never attained the art of making woollen cloths, xcept of the coarsest kind; but other branches of manu- acture are shewn to be active in the country, from the ncreased importation of cotton twist. The coarser and ore common articles of their manufacture, such as mus- ns, ginghams, handkerchiefs, cannot compete with those f England; but the finer fabrics of silk and cotton still aintain the competition, and are likely to do so, from eir superior excellence, beauty, and durability. Silk uffs are made at Constantinople and Salonika; the bra- iers and ironsmiths of Shumla have carried their art to reat perfection; good steel is made at Bosna-Serai, Scu- ari, Karatova, and Constantinople; and fire-arms at Se- endria, Grabora, and other places. The grand com- ercial principle of Turkey is unlimited freedom of trade; nd though the late Sultan Mahmoud, under evil influ- nce, endeavoured to enforce prohibitions on the export r import of certain articles, yet these prohibitions and l monopolies have been again abolished, and the trade now only limited and restricted by the extent of the apply and the demand. The principal articles of ex- ort are, horses, beeves, and swine; tanned and raw hides; ool, wine, tobacco, cotton; currants, almonds, figs, dates, d other fruits; olive oil, wax, honey, opium, raw and spun lk, camlet, carpets, morocco leather, gall-nuts, valonia, adder, gum-dragon, sponge, copper, alum, &c.; while, on e other hand, they receive corn, and every sort of manu- ctured and colonial produce.

There has long been a commercial relation between Eng- nd and Turkey; and till a recent date there existed in ondon a Turkey company, possessing the exclusive privi- ge of trading to the Levant; but the trade once carried n by the company had dwindled away, and the origin of r present trade with Turkey is but of recent date. Be- re the last war between Britain and Turkey in 1807, but vo or three British vessels proceeded annually to Constan- nople with assorted cargoes. Of these, cotton goods rmed but a small proportion; and very few also were sent Smyrna. When Malta had become a depot for our trade the Mediterranean, the Greeks, imbued with an almost tuitive talent for commerce, began there to make pur- hases of British manufactures, and sent from thence every riety of goods likely to suit the market, chiefly to Smyrna, om which the capital was supplied. An English merchant stablished a house at Constantinople in 1812, and for se- eral years it had the whole command of the direct trade ith England. From that period Constantinople became rival mart with Smyrna, which it has at length completely clipsed in the supply of British manufactures. The trade as gone on continually increasing; and no country affords better field for commercial enterprise. Besides the Eng- sh houses, there are now upwards of seventy Greek houses hich trade with England from Constantinople, besides a umber of Armenians and others, and most of the French, ustrian, and Italian merchants. About one fourth of the ame number probably exist at Smyrna, and there are se- eral at Salonika, and in the principal towns of Syria. Be- des English merchants and manufacturers engaged in usiness with Turkey, there are eight Greek houses in Lon- on, with two branches at Manchester; four Armenian and yrian, and one Anglo-Levant; in all thirteen Levantine rms, each enjoying respectable or first rate credit. The roportion of British produce and manufactures now sent Turkey is one twenty-fifth of the whole quantity export- d. It is one fifth of that sent to the United States of America, one half of that to Germany, four fifths of that to Holland, Italy, and Brazil respectively; it exceeds by one third the exports to Portugal and France; and the whole to Sweden, Norway, Denmark, Prussia, and Spain together; it equals the amount to Russia, and nearly that of our North American colonies; it falls short little more than one third of our exports to the East and West Indies, and is double the amount to China. The trade is now principally carried on by native merchants and their commission-houses or partners in England, and is shared with English houses; and, consisting only of real transactions, and affording no scope for speculation, it has been more steady and secure than that with any other country. Goods for Persia, however, form of late years the most valuable part of the shipments for Constantinople, which is not only in the direct road, but likewise offers great advantages from being an intermediate market. From Constantinople the goods for Persia are sent to Trebizond, and thence overland through Armenia.

Previously to the convention of 16th August 1838, the only recognised duty on imports from Britain was three per cent.; but other duties were subsequently levied at and after the sale of the goods imported, in a manner as oppressive as the duties themselves. By the convention of 1838, the duty on imports is fixed at the same rate of three per cent.; and in lieu of all other and interior duties, one fixed duty of two per cent. is established, on payment of which all goods imported may be sold and resold, without further duty or restriction. With regard to exports, the only recognised duty was also three per cent.; but other duties, fluctuating in their nature, and enormous in amount, were levied, at the caprice of the authorities, on all articles of any value, and especially on valonia, silk, oils, and opium. By the convention of 1838, the duty on exports to Britain is fixed at three per cent.; all monopolies and prohibitions are abolished; and instead of all inland duties on goods to be exported, one fixed duty of nine per cent. is established.

According to the last published returns, the number of vessels that entered the port of Constantinople in the years 1837 and 1838 was 3671 and 5625. The number of British vessels in 1837 was 432, with a tonnage of 86,253; and in 1838, vessels 419, tonnage 120,860. Of Ionian vessels the numbers were, in 1836, vessels 263, tonnage 41,852; in 1838, vessels 308, tonnage 45,793. Of the vessels of other nations the following numbers are given, without the tonnage, of which the British consuls have no account. In 1837, American 3, Austrian 732, Belgian 4, Danish 2, Dutch 2, French 19, Greek 832, Neapolitan 15, Prussian 5, Russian 555, Sardinian 793, Swedish 9; total 3671. In 1838, American 3, Austrian 811, Belgian 15, Dutch 7, French 48, Greek 2228, Neapolitan 84, Russian 570, Sardinian 866, Swedish 4, Tuscan 36; total 5572. Of Turkish vessels there was no account in either year; and of the Greek the average tonnage is stated to be very small compared with the number of vessels, among which are included craft of all kinds and of every size. The number of vessels that entered the port of Adrianople in 1837 was 7, of which 3 were British, 1 French, and 3 Greek; the port of Salonika in 1837, 329, of which 5 were British, 3 Maltese, 4 Ionian, 6 French, 15 Austrian, 2 Russian, 13 Sardinian, 243 Greek, and 38 Turkish; the port of Smyrna in 1837, 897, whereof British 110, Ionian 20, Maltese 4, American 13, Austrian 145, Dutch 6, French 61, Greek 498, Russian 17, Sardinian 18, Swedish 5, Turkish not known. The number of vessels that entered the port of Trebizond in 1837 was 131, of which 31 were British, 73 Turkish, 19 Austrian, 4 Russian, and 4 Greek; tonnage, 22,349; value of cargoes, L.1,145,471, whereof L.623,372 were those of the British vessels.

TURKI, a town of Hindustan, in the province of North Bahar, pleasantly situated on the Bogmutty river, and formerly possessed of a fort. Long. 85. E. Lat. 26. 16. N.

TURKIN, a small town of Asiatic Russia, in the government of the Caucasus, on the Caspian, 140 miles S. of Astracan.

TURN-AGAIN, a low, flat, and swampy island in Torres Strait, about three miles in length. It is surrounded with reefs, and is overrun with mangroves. Long. 140. 55. E. Lat. 9. 34. S.

TURN-AGAIN, CAPE, on the east coast of New Zealand, discovered by Captain Cook in 1769. Long. 177. 55. W. Lat. 40. 34. S.

TURNHOUT, a city of the Netherlands, in the province of South Brabant. It is the capital of an arrondissement, which extends over 518 square miles, is divided into six cantons and 48 communes, with 76,800 inhabitants. The city is in the district called the Campine, and is a place of active manufacturing industry, especially in producing thread-lace and linen goods of the best kind. It has, besides, several breweries, distilleries, bleacheries, and snuff-mills. The inhabitants are about 11,000.

TURNING, the art of giving circular and other forms to objects, by making them revolve in various manners in a machine called a lathe, and applying cutting instruments so as to produce the form required; or by making the cutting instrument revolve, when the object to be operated upon is fixed.

This art is of great antiquity, and is of immense importance to the practical mechanic. It embraces many varieties, requiring varied machinery for their proper performance, from the simple throwing wheel of the potter to the complicated and nearly automatic slide-lathe, in which, almost independent of manual dexterity, an indefinite number of copies of an article can be produced with unerring accuracy.

There is probably, in the range of mechanical operation, none susceptible of greater accuracy than the art of turning, and there is none which has so much conduced to the improvement of our machinery. The extent of the applications of this art may be learned by the four following conditions, which comprise the most important of its varieties. A knowledge of the manipulations no mere description can convey; and as, in the limits here assigned us, it would be impossible to describe all the varieties of the art, and the machines made use of, we shall content ourselves with such a selection as may appear to us to possess the greatest interest for the general reader.

1st. The article to be turned may be made to revolve round its own axis, and the cutting tool applied to its surface, so as to produce the requisite form, as in simple turning, performed in the ordinary lathe used by cabinet-turners; the more powerful lathe used for turning metal of large diameter; and the self-acting slide-lathe.

2d. The article may remain stationary, while the cutting instrument either merely revolves, or, while revolving, has at the same time some other motion given to it.

3d. The article may be made to move in some curve derived from circular motion, and the cutting tool applied as before.

4th. The article may be made to revolve, and at the same time to have a reciprocating motion in the direction of its axis, the cutting instrument being only applied, however, while the article is either in the course of its forward or backward motion, but its application not continued through both; and all these motions may be more or less combined, thus producing almost infinite variety.

The self-acting slide-lathe being the most perfect of the machines of the first class, we have preferred giving a drawing and description of it; from these, the other lathes referred to will be more easily understood than if we had described a less perfect machine. The lathe, when of large size, is generally driven by steam or other power; but when small it is driven by a treadle put in motion by the foot of the workman. The treadle acts on a cranked axle, on which is fixed a fly-wheel; and a band from the fly-wheel passes over the pulley of the mandril or spindle, to which the article to be turned is attached. This is generally the arrangement of the common lathe, which differs from the slide-lathe only in wanting the slide and its moving apparatus, which we are about to describe, and has in place of it a simple rest to work by hand.

The following figures represent the slide-lathe as constructed by Messrs Whitworth & Company of Manchester, and exhibit certain contrivances which have been patented by these gentlemen.

Fig. 1.

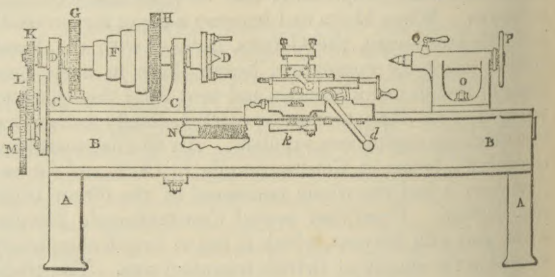

Fig. 2.

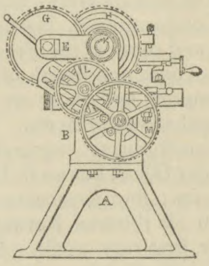

Fig. 3.

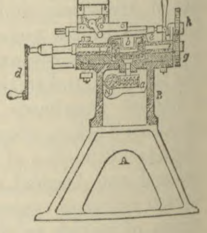

Fig. 1 is a front view; fig. 2 a view of the left-hand end; and fig. 3 a section across the lathe. The same letters refer to he same parts in all the figures. A A is a strong framing, which upports the bed of the lathe B B. At the left-hand extremity of he bed is fixed the head C C, and through steel bushes in the prights, or puppets as they are termed, the spindle or mandril) works; the projecting right hand end of the mandril is screwed, that chucks and other apparatus for holding the work to be urned may be attached to it. One of these, the double driver, will e found figured and described afterwards. In brackets projecting ackwards from the uprights another spindle E works. One of the rackets and the end of the spindle are seen in fig. 2. On the main pindle D there is a conical pulley F, carrying a pinion on its smal- r end; the pulley with its pinion turns on the spindle, but in- ependently of it. To the right of the pulley is a spur-wheel H, eyed on the spindle; to this spur-wheel the pulley can be cked at pleasure, so as to be carried round along with it. On e spindle E is a spur-wheel G and a pinion, which cannot be en in the drawing. These are fitted respectively to gear with e spur wheel and pulley-pinion of the main spindle. Different aterials require to pass the cutting tool with different degrees rapidity, in order to be efficiently operated upon. Cast iron quires to revolve slowly, so that it may come in contact with e cutting tool at the rate of about 100 feet per minute; wrought n and steel about twice as quick; and brass is better cut at a ll higher velocity. Thus, it is required that provision be made the lathe for altering the speed, independently of the velocity the prime mover. It is obvious, too, that the same material ıst require a change in the speed of the lathe, according to its ımeter, that a uniform rate of speed may be maintained by its rface. This alteration in the velocity of the spindle or mandril produced by the pulley and wheels we have just described, in e following manner:—When the belt from the prime mover, act- on the pulley F, causes it to revolve, if a slow motion be required, e pinion of the pulley is made to gear with the spur-wheel I the spindle E; and the pinion fixed on the same spindle gear- into the spur-wheel H of the main spindle D, causes it to volve with a motion slow as compared with the speed of the lley. If a higher velocity be required, the wheel and pinion the spindle E are put out of gear with the pinion and wheel of e main spindle by sliding the spindle E a little to the left hand, d then locking together the pulley and spur-wheel H, so as to ıse the main spindle to turn directly by the pulley.

The face of the spur-wheel H has drawn on it a great number of ncentric circles. The circumference of each circle is divided into ıal parts, and such numbers are chosen for the division as are mul- les of the greatest variety of measures; at each division of the cles there is pierced a hole, into which a point is pressed by pring. By means of this apparatus, an object in the lathe can ve its surface divided into any number of equal parts. On the l of the main spindle is fixed a pinion K, which, by the inter- ntion of the stud-wheels and pinion L, drives the spur-wheel fixed on the end of a screw N, which extends along the whole gth of the lathe, and is called the leading screw. The ends of leading screws and main spindle are made accurately of the ne size, so that the wheels and pinions which have for differ- purposes to be fixed on them may be exchangeable. On the ht-hand side of the lathe is seen the shifting-head or puppet which is capable of being shifted along to any part of the bed, l fixed there, and which carries the centre pin. This is adjusted re nicely to its work by means of a screw turned by the eel P, and it is fixed by the clamping screw Q. The slide-rest sists of an upper and an under slide: the latter lies across the , and is moved along it lengthways by means of the leading ew. The upper slide can move at right angles to the under , and carries the cutting tools: the manner in which the es are moved by the leading screw is, in this lathe, very in- ious. From the under slide there descends a short vertical ndle, carrying on its lower extremity a peculiarly-formed ion *a*, which is constantly in gear with the leading screw. ıen the leading screw is in motion and the pinion fixed, the er serves as a nut or female screw, and the slide is moved ng the bed of the lathe to the right or to the left as the screw y be turned. On the upper end of the vertical spindle there is d a mitred wheel *b*: into this a pinion *c* works, whose spindle sses the slide, and has a handle *d* fixed to it. On the slide ing reached one or other extremity of the bed of the lathe, it may carried to the other by reversing the motion of the screw; but s more speedily done by turning the handle *d* which turns the ion *a*, and so the slide is carried along very rapidly.

The upper slide is moved across the bed of the lathe as follows: inion *e*, which works into the mitred wheel of the vertical ndle, is fixed on the end of a shaft *f*, on whose other end is d the wheel *g*; this gears into another wheel *h*, fixed on the l of a leading screw, which crosses the main leading screw, and, means of an apparatus similar to that above described, causes the upper slide to move at right angles to the under one. In fig. 3 the under slide is represented as fixed in its position by means of a clamp, whose handle is seen at *k* in fig. 1, and the main leading screw is, by means of the pinion *a*, the mitred wheel *b*, and the pinion and wheels *e*, *g*, *h*, working the cross leading screw of the upper slide, by which it is moved across the bed of the lathe.

In plain cylindrical turning, the motion of the slide is so adjusted in relation to the motion of the article operated upon, that the cutter carried by the slide shall not move over a space greater than the breadth of its point in the time that the article makes one revolution. In screw-turning, the cutter again is made to travel over a space as much greater than the breadth of its point during one revolution of the spindle, as the pitch of the screw requires. The requisite changes in the motion are effected by changing the wheels on the ends of the main spindle and the leading screw.

Fig. 4.

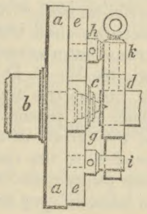

Fig. 5.

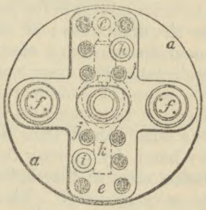


On the mandril nose there is represented, in fig. 1, what is called a double driver, and we here give the details of an excellent apparatus of this kind, invented by Mr Joseph Clement of London, by which an article can be fixed perfectly true between the centres of the lathe. The figures and description are from the Transactions of the Society of Arts of London, vol. xlvii.

"Fig. 4 is a side or edge view of the chuck; and fig. 5 is a face or front view. The same letters refer to the same part in both views.

"*a a* is a circular plate or chuck, on the back of which is formed a boss *b*: the boss *b* contains a female screw for screwing it on the nose of the lathe-mandril. On the face of the chuck or plate *a a*, and in the middle, is screwed a conical centre *c*, on which is supported one end of the thing to be turned, as shewn at *d* in fig. 4. *e e* is a parallel plate in the form of a cross, one side of which is fitted to the face of the chuck *a a*; in the middle of the horizontal arms of the plate *c e* are two oblong holes *ff*, as represented by the dotted lines in fig. 5; *g g* are two screws which pass through the holes *ff*, and screw into the face of the chuck *a a*; the necks of the screws *g g* are made to fit the holes *ff* in one direction, but the plate *e e* is at liberty to slide to and fro beneath the heads of the screws *g g* in the contrary direction: there are also thin washers beneath the heads of the screws *g g*, which act as springs, and tend to hold the plate *e e* in the situation wherever it may be slid to; there is also an oblong hole in the middle of the plate *c e*, through which projects the centre *c*: in the vertical arms of the cross or plate *e e* are six screwed holes; *h* and *i* are two studs or drivers, which may be screwed into any of the holes marked *j*, so as to accommodate the length of the ends of the carrier *k*. There is a face view of the carrier *k*, represented in its place (by dotted lines on the face of the plate, *e e*, fig. 5). The ends of the carrier are acting against the studs *h* and *i*.

"Supposing a piece of metal *d*, to be supported between the centre *c* of the chuck *a a* and the centre of the puppet-head of the lathe, and the carrier *k* to be fixed on one end of it, as shewn in fig. 4: let the plate *e e* (see fig, 5) be slid on the face of the chuck *a a*, a little towards the left hand; then the stud *h* will cause the upper end of the carrier *k* to move or turn in the same direction upon the centre *c*. But the stud *i*, and the lower end of the carrier *k*, will be moved in contrary directions, and will be separated from each other double the distance that the plate *e e* has slid on the face of the chuck *a a*; therefore, should the plate *c e* be in the above position, and the lathe put in motion, so as to turn the plate *a a* round towards the left hand, the stud or driver *h* would be the first that would come in contact with the carrier *k*. But when the turning-tool is applied to the thing to be turned, or any resistance which tends to prevent it from turning round, the carrier *k* will cause the upper stud *h* and the plate *e e*, together with the stud *i*, to be slid towards the left hand till the stud *i* comes in contact with tho lower end of the carrier *k*; then the studs or drivers *h* and *i* will be acting with equal force against the ends of the carrier *k*, which will remove the greatest part of the twist or strain from the centre *c* of the chuck *a a*, by which means any slender cylinder, &c. may be turned more perfectly than can be done by a single driver. If another stud be screwed into one of the holes opposite the drivers *h* or *i*, it will prevent the thing to be turned from overrunning itself, or back-lashing, when it has got a heavy side. The drivers *h* and *i* may be made of different lengths, as may be found most convenient."

When it is required to replace in the lathe an article whose centres have been lost, a simple apparatus, called a boring collar, is made use of. It consists of a puppet, capable of being fixed on the bed of the lathe, in the same manner as the puppet O, fig. 1, and as a substitute for it. On the right-hand side of this is fixed, by a bolt through its centre, a disc of cast iron, which has been turned perfectly flat, and which is of as large diameter as the height of the puppet above the bed will admit. On this disc a circle is traced, the highest point of it being exactly level with the centre of the mandril; and all round the circle are bored holes, varying in their dimensions, to suit the different sizes of the objects which require to be centred. The disc moving round on the bolt by which it is attached to the puppet, the hole suitable for the article to be centred is turned uppermost, so as to be on a line with the mandril, and the disc is then fixed in that position by another bolt or pin, which is passed into a hole in the puppet below the centre, through one of another inner series of holes in the plate, which correspond to those above described.

The slide-lathe which we have described is one well adapted for the machinist; but for particular uses, certain modifications are made in the apparatus: of these we shall immediately speak. In the mean time we may observe, that a very useful arrangement of the slide-lathe has been made by Mr C. D. May of Edinburgh. In his lathe the slide works, not on the top of the bed, but along its face: it thus can pass from end to end clear of the puppets, and the lathe can at once be converted into an ordinary one to work by hand, by moving the slide to the right-hand extremity of the lathe, clear of the shifting puppet, and applying the ordinary rest to work by hand. This lathe is very neat, is simple in construction, and occupies little space.

The modifications in the slide-rest are as follows: The upper slide, in place of being able to move at right angles only to the lower rest, may have other motions given to it. It may be made to turn round on a centre, and, by an index and graduated arc, may be set at any angle to the axis of the mandril. In this way it is used for turning conical work. The rest may be made, too, to receive cutting instruments, to which circular motion may be given, while the article operated upon remains stationary, as mentioned in the second division of the subject.

Drilling apparatus.

In this case a frame is added to the lathe, consisting of two uprights, one at each end, carrying a series of pulleys put in motion by belts from the fly-wheel, and which again, by means of a band, give motion to a pulley fixed on the end of a revolving cutter, carried by the slide. It will at once be seen, that when an article is held in a chuck on the end of the mandril, and turned round, so as, by means of the divided circles on the spur-wheel face, to present any number of sides to the action of the revolving cutter, and when the cutter itself can, by means of the double slides and turning motion, be set in almost any position relative to the work, the variety of uses of which this arrangement is susceptible is almost infinite. Holes may be bored with it radiating from the axis of a cylinder, as for the spokes of a wheel: they may be bored in a straight line, or in a helical line; continuous grooves may be formed in any direction. By using proper cutters, any of the geometrical solids may be formed in the lathe. A very obvious application of this apparatus is to the cutting of the teeth of wheels, either direct or oblique. Suppose that it is required to cut a wheel of ninety teeth: a circle in the dividing plate on the face of the spur-wheel, containing ninety holes, or any multiple of that number, is selected, and the spring pointer being fixed in the first hole, a proper cutter, fixed on a vertical spindle, is made to act on the wheel, and to cut out the first tooth to the proper depth: it is then withdrawn, and the mandril is turned round until the pointer falls into the second hole of the dividing plate; the cutter is again applied for the second tooth, and so on successively for all of them. In what we have described we have supposed the work to be fixed to the mandril of the lathe, and the cutting instruments attached to the slide; but the case may be reversed, and thence arises a new variety of applications. A circular saw being fixed on the mandril, an article held in the slide-rest may be presented to it, so as to be cut in any plane. Large drills, too, may be carried by the mandril, and the work to be bored fixed to the slide.

Rosette turning.

To the other varieties of the art the term of ornamental turning or engine-turning is generally applied. Among these are rosette turning, eccentric turning, elliptic turning, epicycloidal turning, and spiral turning. The lathe for the first of these has this peculiarity. The head on the left, in place of being fixed firm on the bed, stands between centres parallel to the spindle at the level of the bed. It is kept in its proper position by the adjusted pressure of four springs, one of which is fixed at each side of the front and back puppet. On the spindles are fixed the rosettes, from which the lathe derives its peculiar motion. These rosettes consist of wheels, discs, or portions of cylinders, having their surface indented in various forms. Fixed parallel to the spindle, but at a lower level, is the bar on which the rubbing apparatus is fixed; the rubber, being placed in contact with one of the rosettes, and incapable of yielding to the inequalities of its surface, forces the spindle on which the rosettes are placed, and consequently the article operated on, to move in various regular curves, as the indentations on the rosette guide them. The rosette may be applied to elliptical turning by using a proper chuck, as described under that head. For vertical waved lines, a pinion is fixed on the head of the spindle, working a rack attached to a vertical slide fixed in the front puppet; to counterbalance the slide, a cord is attached to its top, passed over a pulley above, and attached to a weight at its other extremity; thus the pinion is relieved from unnecessary friction.

In eccentric turning, an eccentric chuck is used. This consists of a solid circular plate, which is fixed to the mandril of the lathe. On the face of the plate are fixed two guides, so as to form a dovetailed slide for another plate, which is moved by a screw sunk in a slot in the under plate. On the upper plate is a circular toothed plate, which is capable of being turned round its centre, and is retained in any position by a catch, which falls between its teeth, and is held by a spring. On the centre of this wheel is fixed a screw similar to that on the nose of the mandril, and to this is chucked the work to be turned. The first plate moves, of course, concentric with the spindle of the lathe; but the slide, with its circular plate, can be moved so that the work revolves with any degree of eccentricity required.

Epicycloidal turning is another beautiful variety of the art. Like eccentric turning, this is performed by a chuck peculiarly formed, but so complicated as to be totally unintelligible without the aid of numerous figures; we are under the necessity, therefore, of referring the reader to the works quoted at the end of the article for a full explanation of it. In Bergeron's work, he will find beautiful engravings of the apparatus for this and the other varieties of ornamental turning, with minute descriptions.

Elliptic turning will be found described under that title.

The lathe for spiral turning is constructed as follows. On a shaft lying above the bed are three drums, or large wheels, with broad rims, that on the extreme left being smaller than the other two. To the circumference of the latter is attached a cord, which is stretched tight to the end of a strong elastic beam or spring fixed at the roof. On the bed, beneath this drum, is the fixed head, which consists of two puppets fixed at about two and a half feet asunder. In the top of each puppet is fixed a brass bush, in which the spindle, which is perfectly cylindrical, moves as directed by the leading screw, consisting of a cylinder of wood, firmly fixed on the spindle between the two puppets, on which is grooved out a screw of the same pitch as that required to be made. This is effected by placing beneath, and close to the cylinder, a wheel having a thin, round, or pointed edge, and turning on centres in a forked frame, after the manner of a framed pulley. The frame of this wheel is fixed on a stiff centre, so as to be capable of being set to any angle. If the spindle be then caused to revolve, it will also move in a longitudinal direction, in exact proportion to the divergence from a right angle, at which the wheel is set, and there will be traced on the cylinder a screw, which, when cut to fit the edge of the wheel, is a leading screw. These leading screws may be multiplied indefinitely, by shifting the wheel to different angles, to mark any number of cylinders or leading screws that may be required. On the spindle at the front of the leading screw is a wooden pulley, round which passes the cord which comes down from the large drum on the left; it then passes down and is fixed to the left corner of the treadle, the other end of which is raised by a cord passing straight from its extremity to the large drum on the other end of the shaft. By pressing down the treadle, the cord, which, as before remarked, passes round the pulley on the spindle, causes it to revolve; it also, by unwinding from the drums, causes them and their shaft to revolve, and the smaller drum, as it revolves, warps round it the cord attached to the spring in the roof, thereby bending it. It is evident that, whenever the pressure of the foot on the treadle is removed, the elasticity of the spring will cause it to pull off the cord which held it down, and cause the small drum round which the cord was wound, and the other drums, and the spindle, to revolve in the opposite direction to that caused by the descent of the treadle.

The shifting head consists of two puppets and a spindle, the same as that just described for the fixed head. Solid on the head of each spindle is a socket or hollow cylinder, in which is fixed, by means of a side-screw or otherwise, a strong taper screw: one of these screws is inserted into each end of the piece of wood to be turned. The rest has a groove, through which the tool passes, in order to prevent the longitudinal motion from displacing it. It is evident that no more length of twisted work can be produced at once than the length of the leading screw; but by shifting the rest, and taking care that the cuts join accurately, the twist or

ron
ay
‖
rtle
nd.

screw may be continued to any desired length. By means of this athe, every variety of twisted work can be produced.

The reciprocating motion of the spindle may be varied by the ntroduction of other apparatus for its introduction than the screw ve have described. By means of elliptical or other rubbers placed t the extremity of the spindle, singular compound motions are roduced; and when with these are combined rubbers to cause teral motion, as in the rosette lathe, an immense variety of eautiful and fanciful figures is the result.

For full information on lathes and turning, the reader may con- ılt the Transactions of the various societies, and the following orks: L'Art de Tourner, par Charles Plumier, Lyons, 1701: 'Art de Tourner, par Paulin Desormeux, Paris, 1824; Manuel ı Tourneur, par Bergeron, Paris, 1816; Ibbetson's Specimens Eccentric Circular Turning.

TURON Bay, a fine bay of Cochin-China, on which is uated Faifo, the capital and principal seat of commerce the country. The adjacent district is remarkably fer- e and beautiful. The channel into this bay is round the rth-east end of the Hansan peninsula, having an island the north. All the coast is safe to approach, the water oaling gradually from twenty to seven fathoms. Cape uron, in long. 108° 15′ east, and lat. 16° 5′ north, forms its stern extremity, in which Turon Island, situated six miles the north, makes an excellent harbour, where vessels are eltered from all winds. At the southern extremity of this rbour is the mouth of the river which leads to the city of uron. It is about 200 yards wide, with about two fathoms pth. The town of Turon stands about a mile above the outh of the river, and, as well as the peninsula, harbour, d river, is named by the natives Hansan. The houses ich it contains are low, and mostly built of bamboos. The ins of some better houses are still visible. The port was an- ently the chief mart for the trade of Cochin-China with e Chinese empire and Japan; but prior to 1793, when was visited by Lord Macartney, the city of Turon had fered greatly by civil wars, and was surrounded by ex- nsive masses of ruins. The vessels that resort thither either junks from different parts of China, or craft be- ging to the Portuguese of Macao.

TURPENTINE, a transparent viscous substance, flow- i either naturally or by incision from several resinous t es.

TURRIFF, a small but thriving and industrious town i Aberdeenshire. It is pleasantly situated on a gentle ent on the right bank of a branch of the river Deveron, t rty-four and a half miles from Aberdeen. It was erected i o a free borough of barony in the year 1511, by James I. This town possesses manufactures of linen yarn, thread, l brown linen; and there is also a large bleachfield. In lition to the fine old parish church, which is not now d, there is a new and handsome one. There is also an scopal chapel; and the earl of Errol has endowed a free ool. The population amounted in 1821 to 750, and in 31 to 1136.

TURSHEEZ, a considerable city of Persia, in the pro- ce of Khorassan, situated on the verge of the Salt De- t. There is an old city, Sultanabad, which is small; a new one has been added, in which the governor and principal officers reside; and the two cities contain ut 20,000 inhabitants, among whom are 100 Hindu ilies. The chief imports are indigo and other drugs m the west, and wool, cloth, and rice from Herat. The ef export is iron. The small quantity of European ds which are used is brought from Mazanderan. Tur- ez is 160 miles west-north-west of Herat. The inter- ing country is wild, mountainous, and uncultivated.

TURTLE Island, a small island in the Eastern Seas. ng. 132. 51. E. Lat. 6. 35. S. Of the same name, there another small island in the South Pacific Ocean, sur- nded by a reef of coral rocks. Long. 177. 57. W. Lat. 50. S. There is a cape of this name on the south coast he island of Jáva. Long. 109. 58. E. Lat. 7. 42. S.

Turuchansk
‖
Tuscany.

TURUCHANSK, or Mangasea, a town of Asiatic Russia, on the Yenisei, the smallest and most northerly of all the Siberian towns which bear the name of a city. It derives its name Mangasea from a magazine having been originally built, in 1601, for the collection of the furs paid in tribute to Russia. It was removed from the river Taz, where it was first placed, to the mouth of the Turuchan, and received the name of that river. The houses do not amount to more than 100, and are built in the most scattered manner. The principal part of the town consists in a little fort built of wood, and defended by four small pieces of artillery. The trade consists entirely in furs, which are exchanged for all sorts of merchandise. Most of the inhabitants are Cossacs, whose services are required to overawe the wild inhabitants of the neighbouring regions. The ground is barren, but the water-fowl in summer are innumerable. Long. 88. 44. E. Lat. 65. 40. N. The river Turuchan, on which the above town is situated, rises in the district of Turuchansk, and after a course of 200 miles, falls into the Yenisei near Turuchansk.

TUSCAN Order, in *Architecture*. See Architecture.

TUSCANY, a grand duchy in Italy, said to have derived the name from a King Tuscus, who in remote ages ruled Etruria. It extends in north latitude from 42° 5′ 20″ to 44° 31′ 10″, and in east longitude from 9° 32′ 25″ to 11° 4′ 35″. It is bounded on the north-west by Lucca and Modena; on the north-east, east, and south-east, by the states of the church; and on the south-west and west by the Mediterranean Sea. Besides what is contained within these boundaries, its territory includes, on the north, the vicariate of Pietra Santa, surrounded by the dominions of Modena, Parma, Genoa, and Lucca. It also possesses the islands of Elba, Pianosa, Palmajola, Gorgona, Giglio, Montechristo, Melora, Formiche, and Gianuti. It comprehends 8494 square miles, or about 5,500,000 acres. It is divided into five departments:

Departments.	Cities.	Towns.	Villages.	Inhabitants.
Florence	12	55	958	596,258
Pisa	5	19	537	295,649
Sienna	6	22	212	128,095
Aretino	10	32	596	201,292
Groseto	3	6	187	53,736
	36	134	2517	1,275,030

By a later enumeration, in 1833, the whole number of inhabitants was found to be 1,320,500. They all adhere to the Roman Catholic church, with the exception of 9300 Jews, mostly in Leghorn, who are fully tolerated, and a few German, English, and other Protestants, in the commercial places. The ecclesiastical establishment is numerous and expensive, there being three archbishops, 16 bishops, and 10,000 secular clergy, with 96 monasteries and 67 nunneries, whose members are 6750. The whole revenue of the church, including the regular and the secular, is estimated to amount to a very large sum.

The cities of Tuscany, of more than 10,000 inhabitants, are the following:

Cities.	Population.	Cities.	Population.
Florence	78,900	Pisa	20,000
Leghorn	50,550	Patro	10,000
Sienna	24,500		

Face of the country.

The Apennine Mountains cover about one third of the duchy, entering it at the north-west part, and extending into the papal dominions, throwing out various branches. The loftiest points of the range are the Boscolengo, 4178 feet in height; the top of Vernina, 3914 feet; the top of Sasso-Eismore, 3798 feet; and Monte Raticosa del Pietramala, 2719 feet. The Vale of Arno, which comprehends one sixth of the duchy, is a basin formed by the mountains;

Tuscany. and of this vale Florence is nearly in the centre. While the upper part is narrow, its breadth extends as it approaches the sea, where it forms a wide and level plain, highly unfavourable to the health of the inhabitants. This district, however, called the Maremma, is very fruitful in grass, and feeds abundance of cattle. The river Arno, the chief stream, which receives most of the others, is navigable for boats to Florence; but its chief utility is of a very different kind, and it is diverted into hundreds of channels, for the purpose of watering the fields and gardens. The climate is as different as the face of the country. The Vale of Arno, which includes most of the department of Florence, though only one fourth of the extent, contains half the inhabitants of the duchy, and is generally healthy, and the weather mild. On the mountains the snow lies many weeks, and the cold is severe. In the marshy districts, which comprehend nearly one half of the extent, the fevers are constant, and it is only in winter that the herdsmen are induced to resort to them.

Agriculture. In the Vale of Arno the land is admirably cultivated. It is commonly divided into small tenements, from four to ten acres each; eight or ten of which combine to keep a team of oxen among them, and each has commonly a small horse and some cows, besides a few calves. They are on the Metayer system, paying rent by a portion (commonly one half) of the produce. The corn chiefly consists of wheat, but barley and oats are extensively grown on the Apennines; in some parts a large quantity of maize, and in others of rice; and besides these, pease and beans of various kinds. Chestnuts are used as a substitute for bread by the greater part of the rural inhabitants. From 800,000 to 1,000,000 bushels of this food are computed to be annually obtained and consumed. In years of average productiveness, the corn raised is about equal to the consumption; but in deficient seasons, wheat is required, which Leghorn can commonly supply by importations from the Black Sea and the Sea of Azoph. The unhealthy marshes feed about 400,000 sheep, 30,000 horses, and a multitude of cows and goats. Fruits are abundant, and citrons, pomegranates, figs, and almonds are articles of export. An ample supply of culinary vegetables is always raised. Large quantities of both red and white wine are made; and though not much esteemed by foreigners, some of the best of the former is exported, mostly in flasks. Olive oil is an extensive object of industry. Much of it is converted into soap or consumed at home; but that of the best quality is exported to distant countries, it is said to the amount of more than 700,000 gallons. The whole of the silk produced does not exceed 200,000 pounds weight, and it is all consumed at home in manufactures. Some flax is raised; but that used for making the finest linen is imported from foreign countries. The breed of sheep has been of late years increased by crosses with Merinos, and now the wool is of moderate fineness. The greater part is used at home, but some portion is exported.

Fisheries. The fisheries are carried on extensively on the shores of the continent, as well as from the islands. The tunny fishery has establishments in and near Leghorn and in Elba; while that for anchovies is conducted chiefly from the islands, particularly from Gorgona, the celebrity of whose curing is known in all parts of the world.

Manufactures and trade. There is a variety of manufactures, but they are chiefly carried on at Florence or Leghorn. One which employs many hands, that of straw-plait for hats, is indeed dispersed in all the villages. Cloth of linen and woollen, silks of different kinds, hosiery, hats, and carpets, and some ironmongery, are made for home use. The chief manufacture for foreign trade is paper, which employs 80 mills. There are skilful makers of soap, perfumery, essences, porcelain, coral articles, lamps, glass, alum, vitriol, Florentine wax, marble and alabaster figures, and carriages. These, with the products of agriculture, form the trade of Leghorn, and enable the duchy to procure from foreign countries the several articles which they need. Tutic

Reve and e diture The revenues of the duchy arise partly from a land-tax, partly from taxes on exports, from stamps, from a lottery, from farming tobacco, from the mines and salt-works, and the public domains. They amount to 16,000,000 francs. The expenditure, which is 100,000 francs less, defrays the communal and departmental expense of the poor, of hospitals, bridges, and roads, as well as of the military, civil, and judicial departments. The national debt is in a gradual course of extinction, having, since the peace, been reduced from L.5,000,000 to L.1,500,000 sterling. The army consists of 5500 men, besides a militia, which can be called out when it is wanted. The naval force is three corvettes and two gun-boats.

Gove ment The government is an hereditary unmixed monarchy, in a junior branch of the imperial house of Austria; and after the death of Maria Louisa, the widow of Bonaparte, the duchy of Lucca will be united with Tuscany.

Hist After the fall of the western Roman empire, in 476, the Ostrogoths obtained dominion over Tuscany. They were succeeded by the Greeks for a short time, and afterwards by the Lombards. It then assumed its present name, having before been generally called Etruria; and was constituted a feudal dukedom under the supreme government of the kings of Lombardy. When Charlemagne established his empire, Tuscany was ruled as one of its provinces. Under Louis the Pious, it was divided into several districts, under the authority of nobles appointed by him. Some of these called themselves margraves and some dukes, but all of them managed to render the dignity hereditary in their several families. In 1160 the emperor Frederick the First obtained the whole of Tuscany by purchase from the Guelphs, who were then dukes of Bavaria. The cities on this occasion strove to obtain independence. Florence, the capital, which assumed the lead, combined with several other cities against the authority of the empire; but Pisa, with a few other cities, adhered to that authority, and in 1197 formed a league to maintain it. These opposite leagues gave rise to civil wars between the two parties called the Guelphs and Gibbelines, by which Tuscany was wasted during nearly 300 years. Sienna had become an independent and flourishing state from the middle of the thirteenth century, but the theatre of contests between the nobles and the citizens. Similar contests arose in Florence, where the family of the Medici, who had gained vast wealth by trade chiefly with the eastern countries, obtained the supreme authority in 1434, and maintained it during three centuries. Florence subdued Pisa in 1509, and Sienna in 1557. This was the period when Florence established itself as the nurse of literature and of the fine arts, and collected within its territory the greatest men of the age. Tuscany continued under the power of the family of the Medici till 1737, with the name of a dukedom. Giovanni Gasto de' Medici then dying without heirs, was, in consequence of a settlement by Cosmo de' Medici in 1569, succeeded by Francis duke of Lorraine, who afterwards became emperor of Germany. Tuscany was then governed by the house of Austria, till, in the revolutionary war of France, it was seized by that power, and received from Bonaparte the rank of a kingdom, with its ancient name Etruria. This settlement was but temporary, to favour a delusive agreement with the king of Spain, whose daughter was promised the sovereignty; and at length, when Bonaparte fell, it was restored to the family of Austria, who continue to rule it. Tuscany has been celebrated for the illustrious men which it has produced, particularly, besides the Medici, Dante, Petrarca, Galileo, Macchiavelli, Leonardo da Vinci, and Michel Angelo.

TUTICORIN, a town of Hindustan, on the sea-coast f the province Tinnevelly, where is a pearl fishery, though ie pearls are not so valuable as those found on the sea-oast of Ceylon, in the bay of Condatchy, being stained ith a blue or greenish tinge. Here the Dutch formerly ad a factory. It was taken from them during the last ar, and was restored in 1818. Long. 78. 23. E. Lat. 54. N.

TUTOR, in *Law*, is one chosen to look to the persons id estates of children left by their fathers and mothers in eir minority.

TUZLA, a town of Caramania, in Asiatic Turkey, situated an elevated plain in the interior, at the western extreity of a chain of salt-lakes, twenty-eight miles north of onieh.

TWEED, the fourth river in Scotland for size, and the undary between England and Scotland, from Carham burn, its south side, six miles above Coldstream, till it falls to the German Ocean at Berwick. It takes its rise in the per part of the parish of Tweedsmuir, in the county of ebles, at the foot of a hill called Tweed Well, and flows a north-easterly direction, having its waters augmented the numerous small streams which descend from this hilly strict. Three miles above Peebles it is joined by the me, which issues from the confines of Edinburghshire; d here it takes an easterly bend, which it maintains durg the rest of its course. Two miles farther down it ceives the Manor, and at Peebles the Eddlestone. By ese accessions it is now a considerable stream; and alough only thirty miles from its source, it has in that disce fallen 1000 feet, being two thirds of its descent in a urse from eighty-five to ninety miles. In its progress wards Selkirkshire, it receives additional strength from e Yair and the Leithen. It is next joined on the right the united waters of the Yarrow and the Ettrick; and, er passing Abbotsford, it receives the Gala on the left, d enters Roxburghshire. During its progress to Kelso, passes the celebrated ruins of Melrose Abbey, as well those of Dryburgh, in which are deposited the remains Sir Walter Scott. The Leader falls into it below Dryange, and is the only stream which it receives till it is ited to that of the Teviot. From the volume of water ded by the Teviot, the Tweed is almost doubled in size; d as it flows majestically down Berwickshire, it receives its way the waters of the Eden, four miles on the left m Kelso; the Leet at Coldstream; and the sluggish Till m the English side, three miles below Coldstream. om these accessions its increase is again perceptible. ter passing the ruins of Norham Castle, it flows for seral miles through a rich and highly-cultivated district, ceiving the large stream of Whitadder on the left; and ssing the ancient town of Berwick on the same side, discharges itself into the German Ocean. The distance m Peebles to Berwick is nearly sixty miles, yet its deent in that distance is only 500 feet. It is computed to ain in its course 1870 square miles. This river is of no nsequence in a commercial view. It is principally famed the rural scenery through which it flows, for the imrtance in which it was formerly held as being in part the undary between the two kingdoms, and for the associans with which it is connected in Scotish song. From source to where it enters the ocean, the whole run is nominated the Vale of the Tweed.

TWEEDDALE, or PEEBLES, a county in the south of otland. See PEEBLESSHIRE.

TWENTY-FOUR PERGUNNAHS, a small district in the ovince of Bengal, situated chiefly to the south of Caltta, on the east side of the Hooghly. This was the first ritory of any extent possessed by the British in Bengal. was ceded to them by the nabob Jaffier Aly Khan, immetely after the revolution of 1757, to which was afterwards ded Lord Clive's Jaghier. It comprehends about 882 miles of superficial extent, and constitutes one of the Bengal collectorships. Since it was occupied by the British, it has progressively improved in population, cultivation, and commerce. A great quantity of waste land has been brought into cultivation, and a number of temples and other buildings has been constructed. Within its boundaries, 190 seminaries, maintained from the produce of certain charity lands, and from voluntary contributions, have been instituted. The inhabitants may be estimated at 1,625,000, and the Hindus are in the proportion of three to one. Adding the population of Calcutta, 600,000, the total will amount to 2,225,000.

TWENTY-FOUR RAJAHS, a large district of Northern Hindustan, situated between the 28th and 30th degrees of N. lat., and divided into twenty-four petty principalities, the whole of which are tributary to the government of Nepaul. Respecting these states little is known except their names.

TWENTY-TWO RAJAHS, a district in Northern Hindustan, tributary to the Nepaulese, and divided into twenty-two petty principalities.

TWELFTH-DAY, the festival of the Epiphany, or the manifestation of Christ to the Gentiles; so called, as being the twelfth day, exclusive, from the festival of Christmas.

TWER, a city of Russia, in the province of Moscow, the capital of a stadtholderate of the same name, which is 26,010 miles in extent, and contains a population of 1,270,000 persons. The city is on the right bank of the Wolga, where the waters of the Twerza and the Tmaka fall into it. Twer has no fortifications, but is surrounded with palisades. There is a citadel, in which is a palace with elegant gardens, belonging to the emperor. The city is laid out in regular streets, but the high street alone consists solely of stone houses, and most of the others are of wood. There are a cathedral and other twenty-eight churches, with two monasteries. The quays along the banks of the Wolga are very fine, and the whole is extensive; but many parts of the city are still unoccupied by buildings. It is a place of considerable trade. The inhabitants make nails and other ironmongery, much linen both of flax and hemp, a great quantity of stockings, cables, ropes, and twine, besides making oil and leather, and melting tallow for exportation The Wolga is the great pathway of its productions. The city contains 24,800 inhabitants. It is 376 miles distant from St Petersburg, in longitude 35. 52. 16. E. and latitude 56.51. 44. N.

TWICKENHAM, a parish of the hundred of Isleworth and county of Middlesex, ten miles from London. It lies on the river Thames, opposite to Richmond, with which it is connected by an elegant bridge. It is remarkable as the residence of Pope, who was buried in the parish church, and for Strawberry Hill, the elegant dwelling of Horace Walpole. There are many other distinguished private houses within the parish. The population amounted in 1821 to 4206, and in 1831 to 4571.

TWILIGHT, that light, whether in the morning before sunrise, or in the evening after sunset, supposed to begin and end when the least stars that can be seen by the naked eye cease or begin to appear.

TWINS, two small islands in the Eastern Seas, near the north coast of the island of Flores. Long. 122. 33. E. Lat. 8. 2. S.

TWO BROTHERS, two small islands in the Eastern Seas, near the west coast of Borneo. Long. 109. 13. E. Lat. 1. 32. S. Other two islands, twenty-seven miles from the east point of the island of Madura. Long. 114. 43. E. Lat. 6. 50. S. Other two near the west coast of the island of Celebes. Long. 119. 22. E. Lat. 4. 40. S.

TWO-HEADED POINT, a cape on the south-west coast of the island of Kodiak. Long. 207. 5. E. Lat. 56. 54. N.

TWO HILLS, a small island among the New Hebrides, in the South Pacific Ocean. Long. 160. 38. E. Lat. 17. 15. S.

TWO SISTERS, two small islands in the Eastern Seas, covered with wood, and surrounded by a reef of coral rocks. Long. 106. 12. E. Lat. 5. S.

TYGERS' ISLANDS, a cluster of small islands and shoals in the Eastern Seas, thirty miles east from the island of Saleyer. A small island in the Chinese Seas, near the coast of Chiampa. Long. 107. 45. E. Lat. 40. 47. N. Another small island in the Chinese Seas, near the coast of Cochin-China. Long. 106. 13. E. Lat. 16. 51. N.

TYNDALE, WILLIAM, a learned and pious martyr, was born during the latter part of the fifteenth century. He is said, but apparently without foundation, to have been the grandson of Hugh, Lord Tyndale; who having been engaged in the civil wars between the houses of York and Lancaster, lost his honours, together with his estate in Northumberland, and, under the borrowed name of Hutchins, sought a place of refuge in Gloucestershire, where he retrieved his fortune by marrying the daughter and sole heiress of Hunt of Hunt's Court. William Tyndale having been early and well initiated in learning, was sent to Oxford, where he was entered of Magdalen Hall. He not only acquired a knowledge of the Latin, but even of the Greek language, which at that period was but little understood in England. He read the Greek Testament to the students of Magdalen College as well as Magdalen Hall. After having taken his degree in arts, he is said to have passed some time in the university of Cambridge. On the 11th of March 1502, deacon's orders were conferred upon him by a suffragan of Warham bishop of London, in the church belonging to the priory of St Bartholomew in Smithfield. He was ordained priest to the nunnery of Lambley, in the diocese of Carlisle; and in 1508 he became a friar in the monastery of the Minorites at Greenwich. Even at this period of his life, he appears to have been impressed with the great importance of presenting to the people the sacred Scriptures in their mother tongue; and he had commenced his version of the New Testament so early as the year 1502. He was afterwards engaged as a tutor and chaplain in the family of Sir John Welch, a knight of Gloucestershire, who kept a hospitable table, and was frequently visited by the neighbouring prelates and other clergy. The careful and anxious study of the New Testament had prepared Tyndale for receiving the doctrines of the reformation. As he found it unsafe to prosecute his pious labours in his own country, he sailed for Hamburg in 1523, and from that port proceeded to Wittemberg, at that time the residence of Luther. There he completed his version of the New Testament. John Fryth and William Roy, who both suffered martyrdom, lent their aid as his amanuenses. "One edition," says Mr Offor, "probably of three thousand, was prepared for general circulation: this was quickly followed by a more elegant edition in quarto, with glosses, commenced at Cologne in 1526, and finished at Worms or Wittemberg. The type, cuts, and ornaments of both these books are those used by the German printers on the Rhine." This version has recently been reprinted under the superintendence of Mr Offor, who has prefixed a memoir of his life and writings. Lond. 1836, 8vo. He likewise undertook a translation of the Old Testament, and having completed his version of the first books in 1529, he began to publish them in separate tracts, ornamented with wood-cuts, and accompanied with notes, which gave no small offence to the bigoted clergy. Having completed the last book of the Pentateuch, he sailed for Hamburg with the view of printing it; but being wrecked on the coast of Holland, he lost his money, his books, and manuscript. He however continued his journey, and being joined by Coverdale, they again translated the book of Deuteronomy, and, with the assistance of a pious lady named Van Emmerson, printed it in the year 1530. He afterwards translated the book of Jonah. The circulation of the Scriptures in the vulgar tongue excited the utmost alarm in England, where many copies of his version of the New Testament were committed to the flames. The king, the cardinal, and the chancellor, made some ineffectual attempts to induce him to return home. He afterwards fixed his residence at Antwerp; and there one of their emissaries, a miscreant named Henry Phillips, circumvented the worthy and unsuspecting man; and having procured a warrant at Brussels, betrayed his confidence with signal baseness, and delivered him into the hands of the officers. He was committed to prison at Vilvoord, a village between Brussels and Malines. By virtue of a decree made at Augsburg, against what was termed heresy, he was condemned to suffer death; and after having been in custody about a year and a half, he was, in September 1536, conducted to a rising ground near his prison, was first strangled, and his body was then consumed by fire. Tyndale, who was a man of learning as well as talents, appears to have translated the Scriptures from the original tongues; and his pious labours gave a great impulse to the progress of reformation. Of the English language, as written at that period, his own works afford an excellent specimen. In his controversy with Sir Thomas More, he had many advantages over his antagonist. His Works, together with those of Fryth and Barnes, were collected into a large volume. Lond. 1572, fol. Dr Geddes has remarked, that although his translation is far from perfect, "yet few first translations will be found preferable to it. It is astonishing how little obsolete the language of it is, even at this day; and in point of perspicuity and noble simplicity, propriety of idiom, and purity of style, no English version has yet surpassed it."

TYNEMOUTH, a town of the ward of Castle, in the county of Northumberland, 286 miles from London. The name describes the situation. The town has considerable salt and glass works, and vast quantities of coal are shipped from the port. It has lately been visited by company for sea-bathing. Tynemouth was created a borough by the act of 1832, and now sends one member to the House of Commons. The population amounted in 1801 to 3856, in 1811 to 5834, in 1821 to 9454, and in 1831 to 10,182.

TYPE (τύπος), an impression, image, or representation of some model, which is termed the *antitype*. In this sense the word frequently occurs in the writings of divines, who employ it to denote that prefiguration of the great events of man's redemption, which they trace in the principal transactions recorded in the Old Testament.

TYPE, the stamps used in printing, for the purpose of impressing the characters upon paper. They usually consist of a right-angled shaft, with the character in relief upon the upper end; but in the general term are included the spaces, quadrats, &c. which are shafts merely without any characters, and which, being of less height than the rest, receive no ink and make no impression upon the paper.

TYPE-FOUNDING. In the article PRINTING the reader will find that the invention of the art of type-founding was a very early consequence of the discovery of the rude art of taking impressions from laboriously excised letters of wood and metal; and that after an investigation of the statements of various authors, the honour of the invention has been given to the illustrious partnership of Gutenberg, Fust, and Schœffer, the larger share being allowed to the latter, as having had practice in the design and proportioning of letters in his original employment of an illuminator; that the place of the invention was the city of Mentz, and that the time was about the year 1457. Nor, upon examination, will it appear that any other can dispute the honour with these worthies, inasmuch as they indisputably used cast metal types before e secession of Gutenberg from his associates, and conse- uently before the dispersion of their workmen by the capture Mentz in the year 1462; nor will the claims of Koster of aarlem in any case interfere with these, the most sanguine his supporters carrying his pretensions no farther than e art of taking impressions from excised characters of ood, of lead, and lastly of tin. The necessity of some provement upon the original method of forming types, en on the very limited scale upon which the first efforts typography were conducted, must be obvious, and it pears to have advanced in a natural and rapid course. he first step seems to have been the striking of a letter approved cut, answering in some degree to the modern nch, into soft clay or plaster, and the infusion of metal into e mould thus formed; the shaft or *body*, which by so rude d uncertain a method must necessarily have been rough d untrue, being dressed into correctness by manual la- ur. The art of casting and working metals, however, ing at that time by no means defective, and Fust being profession a worker in gold and silver, it is probable at a process not unlike the modern was soon invented; t of this we have no certain evidence, the whole art of inting being carefully kept a "mystery" by the initiated til about half a century after the probable date of the vention.[1] This evidence is afforded us by the device of dius Ascensius, an eminent printer of Paris and Lyon in e beginning of the sixteenth century, and also by that an English printer, Anthony Scoloker of Ippeswych, o modified and adopted the device of Ascensius, as indeed l many other printers of various countries. This curious sign exhibits in one apartment the various processes of inting, the foreground presenting a press in full work, e background on the left the cases and the compositor, d on the right the foundery; the matrix and other ap- ances bearing a precise resemblance to those at present use. This introduces to observation the fact that the rlier printers generally combined all the various processes their profession in their own offices, although it would pear, that as the art spread over Europe, and secrecy be- ne less and less necessary, the most enterprising speedily gan to furnish their distant brethren with types from their spective founderies. Thus it would appear that the first pes of the English architypographer Caxton were sup- ed by Ulric Zell, and that it was not until the establish- ent of his printing-house at Westminster that he began cut letter in imitation of his own hand-writing, and more reeable to the fashion of writing at that time in use in gland. Lettou and Machlinia are supposed to have rchased their types from foreign founderies, perhaps from on or Milan. But Wynkyn de Worde discarded that lousy which had hitherto obstructed the progress of the t in England, and having cut many founts of considera- e beauty, supplied his contemporary typographers. His ck letter in especial was so much esteemed as to have en in use to a very late period, and it is said that rem- nts of his founts are to be found in some of the most cient printing establishments; nay, it is even possible at some of his original punches or matrices might yet by iligent antiquary be discovered—a valuable and interest- addition to our many curious relics of the art.

The first record of the separation of the art of type- inding from that of printing, would appear to be a decree the star-chamber in the reign of Charles I., dated 11th ly 1637. This was probably one of the attempts to sup- ess the printing of seditious works by the rising puritans, o, after establishing secret printing-offices in various parts of the kingdom, found it necessary for secrecy to cut their founts themselves. The decree seems to have been in some degree a revival of one of the same nature, 28 Elizabeth, limiting the number of printers to twenty. By the first-mentioned decree it was ordered,

That there shall be four founders of letters for printing, and no more.

That the archbishop of Canterbury, or the bishop of London, with six other high commissioners, shall supply the places of those four as they shall become void.

That no master founder shall keep above two apprentices at one time.

That all journeymen founders be employed by the masters of the trade, and that idle journeymen be compelled to work upon pain of imprisonment, and such other punishment as the court shall think fit.

That no master founder of letters shall employ any other person in any work belonging to the casting and founding of letters than freemen or apprentices to the trade, save only in pulling off the knots of metal hanging at the end of the letters when they are first cast, in which work every master founder may employ one boy only not bound to the trade.

The four founders appointed by this decree to serve the whole kingdom were John Grismand, Thomas Wright, Arthur Nicholas, and Alexander Fifield.

This decree was revived 14th Charles II., renewed 16th Charles II., and again for seven years 1st James II., at which term it expired, and was never renewed.

The founts in use in English printing-offices may be divided into two kinds; those used for book, and those for job printing, that is, hand and posting bills, &c. Of book types there are twelve regular bodies, viz. Great Primer, English, Pica, Small Pica, Long Primer, Bourgeois, Brevier, Minion, Nonpareil, Ruby, Pearl, and Diamond. Besides these, Minion-Nonpareil is a good deal used; and some founders have introduced intermediate founts, as Emerald.

It is much to be regretted that no uniform standard has been adopted by letter-founders for their founts of the same-named letter; they vary not only from those of other founders, but even from their own, owing to which it seldom happens that any two founts *stand* together. This is the cause of much inconvenience, as in the instance of capitals and small capitals, accented letters, signs, and other sorts introduced into common matter; the printer being obliged to purchase a small quantity of each with every fount, whereas, were there any uniformity, he might have a considerable quantity to be used with any fount as occasion required.

Great Primer (Fr. *Gros Romain;* Ger. *Tertia*) is the largest type in use in book printing, being chiefly for large Bibles, on which account it is sometimes called Bible Text; but it is very seldom employed. There are about 51¼ ms to a foot: it is double the body of Bourgeois.

English (Fr. *Saint Augustin;* Ger. *Mittel*) is much used for church Bibles, and for works in folio and quarto. The French name is probably derived from its being first used to print the works of St Augustin; the German from its being the middle of seven standard founts used by the early German printers. There are about 64 ms to a foot: its body is equal to two Minions.

Pica (Fr. and Ger. *Cicero*, from its having been first used for Cicero's Epistles) is the fount which is used as the general standard of measurement in casting leads, quotations, cutting rule, and regulating the price of press-work, &c. It is in very extensive use for works of a standard character, history, art, and other library works: it is sufficiently large for weak eyes, and not too great for moderately sized 8vo pages, being in fact the just medium. There are 71 ms to a foot, and it is equal to two Nonpareils.

---

[1] A copy of the *Speculum Humanæ Salvationis*, in the library of the late duke of Marlborough, presents probably the earliest specimen of t types; twenty-five of its leaves being printed from solid wooden blocks, or perhaps from wooden blocks on which the designs have been cut that the scrolls, cut upon other blocks, were inserted in spaces left for them; while, in thirty-eight leaves, the scrolls are in cast type, serted in the designs in lieu of the engraved scrolls.

Small Pica (Fr. *Philosophie;* Ger. *Brevier*) is perhaps the most extensively used of all the founts, being a very useful and well-proportioned letter. Novels are almost always printed in this body. 83 ms to a foot; equal to two Rubies.

Long Primer (Fr. *Petit Romain;* Ger. *Corpus*) is likewise much used, being very well adapted for works in 12mo, dictionaries, and other works in which much matter is to be got into a small space: it is the type of the Waverley Novels and of this Encyclopædia. 89 ms to a foot: two Pearls.

Bourgeois (Fr. *Gaillarde;* the Germans have none to correspond) is much used for the same purposes as Long Primer, and in solid matter is difficult to distinguish by the eye from that body. 102 ms to a foot: two Diamonds.

Brevier (Fr. *Petite Texte;* Ger. *Petit* or *Jungfer*) is so called from its having been much used for printing breviaries. It is much employed for small works, and for notes. 112½ ms = 1 foot.

Minion (Fr. *Mignonne;* Ger. *Colonel*) is chiefly in use for newspaper advertisements; it is a very pretty fount, and well adapted for pocket editions, Prayer-books, and Bibles: it is perhaps the smallest of readable sizes. 128 ms = 1 foot: half English.

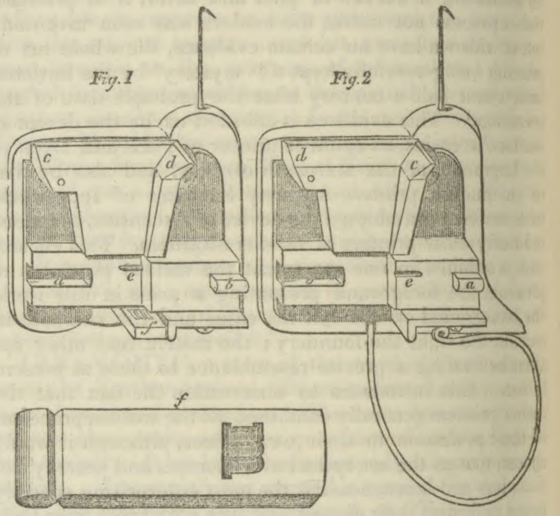
Nonpareil (Fr. and Ger. *Nompareille*), used for the same purposes as Minion. 143 ms = 1 foot: half Pica.

Ruby (no body to correspond in France or Germany), used for pocket dictionaries, prayer-books, &c.; but it is too small for any but the strongest sight. 163 ms = 1 foot: half Small Pica.

Pearl (Fr. *Parisienne;* Ger. *Perl*), used for the same purposes. 178 ms = 1 foot: half Long Primer.

Diamond (Fr. and Ger. *Diamond*) is the smallest body cut; it is distressingly small, and is used mostly for notes to works in Nonpareil and the descending bodies. The French have succeeded in cutting the face so small as to be illegible, and an annual lately sold in London in this letter is accompanied with a magnifying glass. 205 ms = 1 foot: half Bourgeois.

The principal apparatus in the casting of type are the punch, the matrix, and the mould. The punch (or puncheon) is a piece of steel bearing upon one end a single letter, which is formed by hammering, filing, and other processes, and differs in no other respect from ordinary punches than the unusual care and accuracy with which it is worked. It must be remembered, that as each letter is but one of a large number with which it is to harmonize, the height must be obtained with the greatest precision, the breadth both of the heavy and the fine strokes must be carefully proportioned, the turns graceful. This general harmony is not very difficult to attain in the coarser fancy type, there being in this, as in other arts, little merit in imitating the vulgar or the grotesque; but the elegant and symmetrical face of book type is as difficult to attain as the exquisite grace of the higher productions of the arts; and yet, to such perfection have modern artists attained, that the practised eye has little difficulty in assigning an individual letter to its proper fount, and even, if the printer has turned his attention to the particulars of his art, to the foundery and the artist, the punch-cutter of a foundery of character having a professional reputation, like a painter or engraver. Mr Moxon, a mechanician of great ingenuity, in his Mechanical Exercises, has the credit of first assigning rules for the shaping of letters, laying down geometrical rules for the angles of inclination, the curves, and for adjusting the base from which the shoulders of the letter should rise to obtain the greatest strength. From this the modern artists have varied, obtaining great sharpness of appearance combined with strength and durability. Although beyond a doubt Mr Moxon's formulæ have been of great advantage to subsequent punch-cutters, he was by no means a successful artist himself; his type, cut upon the most philosophical principles, being uglier than that of his contemporaries. The matrix is a small piece of copper into which the punch is struck. Much care is also requisite in doing this, although, provided it be struck sufficiently deep, the surface of the copper may be filed down so as to leave the impress of the exact depth. It has been explained in the article PRINTING, that to obtain equality of impression the face of the composed type must be in an exact plane, from which it will be easily understood that the just depth of the impression in the matrix is a matter of much importance. The copper must now be carefully dressed at the ends and sides, in order that when adjusted in the mould, the character, when cast, may be so placed upon its body that it shall stand exactly even with its brother characters: the nicety required in this is surprising.



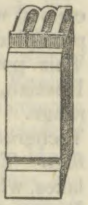
The mould is a very simple but very ingenious apparatus, consisting of two parts, so contrived that, being properly placed together (viz. *a* 2 in *a* 1, *b* 1 in *b* 2, *c* 2 on *c* 1, and *d* 1 on *d* 2), they form, in the centre *e*, a space, which is geometrically described as a parallelopiped, being, in fact, the mould in which the type is formed; the matrix *f* is placed at the bottom; the metal is poured in at the orifice formed by the closing of the upper parts. It will be seen that the two parts which form the mould slide upon each other, and that the extent to which they close is regulated by the width of the matrix; and that therefore all types of one fount, whether the broad 4-m quadrat or the narrow i or l, may be cast in the same mould. The spring at the bottom of figure 2 retains the matrix in its place, and without removing it the new letter cannot be disengaged; the hooks at the top are used to remove the letter from the mould. *f* is an enlarged drawing of the matrix.

The caster, with this apparatus, stations himself by the side of a furnace containing the melting pot and the fluid metal, of which he takes a portion with a very small ladle, and having poured in a sufficient quantity, jerks the mould into the air with his left hand (a very singular movement), which has the effect of expelling the air and forcing the metal into the finest strokes of the matrix. He then with one finger releases the spring, separates the mould, and hooks out the letter with one of the pieces of bent wire represented at the top of the mould; and so proceeds with considerable rapidity, casting about 500 letters in the hour, of ordinary sized type, although the smaller and the larger rant

re.

sizes require much more time, the first on account of the care requisite, and the latter to allow of the setting of the metal.

The types are now removed from the caster's table by a boy, who strikes off the knob at the bottom, caused by the superfluous metal at the orifice of the mould. A workman next rubs the sides of each letter upon a slab of very gritty stone (his fingers being guarded by a piece of leather), which removes any small knobs or globules attached to the sides or edges. This is done with great rapidity, from 1500 to 2000 letters being rubbed in an hour. The etters are then set up in a long stick, and again dressed, and the bottom grooved, by which exact height is insured; and the fount being then proportioned, is tied up, and is ready for the printer.

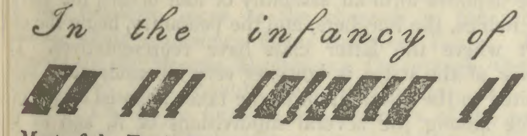


The matrix for very large type is differently prepared, he nicety of the punch-cutter's art not being required. The letter having been accurately shaped out by rule and ompass upon a piece of copper or brass, the part so marked out is cut away, care being taken to cut the back somewhat wider than the front, the sloping edge forming the houlder of the future type. The piece of brass now very much resembles the plates used for stencilling the large eadings of legal forms: it is next riveted upon a smooth urface of brass, which forms the face of the letter.

There is a peculiarity in script type which is deserving f mention. Script being an imitation of hand-writing, is necessary that the fine strokes at the beginning and nd of each letter should be in close contact with those of he preceding and succeeding letters. This M. Didot endeavoured to achieve by a very curious shape in the type, y which each should so lock in with the other that the required contact should not fail; but he carried his invention beyond the power of practice, for having resolved the characters into their component parts, he cast a series of igns exactly resembling the "pothooks and hangers" of a choolboy's copy-book, so that not only was every word to e composed, but every letter:

The English founders soon improved upon this idea, casting each letter complete. This however requires several etters to be cast in several forms, the initial, medial, and nal letters not being always quite alike. The following will give an idea of how script is cast and composed:

In the infancy of the art of Printing.



Most of the English type-founders, aware of the practical efects of this method, have, by a careful adjustment of the ne strokes at the beginning and end of each letter, cut ounts upon the ordinary square body, which answer every urpose. From the nature of the metal, however, and its ability to wear and become battered, script is an expenive fount.

(B. D.)

TYPOGRAPHY, the art of printing. See PRINTING.

TYRANT, among the ancients, denoted simply a king r monarch; but the ill use which several persons invested ith that character made of it, has altered the import of he word; and tyrant now conveys the idea of an unjust r cruel prince, who rules in a more despotic manner than he laws allow.

TYRE or SOUR, a seaport of Syria, anciently a city of xtensive commerce and great riches, but which has now allen into a state of insignificance and poverty. It was formerly called the Queen of the Sea, and ancient writers dilate with wonder on its magnificence and extent. The more ancient city of Tyre was founded by a colony of the Sidonians, on the shore of the continent: it was taken and destroyed by the king of Babylon, when a new city was built on an island about one third of a mile from the shore. Concerning continental Tyre we have no information except that which is contained in the Bible; from which we learn that it was a large, wealthy, and splendid city. Its existence is acknowledged by the Greek writers, but all trace of its history was lost, as it was destroyed before their time. It was never rebuilt, and not the least trace of it remains, nor could its site be determined. It was not known to have been built on the coast, opposite to the island. When Babylon was conquered by the Persians, the Tyrians were restored to comparative independence; and it was then that Tyre was rebuilt on the island, and attained greater splendour than before; and such was the power of this insular city, from the resources supplied by commerce, from its strength, and the advantages of its position, that it arrested the progress of Alexander's conquests longer than any place under the Persian dominions. That celebrated conqueror spent eight months before Tyre, and only succeeded at last by constructing an embankment or causeway between the mainland and the island, giving his troops and engines free access to the latter. The Tyrians however made such a valiant defence, and occasioned so great a loss to the conqueror, that he vented his rage on the conquered city, ordering 2000 of the inhabitants to be nailed to crosses, and 30,000 to be sold for slaves. In the storm of the city 8000 had been previously slain. He set fire to the town itself; yet it quickly recovered from the devastation of war, and, only nineteen years after, sustained a seige of fifteen months from the fleets and armies of Antigonus, when it was again taken. After this second capture, it was subjected, with all the surrounding country, to frequent changes of masters, from the continual contests which took place among Alexander's successors, the kings of Egypt and Syria, until it was finally absorbed, with all the rest of the world, in the growing empire of Rome. But by this time it had greatly declined in importance. The rise of Alexandria in Egypt was perhaps more injurious to the prosperity of Tyre than its capture by Alexander, as it gradually rose to be a great emporium of traffic, which it thus diverted from Tyre, and dried up the source from which its prosperity had flowed for about a thousand years. Through the skill and industry of its inhabitants, it still remained a considerable town, so long as the Roman dominion continued. Tyre declined with the rest of the Roman empire, under the devastations of barbarian conquest. It was subdued with the rest of Syria by the Arabs; in 1124 it was taken from them by the crusaders; Saladin made an ineffectual attempt to recover it in 1187; and it was finally taken in 1291, by Khalit, the sultan of Egypt, who razed it to the ground, that it might never again afford a stronghold to the Christians. It was taken by the Turks in 1516, when it was finally ruined; and it now presents to the traveller the aspect of a miserable and ruined village. It has been visited by many modern travellers, who all concur in giving the same account of this desolate place. It is called by Sandys a "heape of ruines." Volney describes it as a miserable village of fishermen, containing only fifty or sixty poor families, living but indifferently on the produce of their grounds and of a trifling fishery. The houses are wretched huts, ready to crumble into pieces. And thus we see the fulfilment of the prophecy, that Tyre should "be a place for the spreading of nets in the midst of the sea;" conveying a lively image of desolation, a convenient place for the drying of nets being generally a naked rock or beach. According to the most recent accounts, Tyre was beginning somewhat

Tyre.

to revive, a number of peasantry having come down from the neighbouring mountains to carry on the trade for which its harbour affords an opportunity. It is said by Turner to contain 200 inhabited houses or huts, two thirds of which are occupied by the tribe called Mutualis, while the rest of the inhabitants are chiefly Greek Catholics. There are also twelve Maronite families. The chief staple is tobacco, which is exported to Cairo and Damietta. To the same places are also sent charcoal, a number of dried figs, and large faggots of wood. There are a large pottery and a fishery. The walls of the town, about a mile in circuit, very old, falling to pieces, and patched up, may still be traced. In many places they are mended with large columns of red and gray granite, with two or three old cannon mounted upon them. On the west they are almost overwhelmed by sand; but on the south and east sides they are thirty feet high. On the south-west and south-east corners are the remains of ancient niches. The only gate is one of wood, on the eastern side; while on the north, part of the wall is broken down in order to allow a passage. The harbour stretches fifty feet along the shore, and 150 along banks that run into the sea. Near the walls are the ruins of two square Arab towers, one thirty-five and the other forty feet high; supposed by Pococke to have served as reservoirs of water, to be distributed from the aqueduct over the city. Without the walls are the ruins of a very large church, built, in the Syrian style, of hewn stone; also some very perfect remains of several buildings to the north, which are supposed to have belonged to the archiepiscopal palace. Long. 35. 20. E. Lat. 33. 10. N. (F.)

TYRHOOT, a district of Hindustan, in the province of Bahar, principally situated between the 27th and 28th degrees of N. lat. On the north it is bounded by the districts of Mocwanpoor and Muchwany, which are subject to Nepaul; on the south it has Hajypoor and Boghpoor; to the east, the Bengal district of Purneah; and on the west, Bettiah and Hajypoor. It is estimated to contain 5033 square miles. The surface, though not hilly, is more elevated, the soil drier, and the climate generally healthier, than those more to the south; although during summer it is liable to intense heats. It is well adapted for the breed of horses; and many of these valuable animals have accordingly been reared in this and the adjoining district of Hajypoor, to purchase which numerous horse-dealers from upper Hindustan have resorted to the fairs. The district is well cultivated, and produces grain, sugar, and indigo. Towards the northern frontier are extensive forests; but the timber cannot be floated down, owing to the want of water. The names of the rivers are, the Little Gunduck, the Bhagmati, and the Gogary. Along with the rest of the province, it devolved to the British, and was permanently attached in 1794, since which period it has improved greatly in population, cultivation, and commerce, large tracts of jungle having been brought into cultivation by the zemindars. In 1801, according to a census ordered by Marquis Wellesley, the inhabitants amounted to 2,000,000, in the proportion of one Mahommedan to four Hindus.

TYRNAU, a city of the Austrian kingdom of Hungary, the capital of a circle of the same name in the province of Hither Danube. It is the seat of the provincial courts of law, and contains nine churches, 660 houses, with 5700 inhabitants, chiefly employed in making linen and woollen cloths. It is a place of very active commerce. Long. 17. 29. 42. E. Lat. 48. 22. 53. N.

TYROL or TIROL, a province of Austria, one of those most early acquired by the imperial family. It takes its name from an ancient castle on a mountain, near the river Meran, which came under the house of Austria through a female, Margaretta Maultasche, in the year 1363. It extends in north latitude from 45° 39′ 30″ to 47° 41′ 15″, and in east longitude from 9° 28′ 5″ to 12° 32′ 23″, and contains 11,180 square miles. The province is divided into seven circles, comprehending twenty-two cities, thirty-six market-towns, and 3150 villages. The inhabitants were, in 1817, 717,524; but by the census of 1832, they appear to have increased to 805,750. They all adhere to the Roman Catholic Church, there being no Protestants or Greeks, and only eight or ten Jewish families. The whole of the province is a continuation of the Alps, and the face of the country resembles Switzerland, with some lofty mountains capped with snow, having between them similar profound precipices, thundering cascades, and extensive glaciers. This portion of the Alps, known to the ancients as the Rhetian, contains some of the loftiest mountains of the range. The Orteler exceeds 14,000 feet in height, the Tschernowand is 11,600, and a great number above 8000 feet. This mountainous district abounds in most beautiful lakes, which are the sources of several rivers, the Etsch, the Brenta, the Drave, and the Gail, which run to the Adriatic; and of the Isar, the Lech, the Iller, and the Inn, which finally empty themselves into the Danube. The air is pure and cold, but the too frequent sirocco in the summer has often a most injurious effect on the health of the inhabitants.

From the nature of the country, the far greater part is inaccessible to agriculture. The woods are estimated to be about three times the extent of the pasture and arable land together; and of about 1,800,000 acres, not more than 170,000 are capable of being ploughed; whilst the pasture land, in which are included those parts of the Alps which afford in the summer only food for cattle, are estimated at 600,000 acres. In the valleys, and lower sides of the hills, about 20,000 acres are appropriated to vineyards and gardens. The district is every year deficient in corn, and receives supplies from its neighbourhood, although the cultivation of potatoes, of maize, and of buckwheat, is extensive, and supplies substitutes for wheat, rye, and barley. The chief agricultural products which exceed the demands of the population are butter, hemp, tobacco, flax, and on the southern border, towards Italy, some silk.

The country is rich in minerals, but that branch of industry is languishingly pursued. The mines yield gold about 200 ounces, silver 16,000 ounces, and some iron, lead, calamine, and much rock-salt. Some iron and sheet wares are exported, as well as wine, tar, pitch, horses, cheese, and butter, chiefly to Italy. From the poverty of the country, the emigration is very great; and in every part of Europe the natives of it are to be seen, who, after successful wanderings, return to enjoy the proceeds of their industry and parsimony in their native land. The Tyrol has some privileges beyond the other portions of the Austrian states. The deputies form an assembly of four orders, the clergy, the nobles, the burghers, and the peasantry, being the only part where the latter class have representatives. The power of the states is however very inconsiderable, being limited to the distribution of the taxes imposed on the province among the several subdivisions of it, and to the privilege of petitioning and remonstrating.

TYRONE, an inland county of the province of Ulster, in Ireland, is bounded on the north by the counties of Donegal and Londonderry, on the east by Lough Neagh and the county of Armagh, on the south by the counties of Monaghan and Fermanagh, and on the west by those of Fermanagh and Donegal. It lies between 54° 20′ and 54° 59′ north latitude, and 6° 15′ and 7° 57′ west longitude; measuring forty-six miles in its greatest length from north to south, and sixty-three in its greatest breadth from east to west, and containing an area of 1269 square miles, or 806,296 acres, of which 714,500 are land, and of these, 544,000 acres are cultivated, and 170,000 bog or uncultivated mountain-land; and 31,796 are covered with water, part of which is a section of Lough Neagh. It is the ninth county as to its total extent of surface, and the eighth as to its quantity of cultivated land.

According to some authorities, the *Erdini*, and to others, he *Scoti.* were the earliest known inhabitants of this dis- rict. It was afterwards distinguished by the name of ineal-Evgain, or Tyr-Owen, and was the territory of the 'Neills, descendants of Neal of the Nine Hostages, king f Ireland, and virtually sovereigns of the greatest part of e north of Ireland for several centuries after the Eng- sh settlement under Henry II. In a writ of Henry III., e head of the sept is styled king of Kenilum or Tiroen. he chief seat of the family was at Dungannon, which, ough several times taken and sacked by the English rces in their attempts to reduce the country to obedience the royal authority, continued to be so until the close of e reign of Elizabeth, when it was burned by Hugh 'Neill, earl of Tyrone, to prevent its falling into the ands of Lord Mountjoy, who then commanded the queen's rces in Ireland. The insurrection of 1641 may be said have had its commencement in this county, by the cap- re of Charlemont Fort and Dungannon by Sir Phelim 'Neill; and in 1646 the parliamentary forces under Ge- ral Munroe received a signal defeat from Hugh Roe 'Neill at Benburb. During the greater part of the war tween King William and King James, this county was the possession of the forces of the latter, and suffered uch from the partisan warfare carried on there, chiefly by e townsmen of Enniskillen. It was also here that the lunteer convention of Dungannon assembled in 1782, d passed a series of resolutions expressive of their opi- on of the right of the Irish parliament to make laws in- pendently of that of Great Britain.

The surface is much varied, mostly hilly, with but little vel ground. In the north it rises into the mountain nge of Sperin, forming the boundary between the county d that of Londonderry. Its greatest elevations are Mul- ghcarne, 1890 feet; Straw Mountain, 2085; Muinard, 64; and Sawell, 2236. South of these is the lower dge of Slievekirk, Slievemore, and Munterlony, whose ghest point is 1432 feet. Mullaghcarne, north of Omagh, 1778 feet high; Slieve-Gallion, in the north-east, 1730; roagh, west, 1260; the mountains south of Clogher, hich form its boundary towards Monaghan, 1265 feet. wo mountains, detached from the main group, and si- ate on each side of the Mourne river, are distinguished y the popular names of Bessy Bell and Mary Gray. he former name has been supposed to owe its origin the pagan rites celebrated on its summit to the god el or Beal; for the latter no conjecture has been ha- rded. The eastern districts are chiefly flat, declining wards Lough Neagh. The valleys, several of which e very romantic, serve as the channels to the minor reams, whose confluence forms the river Foyle. The incipal are, the Mourne, Munterlony, Owenreagh, Owen- lloe, Derg, from Lough Derg in Donegal, and the ennet. The Foyle forms a small portion of the west- n boundary, the Blackwater a considerable part of the uthern, and the Ballinderry of the north-eastern. There e but few lakes, and those very small. Lough Fae, the foot of Slieve-Gallion, and Lough Creevy, are the rgest.

The substratum of the northern mountainous district is ica slate, interspersed with primary limestone in small de- ched portions. To the north-west is yellow sandstone ith conglomerate, which shows itself also in the central rt near Omagh, and again in the south-west, where it lunges into Fermanagh. A bed of granite, enclosed in ystalline greenstone trap, extends from Slieve Gallion early to Omagh. The formation across the county from ough Erne to Lough Neagh is the old red sandstone and ndstone conglomerate. In the south and south-east the rboniferous or mountain limestone appears; and near the orders of Lough Neagh are lyas, green sand, and chalk, with new red sandstone. In the sandstone formation in this part, fossil fish have been found, with the characteristic features of their various species strongly marked. Near Cookstown a great number of organic remains has been discovered. Coal is raised in large quantities in the eastern part, between Dungannon and Lough Neagh, in a district formed of a collection of low hills, not more than a hundred feet in perpendicular elevation, with steep sides and flattened summits. There are two principal fields; Coal Island, measuring about eight miles by three, and comprehending an area of 1200 acres; and Annahone, about a mile each way, and containing 500 acres. The coal, which is of the bituminous or blazing kind, like that of the west of Scotland, burning rapidly, and with a bright abundant flame, rests upon beds of fire-clay, sandstone, or blue clunch. The shale has impressions of vegetable substances, among which are reeds of very large dimensions. The quantity of coal raised is abundant in proportion to the extent of the field; but it is difficult to be worked, from the greatness of the angle formed by the layers of coal in many places, which increases the difficulty of drainage, and also from the soft nature of the bottom or flooring, which requires many precautions to prevent the passages from closing. Indications of coal have been perceived at Drunquin, to the north-west of Omagh, but no practical advantage has yet been taken of the discovery. Iron ore and potters clay are found in the coal districts. A range of escars extends across the southern part of the county, from near Dungannon to Five-mile-town; and the ridges are in some places as regularly arranged as if formed by the hand of man. There are many small bogs dispersed through the county.

The soil in the parts adjacent to Lough Neagh is alluvial, of considerable depth, and based upon limestone. The low lands along the Blackwater are extremely fertile, well timbered, and afford many prospects of great beauty. The valley of the Foyle, which belongs to this county, is also very fertile. The mountainous tracts to the north have a shallow soil, resting either on a tenacious clay, or on bog, which impedes the passage of the water, and renders the land moist, cold, and unproductive. Much of the central parts present tracts of unprofitable bog and heath. The southern districts are well wooded.

The progress of population during the last hundred years is as follows, according to the authorities stated:

Year.	Authority.	Number.
1760	De Burgo	76,278
1792	Beaufort	159,000
1812	Parliamentary census	250,746
1821	Ditto	261,865
1831	Ditto	302,943

The proportion of population to the entire surface of the county is, according to the latest of these statements, as 1 to 2·12, and to the entire of the cultivated land as 1 to 1·83. There is therefore one individual to somewhat more than every two acres of land in general, and to every $1\frac{2}{3}$ths of an acre of productive land. According to the returns of the Commissioners of Public Instruction in 1834, which, being taken by dioceses instead of counties, afford but an approximation to strict accuracy, the total population was 312,500, of which 69,320 were members of the established church, 69,620 Protestant Dissenters, and the remaining 173,560 Roman Catholics. The proportions of the different persuasions, the total population being taken as unity, are therefore 0·222, 0·223, and 0·555 nearly; whence it appears that the Roman Catholic population is more than equal to that of the Protestant, which also is almost equally divided between the established church and the Dissenters. The number of children receiving instruction in public schools, according to the population returns of 1821, and the Reports of the Commissioners of National Education in 1824–6 and in 1837, was as follows:

Year.	Males.	Females.	Sex not ascertained.	Total.
1821	8,484	4,078	—	12,562
1824–6	10,783	7,598	447	18,828
1837	4.383	2,581	—	6,964

Of the numbers stated in the return of 1824–6, there were, of the established church, 4824; Protestant Dissenters, 6404; Roman Catholics, 7480; besides 120 whose religious persuasion was not ascertained. And according to the same return, the number of schools was 435, of which eighty-nine, with 4861 pupils, were supported by grants of public money; eighty, with 5250 pupils, by private subscriptions; and the remaining 226, with 8717 pupils, wholly by the pupils' fees.

After the flight and attainder of the earl of Tyrone in 1607, the county was parcelled out by King James among English and Scotish settlers, or, as they were then styled, "planters," among whom the native Irish were distributed as tenants, except the swordsmen, who were dispersed throughout the waste districts of Munster and Connaught. Before that period, it was divided into two districts, called North and South Tyrone; but the northern part was about that time transferred to Londonderry, and the remainder divided into the five precincts of Clogher, Dungannon, Mountjoy, Omy, and Strabane. It now consists of the four baronies of Clogher, Dungannon, Omagh, and Strabane, which are subdivided into thirty-five parishes, of which twenty are in the diocese of Armagh, eleven in that of Derry, and four in Clogher; the cathedral and bishop's seat of the last named being in the county. Tyrone was represented in the Irish parliament by ten members, two for the county, and two for each of the boroughs of Augher, Clogher, Dungannon, and Strabane. By the act of union the number has been reduced to three, two for the county and one for the borough of Dungannon. The numbers of electors at different periods were as follows:

Year.	L.50.	L.20.	L.10.	Total.
1831	265	316	701	1282
1832	166	240	745	1151

	Total.		Total.		Total.
1833	1151	1836	1250	1838	1250
1834	1320	1837	1250	1839	3430
1835	2057				

The local government is vested in a lord lieutenant, twenty-two deputy lieutenants, and eighty-two other magistrates, besides a stipendiary appointed and paid by the crown, under whom there is a constabulary force of one county inspector, five sub-inspectors, six head constables, and 150 constables and sub-constables. The assizes are held at Omagh, where also are the county court-house and prison. There are bridewells at Clogher, Dungannon, and Strabane. General sessions of the peace are held at Strabane, Omagh, Dungannon, and Clogher; and there are eighteen stations for holding petty sessions. The number of committals for 1839 was 558, disposed of as follows: Discharged in consequence of want of prosecution, sixty; no bill being found, 100; acquitted by jury, 151; bailed and not tried, twenty; total, 331; convicted, 227, of whom there were discharged on securities, twenty-nine; fined, thirty; imprisoned for six months or under, 127; for one year, ten; for two years, three; transported for periods under seven years, ten; for seven years, fourteen; for fourteen years, four; for life, none; sentenced to death, none; to which general total are to be added seventy-three cases of summary convictions at petty sessions, and 190 for drunkenness. The public establishments for medical purposes are in different places. The county infirmary is at Omagh, the fever hospital at Strabane, and the accommodation for lunatics in the district-asylum at Londonderry. There are twenty dispensaries distributed through the county. Workhouses for unions under the new poor-law are in course of erection at Castlederg, Cookstown, Dungannon, Gortin, Omagh, and Strabane.

The modes of agriculture differ according to the character of the soil. In the alluvial lands in the east, tillage is pursued universally, and according to the most approved systems, both as to the treatment of the land and the construction of the implements. It is also extending into the mountainous district, wherever the nature of the soil or the declivity of the land admits of it. The spade, as an instrument of general husbandry, is less used every year, and the plough is substituted for it. Farms are generally small, not often extending beyond fifty acres. The land is much subdivided, except in the mountain districts, where farms are often held by a number of tenants, each of whom tills a quantity of the land proportionate to the amount of his rent, and enjoys the benefit of the remainder as pasture-land for his cattle, in common with the rest of the holders. In the more highly cultivated parts the fences are of white thorn; in the hilly country either of stone carelessly piled together, or, where stone is scarce, of sods topped with furze, here called whins. Land is now seldom allowed to lie fallow, as formerly, but is kept in a productive state by a judicious rotation of crops. Though it is not a pasturage country, and possesses but few extensive dairies, much butter is made, chiefly for the Scotish market. Cheese is also made in small quantities. The native cows are small, but good milkers. Great numbers of young cattle are fed on the mountains, and after a short time driven down to the lowlands for sale, where they are slaughtered, and sold under the name of horse-beef, because carried to the markets on horseback. The horses are hardy and excellent for field purposes, but are ill shaped. The breed of sheep is little attended to, whether for wool or carcass; nor are swine reared in the numbers usual in most other parts of Ireland, the vicinity of Strabane being the only part in which they form an important part of the farming stock.

The linen manufacture was long the staple trade; and though it lately declined here, as in other parts, for some years, yet it was never wholly relinquished: it is reviving to such a degree that it may now be considered to be in a flourishing and improving state. Bleach-greens were very numerous, but most of them have been applied to other uses, the linens wrought in the country being sold in a green state in all the principal towns. Wool is manufactured for domestic use into coarse cloths, blankets, and druggets; which last are still worn by the women, though their use is much diminished by the demand for cheap cottons. The favourite colour for broad cloths is a light blue. In spinning the wool, the oleaginous juice of the fern-root pounded is used instead of butter. Agricultural implements of every kind are manufactured at Coal Island; as are fire-bricks, considered to be equal to those of Stourbridge clay, and also crucibles. There are potteries in several places. Flour, tobacco, soap, and candles are manufactured to a considerable extent. There are several tanneries, distilleries, and breweries. The northern mail-road to Londonderry, through Strabane, traverses the county. The Ulster Canal passes along the southern border from Lough Neagh to Caledon, near which it enters Monaghan in its progress towards Lough Erne. The Foyle is navigable for small craft to St Johnstown, a village on the confines of the county, but on the Donegal bank of the river, and thence by an artificial cut to Strabane. The Blackwater is navigable for boats to Moy, and communicates with the collieries by a short canal. There is also a communication between the river and the collieries ne.

y a railroad. The line of railroad proposed by the com-
nissioners of railways to proceed from Armagh to Cole-
aine is intended to pass through Tyrone, near the western
oast of Lough Neagh, by Coal Island and Coagh. There
re nine banking establishments; three of which are
ranches of the Belfast, three of the Provincial, and three
f the Agricultural and Commercial Banks. There are also
ght registered loan-societies.

As every settler placed here by James I. was bound by
ıe conditions of his grant, if he held upwards of 1000 acres,
erect a castle with a bawn or fortified enclosure, numer-
ıs large buildings were raised, of a mixed character be-
veen the feudal fortress and the modern mansion, several
which are still the residences of the representatives or
ıccessors of the original grantees. Besides these there are
any elegant modern mansions and villas of the landed
entry. The houses of the more substantial farmers are of
one, generally well built and slated; the habitations of the
asantry very poor, owing partly to the want of timber,
ırtly to the poverty of the inmates. Turf is the general
el, except in the immediate vicinity of the collieries. The
od of the poorer classes is potatoes and oatmeal, with milk
ıd salt fish occasionally; flesh-meat is used only on festal
casions. In their dress, customs, and dispositions, they
ry little from those of similar station throughout the pro-
nce. Irish is scarcely spoken except in the retired moun-
in-districts.

A singular mode of medical treatment is practised in
me parts. A kind of rude cell is scooped out of the side
a hill or bank, and closed in the front with wicker-work
clay, leaving only a small opening for the entrance.
he interior being heated with charred turf, the patient is
id down in it, and the door being closed up so as to pre-
nt the admission of air, he is suffered to remain there un-
the action of the heat is supposed to have produced the
sired effect. This system is used in all complaints, but
iefly in rheumatic affections, which are very prevalent.
he poorer classes are much addicted to superstitious prac-
ces: they stand in great awe of fairies, or, as they call
em, "the wee people;" and still adhere to the custom of
iving their cattle round fires lighted at midsummer. An
tique bell, found among the ruins of a church, and
own by the name of the Clogh of Termon, is used as a
st to swear upon; and the donach, a box or casket contain-
g some relics, is employed for the same purpose.

There are many remains of raths and Danish forts, several
a state of good preservation; but their number is yearly di-
nishing, by their being dug up and carried away for farm-
g uses. Several fine monuments described as Druidical
to be seen. A very large cromlech rests on a hill near
ewtown-Stewart; another is near Coagh. Some remains
a round tower were visible at Errigal-keroge in the be-
nning of the present century, but no trace of it now ex-
s. Near Dungannon is an ancient relic, consisting of
o circles marked by upright stones, and connected to-
ther in the shape of the figure 8. Several brazen trum-
ts of singular construction were discovered about a
ntury ago near the same town. The remains of monas-
buildings and of ancient castles are numerous. Among
e most remarkable of the latter is that at Benburb, near
ich was one of the ancient residences of the O'Neills.

The population is chiefly rural. The largest town does not
ntain 6000 inhabitants, and there are but nine containing
population which exceeds 1000. The county town is
magh, nearly in its centre, on the Drumragh water or
roule, a branch of the Foyle. This town was twice de-
oyed by fire; the first time in 1689, by the garrison
ıced in it by King James, in order to render it useless
the enemy when they evacuated it; afterwards in 1743,
an accidental fire, which left but two houses standing.
ke most other places that have suffered by such a calamity, it rose much improved from its ashes, and is now remarkable for its general neatness, and the elegance of some of its buildings, particularly the court-house. The other public buildings are, the parish-church, with a lofty tower and spire, the Roman Catholic chapel, four dissenting chapels, the county-prison and infirmary, and a barrack. Omagh has some trade, and is one of the markets for brown linens. The population is 2211. Strabane, on the Mourne, near its confluence with the Finn, is the largest and most improving town in the county. Its situation is very picturesque; the natural beauties of its site being heightened by the numerous orchards and fruit-gardens in which it is embosomed. Its public buildings are, the parochial church, a Roman Catholic chapel, and four dissenting places of worship. It is a chartered borough, but the corporation is little regarded since it lost by the union its right of representation. Its only corporate property are the town tolls and customs. It carries on a brisk trade in grain and provisions, which is greatly promoted by a canal, three miles long, to Leck, on the Foyle, and navigable for barges of forty tons. The linen manufacture, after having been carried on here to a large extent, gave way to that of cotton, which has also declined.* The present thriving state of the place is owing to its general trade, and its position as a mart for receiving the agricultural produce of the interior and transmitting it to Londonderry: it also enjoys the advantage of a profitable fishery. The population is 5457. Dungannon, three miles west of the south-west extremity of Lough Neagh, was the principal residence of O'Neill, the head of the family, who here erected a large castle, which he afterwards burned, together with the town, when driven from it by Lord Mountjoy. The castle was rebuilt after the restoration, and the town much improved. Its public buildings are, the parish church, a Roman Catholic chapel, several dissenting places of worship, and one of the royal schools endowed by James I. The linen manufacture is still carried on with great spirit; and there are several bleach-greens in the neighbourhood. It has also manufactories of earthenware, fire-bricks, iron, and flour. It returns a member to the imperial parliament, for which purpose a new and more limited boundary has been laid down, comprehending but 224 acres out of 836, which is its extent for other municipal purposes. The population is 3515. Cookstown, on the road from Dungannon to Coleraine, has also a respectable share of the linen manufacture, chiefly for the supply of the English market. Its population is 2883. The other towns whose population exceeds 1000 souls each are, Auchnacloy, 1742; Newtown-Stewart, 1737; Fintona, 1714; Caledon, 1079; and Stewartstown, 1010. Clogher, where stood the cathedral of the diocese of the same name, a building of small dimensions and few architectural pretensions, though dignified with the title of city, from the circumstance of its being the seat of a bishop, is but a village, with a population of 523 inhabitants, who chiefly derive their subsistence from the expenditure of the family and dependents of the bishop, whose palace and demesne are in its vicinity. (C. P.)

Tyrtæus.

TYRTÆUS, a renowned poet, was an Athenian by birth, and flourished about 682 years before the commencement of the Christian era. He followed the occupation of a schoolmaster, was lame in one foot, and was considered as scarcely sound in mind. By the foolish, genius is sometimes mistaken for fatuity. The causes which led to his being placed in a more conspicuous situation were very peculiar. During their second war with the Messenians, the Lacedæmonians having consulted the oracle of Delphi, were directed to request the services of an Athenian general. The Athenians were unwilling to disregard the injunctions of the oracle, but they were also unwilling to assist a rival state in extending its dangerous power in the Peloponnesus; and with the view of at once complying with the form, and evading the spirit of the response, they sent the lame and eccentric poet to Sparta. By the force of his genius, he speedily effaced the first impressions occasioned by the meanness of his personal appearance; but his victories were achieved by the lyre and not by the sword. He composed various poems in praise of valour and patriotism, and breathed a new spirit into the rude soldiers of Sparta. When they had been thrice repulsed, and their leaders were on the point of ordering a retreat, Tyrtæus, by loudly reciting his noble verses, roused the drooping courage of the army to such a height, that every warrior prepared to conquer or die. In the anticipation that they might all perish on that bloody field, they each fastened on the right arm a ticket, containing his own name and that of his father, lest, in the general mass of carnage, it might be impossible to recognise their mangled bodies. The Messenians fought with great valour and determination, but the Lacedæmonians at length obtained the victory. When civil discords afterwards arose at Sparta, they were dispelled by the potent song of Tyrtæus. As a reward of his eminent services, he was admitted to the rights and privileges of a citizen. According to the statement of Lycurgus, they passed a law, enjoining as a preparation for battle, that the soldiers were to assemble at the king's tent, in order to listen to the recitation of this poet's verses, so well calculated to inspire them with a contempt of danger and death.[1] Of the literary history of Greece, very few portions are so singular as that which we have now detailed; nor must it be forgotten that the people among whom poetry effected such wonders, were never distinguished by the cultivation of literature.

Of the fragments of Tyrtæus, the earliest edition is supposed to be that which M. Aurogallus published along with the Hymns of Callimachus, Basil. 1532, 4to. They were afterwards inserted in various collections, those of Turnebus, Winterton, Brunck, Gaisford, and others. A separate edition was published by Dr Moor, Glasg. 1759, 4to. Two editions, much more elaborate, were published by Klotz, Bremæ, 1764, 8vo, Altemb. 1767, 8vo. This second impression contains various additions and improvements. But the most valuable edition that has yet appeared is included in a volume bearing the title of "Jo. Valentini Franckii, Philos. D. Callinus; sive, Quæstionis de Origine Carminis Elegiaci Tractatio critica. Accedunt Tyrtæi Reliquiæ, cum procemio et critica annotatione." Altonæ et Lipsiæ, 1816, 8vo. The fragments of Tyrtæus, almost entirely in elegiac verse, are eleven in number, but only two of them extend to any considerable length. One of them consists of a single verse. The fragment beginning Μέχρις τεῦ κατάκεισθε; which is frequently printed among those of Tyrtæus, is by the best critics assigned to Callinus.

TYRWHITT, Thomas, a distinguished scholar, was born in London on the 29th of March 1730. His father Dr Robert Tyrwhitt, descended from an ancient baronet's family in Lincolnshire, was at that time rector of St James's, Westminster; but this benefice he resigned in 1732, on being appointed a canon residentiary of St Paul's. With this preferment, he held the prebend of Kentishtown, and the archdeaconry of London. In 1740 he became a canon of Windsor; and, if his life had been prolonged, he might perhaps have attained to a higher station in the church; but he died on the 15th of June 1742, at the early age of forty-four. By his wife, the eldest daughter of Bishop Gibson, he left a numerous family, with only a moderate provision. His eldest son Thomas was sent to a school at Kensington, after he had completed the sixth year of his age. In January 1741 he was removed to Eton, where he first displayed that ardent love of literature for which he continued through life to be eminently distinguished. It was said of Tyrwhitt that he never was a boy, his calm and contemplative disposition always leading him to manly and scholar-like pursuits. After residing at Eton for six years, he was in 1747 entered of Queen's College, Oxford. He took the degree of A. B. in 1750; and having been elected to a fellowship of Merton in August 1755, he took that of A. M. in the ensuing year.

He had previously hired chambers in the Temple, and applied himself to the study of the law; but in December 1756 he was appointed under secretary at war, the principal secretary being his friend and patron Lord Barrington. In August 1762 he obtained the more lucrative office of clerk of the House of Commons, and he then resigned his fellowship. "If the fatigues of the clerkship," says one biographer, "had not proved too much for his constitution, it is thought that some of the higher offices of the state were within his reach." He resigned his office in January 1768, and passed the remainder of his life in learned retirement. In 1784 he was elected a curator of the British Museum, and was zealous in discharging the duties connected with this honourable appointment. To the Museum he bequeathed a portion of his valuable library, comprehending such books as it did not already possess. His constitution had never been robust; and having been attacked by two violent disorders, he expired on the 15th of August 1786, in the fifty-seventh year of his age. He died at his house in Welbeck-street, Cavendish-square, and was interred, as his father had also been, in St George's Chapel, Windsor. He left behind him the character of a learned and amiable man. "In private life," we are informed, "he was a man of great liberality, of which some striking instances are given. In one year it is said he gave away L.2000, and for such generous exertions he had the ability as well as the inclination, for he had no luxuries, no follies, and no vices to maintain. Of such a man it is unnecessary to add, that he died lamented by all who knew the worth of his friendship, or enjoyed the honour of his acquaintance."

Tyrwhitt was a man of solid as well as extensive erudition; well acquainted with the modern, and eminently skilled in the ancient languages. He was an able Grecian; and his name is held in much respect by the scholars of the continent. He distinguished himself by his sound judgment and critical sagacity; nor was he less distinguished by the modesty and candour which he carried into all his inquiries. He bore no resemblance to those verbal critics who seem to have dipped their pens in gall whenever they enter upon the discussion of a controverted point, however minute.

His earliest publication was "An Epistle to Florio at Oxford." Lond. 1749, 4to. This was followed by "Translations in Verse." 1752, 4to. Here Pope's Messiah and Philips's Splendid Shilling appear in Latin, and the eighth Isthmian ode of Pindar in English. His next work, which is but of small extent, is entitled "Observations and Conjectures on some Passages of Shakspeare." Oxford, 1766, 8vo. On the same poet he afterwards communicated various annotations to Steevens and Reed, for their editions of 1778 and 1785. His edition of another English poet brought him a considerable increase of reputation: "The Canterbury Tales of Chaucer. To which are added, an essay on his language and versification; an introductory discourse; and notes." Lond. 1775-8, 5 vols. 8vo. Oxf. 1798, 2 vols. 4to. Lond. 1830, 5 vols. 8vo. He afterwards lent his aid to the publication of "Poems, supposed to have been written at Bristol, by Thomas Rowley and others, in the fifteenth century; the greatest part now first published from the most authentic copies, with an engraved specimen of one of the MSS. To which are added hitt.

---

[1] Oratores Attici, tom. iv. p. 451. edit. Dobson.

preface, an introductory account of the several pieces, and glossary." Lond. 1777, 8vo. This volume was twice reinted in 1778, with the addition of an appendix, tending prove that the poems were all written by Chatterton. yrwhitt's opinion, which is now sufficiently confirmed, was posed by several writers, one of whom was Mr Bryant, d another Dr Milles, dean of Exeter. The former pubhed an elaborate volume of nearly six hundred pages. e returned an able and temperate answer, under the title "A Vindication of the Appendix to the Poems called owley's, in reply to the Answers of the Dean of Exeter, cob Bryant, Esquire, and a third anonymous writer; with ne further Observations upon those Poems, and an Exanation of the Evidence which has been produced in suprt of their Authenticity." Lond. 1782, 8vo. The word *thenticity*, it may be remarked, is here improperly used itead of *genuineness*. On this controversy, several other tcts were produced. Tyrwhitt's opinion was adopted by arton, and was opposed by Mathias.

These were the principal works of literature which he pblished in English. He was however the editor of other t works which deserve to be mentioned. "Proceedings al Debates in the House of Commons in 1620 and 1621; frn the original MS. in the library of Queen's College, ford: with an appendix." Oxf. 1766, 2 vols. 8vo. "The nner of Holding Parliaments in England. By Henry ynge, Cler. Par. Corrected and enlarged from the author's ginal MS." Lond. 1768, 8vo. He likewise superinded the posthumous publication of his learned friend Musgrave: "Two Dissertations. I. On the Græcian thology. II. An Examination of Sir Isaac Newton's Objions to the Chronology of the Olympiads." Lond. 1782, 8. For this work a very liberal subscription had been raed, entirely by the exertions of Mr Tyrwhitt, who had pviously relinquished to the author's widow a bond for sevl hundred pounds, which he had lent to her husband.

is classical labours, though not very extensive, have seured him a high reputation as a scholar. In 1773 he plished from a Harleian manuscript "Fragmenta duo Ptarchi;" and after an interval of three years appeared h"Dissertatio de Babrio, Fabularum Æsopearum Scripte. Inseruntur Fabulæ quædam Æsopeæ nunquam antc editæ, ex cod. MS. Bodleiano. Accedunt Babrii Fgmenta." Lond. 1776, 8vo. Of Babrius, otherwise ced Babrias or Gabrias, the personal history is altogether olcure. Tyrwhitt supposes him to have flourished during th age of Augustus, or somewhat earlier. Avianus states th he compressed two volumes of fables into Greek iambi: "quas Græcis iambis Babrius repetens, in duo volua coartavit." Suidas informs us that he changed ten bks of Æsopean fables into choliambic verse. His scazons apar to have been afterwards reduced to prose; and Twhitt considers it probable that all the prose fables now being the name of Æsop have been fabricated from Babrs. "Mihi sane hæc cogitanti verisimile videtur, collecties omnes, quas hodie tenemus, fabularum Æsopearum alpere Babriano originem suam duxisse, differentias autem em scriptorum multitudini imputandas esse, qui diversis teporibus, et locis, et ingeniis, et studiis, metrorum elegissimorum partes varias, pro libitu suo quisque, in pram traducendas sumpserunt." In the Bodleian Library hefound a MS. which, being inaccurately described, had esped the notice of Dr Hudson, although he was keeper ofhat library when, in 1718, he published his edition of Æp. Various fragments of Babrius are yet to be found ineir original state; and the learning and sagacity of Btley, Tyrwhitt, and other critics, have frequently enabled thn to restore his verses from their transposed form. The mits of this dissertation are duly acknowledged by Knoch, th most recent editor of Babrius. A sequel to it was soon afrwards published. "De Lapidibus poema, Orpheo a quibusdam adscriptum, Gr. et Lat. ex editione J. M. Gesneri. Recensuit notasque adjecit Thomas Tyrwhitt. Simul prodit Auctarium Dissertationis de Babrio." Lond. 1781, 8vo. Both the dissertation and the *auctarium* were reprinted under the superintendence of Harles, Erlangæ, 1785, 8vo.

Tyrwhitt had contributed various notes on Euripides, which appeared in Musgrave's edition, published at Oxford in 1778 in 4 vols. 4to. He afterwards produced his "Conjecturæ in Strabonem." Lond. 1783, 8vo. Erlang. 1788, 8vo. The last work which he lived to publish was an edition of the oration of Isæus "De Meneclis Hereditate." Lond. 1785, 8vo. He had bestowed no small labour in the preparation of another work, which was conducted through the press by Dr Burgess, afterwards bishop of Salisbury: "Aristotelis de Poetica liber Græce et Latine. Lectionem constituit, versionem refinxit, animadversionibus illustravit Thomas Tyrwhitt." Oxonii, 1794, fol. 4to & 8vo. These animadversions, which may be regarded as his principal work, are very able and elaborate. Another posthumous publication appeared after a considerable interval: "Thomæ Tyrwhitti Conjecturæ in Æschylum, Euripidem, et Aristophanem. Accedunt Epistolæ diversorum ad Tyrwhittum." Oxon. 1822, 8vo.

(x.)

Tytler.

TYTLER, WILLIAM, one of the most strenuous defenders of the immaculate purity of Queen Mary, was born at Edinburgh on the 12th of October 1711. He was the son of Mr Alexander Tytler, a writer or attorney in Edinburgh, by Jane the daughter of Mr William Leslie, merchant in Aberdeen, and granddaughter of Sir Patrick Leslie of Iden, provost of that city. He received his education at the High School and the university of his native city, and distinguished himself by an early proficiency in those classical studies which, to the latest period of his life, were the occupation of his leisure hours, and a principal source of his mental enjoyments. At the age of thirty-one he was admitted into the society of writers to the signet, and till the time of his death he continued the practice of his profession with very good success, and with equal respect from his clients and the public. In September 1745, he married Anne Craig, daughter of Mr James Craig of Dalnair, writer to the signet, by whom he left two sons and a daughter. In 1759 he published his "Inquiry, Historical and Critical, into the Evidence against Mary Queen of Scots, and an Examination of the Histories of Dr Robertson and Mr Hume, with respect to that Evidence." Here he warmly espoused the cause of that unfortunate princess, and attacked with severity the conduct of her enemies. On this subject, most of his opinions have already become obsolete. On its first appearance, the book was much read in Britain, and was translated into French. He afterwards published the "Poetical Remains of James the First, King of Scotland." Edinb. 1783, 8vo. This volume includes a dissertation on the life and writings of the royal author, and a "Dissertation on the Scottish Music." He contributed several papers to the first volume of the Transactions of the Society of Antiquaries of Scotland. In the Lounger he wrote a single paper, No. 16. Mr Tytler died on the 12th of September 1792. In domestic life his character was particularly amiable; and he is said to have been one of the kindest of husbands, and most affectionate of fathers.

TYTLER, *Alexander Fraser*, the eldest son of William Tytler, noticed in the preceding article, was born at Edinburgh on the 15th of October 1747. In his eighth year, he was sent to the High School, where he became dux of the rector's class. In 1763, he was placed under the care of Mr Elphinston, who then kept an academy at Kensington. Here he enlarged his stock of classical knowledge, and cultivated his talent for Latin versification. One of his poems was communicated to Dr Jortin, an excellent judge, who encouraged the youthful writer by his commendation, and presented him with a copy of his own

Tytler.

Latin poems. After a residence of two years he quitted Kensington, and in 1765 entered the university of Edinburgh, where he had the advantage of prosecuting his studies under Dr Ferguson and Dr Blair. His range of enquiry was sufficiently ample, but his chief efforts were directed to literature and jurisprudence. He continued to increase his familiarity with the Greek and Latin writers, nor did he neglect the study of modern languages. Music and drawing were added to his other accomplishments. Natural history became, and long continued to be, one of his favourite recreations.

He was called to the bar in 1770; and in the spring of the ensuing year, he accompanied his relation Mr Kerr of Blackshiels on a tour to Paris, from which they returned by Flanders and Holland. At the age of twenty-four he published "Piscatory Eclogues, with other Poetical Miscellanies, by Phineas Fletcher: illustrated with notes, critical and explanatory." Edinb. 1771, 8vo. In 1776 he married Anne, the eldest daughter of William Fraser, Esq. of Balnain. When the Works of John Gregory, M.D. were published in 1778, he contributed the preliminary account of the author's life and writings. During the same year, he published a folio volume, supplementary to Lord Kames's Dictionary of Decisions. Although he never rose to high practice at the bar, he did not neglect the learning of his profession; but soon after this period he sought and obtained an academical office. In 1780 he was appointed conjunct professor with Mr Pringle, and in 1786 he became sole professor of civil history. From his first appointment till the year 1800, he devoted his attention almost exclusively to the duties of his professorship; and ten years of assiduous study were employed in the composition and improvement of the course of lectures which he annually read in the university. His lectures were considered as valuable, and they continued to attract a very respectable auditory. For the use of his students, he printed a "Plan and Outlines of a Course of Lectures on Universal History, Ancient and Modern." Edinb. 1782, 8vo. This compendium was afterwards enlarged, and published under the title of "Elements of General History, Ancient and Modern." Edinb. 1801, 2 vols. 8vo. In 1822 a supplementary volume was added by Dr Nares, professor of modern history at Oxford. Mr Tytler's next, and, according to our judgment, his best work, bears the title of an "Essay on the Principles of Translation." Lond. 1791, 8vo. The third edition, with large additions, appeared at Edinburgh in 1813. This essay, originally published without the author's name, experienced a very favourable reception, and still continues to be regarded as a judicious and learned work.

In 1790 he was appointed judge-advocate of Scotland. On the death of his father in 1792, he succeeded to the estate of Woodhouselee near Edinburgh; and on the death of his father-in-law, he had previously succeeded to that of Balnain in the county of Inverness. In 1795 he was seized with a dangerous fever, which was of long continuance, and was accompanied with delirium. When he was sufficiently recovered, he resumed his favourite pursuits, and occupied himself with preparing an edition of Dr Derham's Physico-Theology, including an account of the life and writings of the author, and a short dissertation on final causes, together with notes. This edition was printed in 1799. During the same year he wrote a pamphlet, which was published at Dublin under the title of "Ireland profiting by Example; or the Question considered, whether Scotland has gained or lost by the Union." Of this well-timed tract, three thousand copies were sold on the day of its publication. His next production was "An Essay on Military Law, and the Practice of Courts Martial." Edinb. 1800, 8vo. A second edition was printed at London in 1806. He contributed the critical remarks, inserted without his name in an edition of the Poems of Allan Ramsay. Lond. 1800, 2 vols. 8vo. The biographical account of the poet was contributed by a writer greatly inferior to Mr Tytler.

The literary, professional, and, we may add, political merits, of the learned professor, were too conspicuous to be overlooked. On the second of February 1802 he took his seat in the Court of Session, with the title of Lord Woodhouselee. To the duties of his new station he devoted himself with scrupulous assiduity; but the long vacations left him abundant leisure for his literary pursuits. He devised several projects which he did not live to execute. One of these was a life of George Buchanan; "in which," as we are informed, "he proposed to do ample justice to his genius as a poet, and his merits as a historian, but to examine, with firmness and accuracy, his conduct as a man and as a politician." It is easy to conjecture that Buchanan's politics could not be very highly approved by Lord Woodhouselee. He however found another subject for his biographical labours, and published a very copious work, under the title of "Memoirs of the Life and Writings of the Hon. Henry Home of Kames." Edinb. 1807, 2 vols. 4to. This work, which was reprinted in octavo, contains an ample store of historical and literary information, and in various respects is very creditable to the author. Like all other works, however, it is not without its defects. The author's manner of writing is too diffuse; his muster-roll of great men is much too great; and not a few subjects and characters seem to be viewed through the dim and narrow expanse of political prejudice. In this modern judge, the conduct of Sir George Mackenzie found a zealous defender. His lordship, we are inclined to think, was more laudably employed in preparing for the press "An Historical and Critical Essay on the Life and Character of Petrarch: with a Translation of a few of his Sonnets." Edinb. 1810, 8vo. The greater part of this work had appeared in two separate publications; the one a small pamphlet, printed with a similar title twenty-five years before; the other a dissertation or an historical hypothesis of the Abbé de Sade, printed in the fourth volume of the Transactions of the Royal Society of Edinburgh. In the year 1811, he was appointed a judge of the Court of Justiciary. This new preferment he did not long enjoy. For some time he laboured under a disease which he himself contemplated as fatal, but the termination of his earthly career was very sudden. He died at his house in Prince's-street, on the 5th of January 1813, in the sixty-sixth year of his age.[1]

Lord Woodhouselee appears to have been an amiable as well as an accomplished man. He was gentle and polished in his manners. At every period of his life, he was distinguished by his love of elegant literature. He had cultivated classical learning with perseverance and success; and even during his advanced years he continued to seek a change of tasteful recreation in the composition of Latin verses. Some specimens have been printed. In the Mirror and the Lounger he wrote various papers, and he was likewise a contributor to the Transactions of the Royal Society. He left a widow, with four sons and two daughters. The eldest son succeeded to the estate of Balnain, and the second to that of Woodhouselee. Another son, Alexander, published a work entitled "Considerations on the present Political State of India." Lond. 1815, 2 vols. 8vo. His youngest son is the author of the History of Scotland, and other performances well known to the public.

TZULIM, or Tchulimm, a river of Asiatic Russia, which runs through the province of Kolivan, and falls into the Yenisei. Its course is through a poor and desolate country, with scarcely a house or an inhabitant, but only tall pines rising like pyramids, and spreading their branches so wide as to render the woods almost impassable. The only inhabitants are Tartars, who are sunk in the lowest state of barbarism.

---

[1] Transactions of the Royal Society of Edinburgh, vol. viii. p. 515.

U.

U, or u, the twentieth letter and fifth vowel of our alphabet, is formed in the voice by a round configuation of the lips, and a greater extrusion of the under one han in forming the letter o. The sound is short in *curst*, *nust*, *tun*, *tub*; but is lengthened by a final *e*, as in *tune*, *ube*, &c. In some words it is rather acute than long; as *brute*, *flute*, *lute*, &c. It is mostly long in polysyllables; s in *union*, *curious*, &c.; but in some words it is obscure, s in *nature*, *venture*, &c.

UBEDA, a city of Spain, in the province of Andalusia, the division called the kingdom of Jaen. It is situated in fertile district, on a gentle elevation, but is well protected om the cold north winds by the loftier elevations of the ierra Nevada. The vegetable products are, corn, grapes, lives, and especially figs; but from the want of even assable roads, and of access to any of the great cities, ere is little inducement to cultivate beyond the demands the immediate vicinity. The breed of horses is highly lued, as the only article sold beyond the limits of the district. Being a frontier town between the Moors and the hristians so long as the former maintained themselves in ranada, it was the scene of numerous and sanguinary nflicts. Like the other cities in this part of Spain, it has, perhaps had, a very great number of churches, convents, d nunneries. The inhabitants are stated to be about ,000, a few of whom are occupied in making coarse oollen stuffs for domestic use. Ubeda is thirty miles from e city of Jaen, and fifty-four miles from Granada. Long. . 18. W. Lat. 38. 3. N.

UBIQUITARIANS, a word formed from *ubique*, everyhere, denotes a sect of Lutherans which arose and spread self in Germany, and whose distinguishing doctrine was, at the body of Jesus Christ is everywhere, or in every ace. Brentius, one of the earliest reformers, is said to ave first broached this error in 1560. Luther himself, in is controversy with Zuinglius, had used some unguarded xpressions, which seemed to imply a belief of the omnipreence of the body of Christ; but he afterwards became sensile that this opinion was attended with great difficulties, and articularly that it ought not to be made use of as a proof Christ's corporal presence in the eucharist. After the eath of Luther, this absurd hypothesis was exhibited in a ecious and plausible form by Brentius, Chemnitius, and ndreas, who maintained the communication of the proerties of Christ's divinity to his human nature. It is ineed obvious, that every Lutheran who believes the docine of consubstantiation, whatever he may pretend, must e an Ubiquitarian. See SUPPER OF THE LORD.

UBIQUITY, OMNIPRESENCE, an attribute of the Deity, hereby he is always intimately present to all things.

UBRIQUE, a city of Spain, of the province of Andaisia, in the western part of the government of Granada, etween the Sierra of the Alpuraxis and that of Antequera, a most picturesque country. It is nestled in the botom of a deep valley, hemmed in by singularly rugged ountains. The valley is pierced by two streams, which re conducted to the town, and form the river Majaceite, nd fertilize a belt of ground around the city, of most luxuriant egetation. The streets are wide, clean, and well paved, he houses lofty and good, but with scarcely any furniture. The population is estimated at 8000 souls. They have some anneries, and manufacture some hats and coarse cloth. In the neighbourhood are some mines of copper, which were formerly worked, but have for many years been abandoned.

UCKFIELD, a town in the hundred of Loxfield-Dorset and rape of Pevensey, in the county of Sussex. It is situated on the great road to Lewes and Eastbourne, forty-one miles from London. It is well built, clean, and flourishing, chiefly depending on the travelling through it. It is a part of the parish of Buxted. The population amounted in 1821 to 1099, and in 1831 to 1261.

UDINE, a city of Austrian Lombardy, the capital of the delegation of Friuli, in the government of Venice. It is surrounded with walls, and stands on the river Roja di Palma, in a hilly country, 350 feet above the level of the sea. It is a well-built city, and kept in good order, but, from the narrowness and crookedness of the streets, has a gloomy appearance. There is however a fine plaza or market-place, ornamented with a column and statue to commemorate the peace of Campoformio, which was signed in a village near this city in 1797. It is the seat of an archbishop, has a cathedral, twelve churches, and several oratories or chapels. The episcopal palace is a fine building, and so is the opera-house; and some others are worthy of notice, though almost hidden by the meaner buildings that surround them. There are public institutions for charitable and educational purposes, but they are for the most part on a contracted scale. The population in 1830 amounted to 17,560 persons, whose chief occupation arises from the breeding of silk-worms, and from the labour of winding and spinning. There are also some manufactures of linen goods, considerable tanneries, and a few paper-mills. The gloomy appearance of the city is somewhat relieved by several fine promenades in the contiguous suburbs. Long. 13. 8. 57. E. Lat. 46. 3. 14. N.

UDIPU, a town of the south of India, province of Canara, about three miles from the sea, on a small river. It contains 300 houses and three Hindu temples, the roofs of which are covered with copper. Long. 74. 48. E. Lat. 14. 10. N.

UFFCULME, or UFFCOLUMB, a market-town and parish in the hundred of Bampton and county of Devon, 160 miles from London. It has a good market on Wednesday, and some fairs. The trade in serges has become extinct. The population amounted in 1821 to 1979, and in 1831 to 2082.

UGLITSCH, a circle of the Russian government of Jaroslaw. It extends in north latitude from 57° 17′ to 58° 11′, and in east longitude from 38° 17′ to 39° 8′. It comprehends one city and 374 towns and villages, with 68,840 inhabitants. The land is of moderate fertility, watered by the Wolga, the Jugol, and the Uleima; and it yields tolerable crops of corn, while the meadows afford good pasture for horned cattle. The capital is the city of the same name, situate on the river Wolga. It contains twenty-five churches, 1100 houses, in narrow and crooked streets, and 7300 inhabitants, who are chiefly occupied in the manufacture of coarse paper, linen and woollen fabrics, soap, and leather. It is 445 miles from St Petersburg. Long. 38. 19. E. Lat. 57. 27. N.

UGOCSA, a circle of the Austrian kingdom of Hungary, in the province of the Hither Theiss. It extends over 480 square miles, one half of which is covered with woods. It comprehends three market-towns and sixty-three villages, with 5390 houses, and 36,900 inhabitants, mostly Catholics, with 2000 Protestants and 1500 Jews. The chief town is Nagyszollos, with 2160 inhabitants, whose chief trade is in wine. Long. 22. 44. 34. E. Lat. 48. 7. 10. N.

UIST, South and North, two of the Hebrides Islands. South Uist is situate in 57° 7′ and 57° 25′ N. lat., and 7° 12′ and 7° 28′ W. long. Its extent is twenty-one miles, its greatest breadth about eight miles and a half, and its superficial extent is calculated at 127 square miles. The population in 1831, including small islands attached to it, amounted to 6890. North Uist is separated from South Uist by the island of Benbecula. It is situate between 57° 40′ and 57° 48′ N. lat., and 7° 1′ and 7° 30′ W. long. It is of an irregular triangular shape, and has a length of nearly seventeen miles, a breadth of about twelve miles, and contains a superficial extent of 118 square miles. The population in 1831, including the island of Boreray, amounted to 4603. The rocks of both islands are gneiss, and both present nearly the same physical appearance, being broken up by innumerable branches of the sea, and having their surface covered by a multiplicity of fresh-water lakes, a few feet in depth, so as to render it difficult to determine whether water or land prevails. They are also completely destitute of wood, and the land may be said to be rather extensive series of peat-bogs and sand-levels, than of soil. In South Uist there are three distinct groups of hills, which exclusively occupy the eastern side, the highest of which is Heckla, rising to an elevation of 2940 feet; while the western division is a level tract of peat, which terminates, at the extreme west, in sand. Barley, oats, rye, and potatoes, are cultivated here, by the use of seaweed and the ordinary manure. Portions also of the middle tract are cultivated, where the ground is firm, and naturally drained by means of the lakes. North Uist also rises on its eastern side, towards the north, into a low ridge of hills, which gradually increase toward the south, till they rise to an elevation of 2000 feet. Westward from this there is a large brown, peaty, and boggy flat tract, comprising nearly half the area of the island, and producing scanty and wretched herbage. The south-west part however terminates in an uneven tract of good land, the soil of which contains clay; and this being aided by peat and drift seaweed, and mixed with sand, forms an excellent open mould, applicable to the cultivation of barley and potatoes. This forms the principal part of the arable land in North Uist. In both islands, however, the peat is undergoing a gradual amelioration toward mould, by the diffusion of the sand, formed for the most part of various comminuted shells, which is blown by the wind over the surface. The rearing and exporting of cattle, the fisheries, and the manufacture of kelp, which is now in a very depressed state, are the means by which the inhabitants earn their subsistence. There are various remains of military works and barrows found in North Uist. The population of the two islands being 11,493, and their superficial extent 245 square miles, the number of inhabitants for each square mile is forty-seven; while in the rest of Scotland the proportion is eighty-six to each square mile. Even this small number is too great for the unproductive state of the soil. The growing scarcity of fish, and the fearful over-population, have reduced the greater part of the inhabitants to a state of wretchedness. Education is in a very backward condition. In 1831 the number of well-educated persons was thirty-three, and the number of those above six years of age unable to read was 7400. In 1838 the number of schools was 15, and of scholars 590.

UJ-VIDEK, a city of the Austrian kingdom of Hungary, in the province of Hither Danube and the circle of Bacs. It is the capital of a district called by the Germans Neusatz, and by the Hungarians Also-Jaras. It stands on the river Danube, is the seat of a Greek bishop, and has five churches belonging to that sect, and one to the Catholics; and to each there are attached establishments for education. It contains 2367 houses, and 13,390 inhabitants, who are mostly of the Armenian race, and carry on extensive trade with the Turkish empire. Long. 19. 59. 26. E. Lat. 45. 16. N.

UKENSKOI, a town of Asiatic Russia, in the government of Tobolsk, at the confluence of the Irtysch and the Obi, 196 miles north of Tobolsk.

UKIKITSCHA, a small river of Irkoutsk, in Asiatic Russia, which falls into the Olenek.

UKINSKOI, a cape of Asiatic Russia, on the eastern coast of Kamtschatka, sixty miles north-east of Oudinskoi.

UKIPEN, a small island in the North Pacific Ocean, so called by the Russians, probably the same with that called Sledge Island by Captain Cook. Long. 214. E. Lat. 64. 22. N.

UKRAINE, a large country of Europe, lying on the borders of Turkey in Europe, Poland, Russia, and Little Tartary. Its name properly signifies a *frontier*. By a treaty between Russia and Poland in 1693, the latter remained in possession of all that part of the Ukraine lying on the west side of the river Dnieper, which is but indifferently cultivated; while the country on the east side, inhabited by the Cossacks, is in much better condition. The Russian part is comprised in the government of Kiof; and the empress of Russia having obtained the Polish palatinate of Kiof by the treaty of partition in 1793, the whole of the Ukraine, on both sides of the Dnieper, now belongs to that ambitious and formidable power. The principal town is Kiof. See Russia.

ULEABORG, the most extensive circle of the Russian province of Finland. It is bounded on the north by Norway, on the east by Archangel, on the south-east by Kupio, on the south by Wasa, on the south-west by the Gulf of Bothnia, and on the north-west by Sweden. It extends over 46,266 square miles, comprehending three towns, 1302 hamlets or farms, with 80,800 inhabitants. The capital is the city of the same name, situated at the mouth of the river Ulea. It has 360 houses, mostly of wood, and 3500 inhabitants, who build ships, and are employed in the export trade, which consists of tar, pitch, butter, tallow, wax, deals, and cured fish. The harbour is bad, being filled with sand, so that ships must load and discharge their cargoes four miles below the city. Long. 25. 24. 53. E. Lat. 64. 53. 30. N.

ULEY, a town of the hundred of Berkeley, in the county of Gloucester, two miles from Dursley and 105 from London. Near to it, on the side of a hill, are the remains of a Roman encampment. The chief occupation is making broad cloths for the East India market, which are afterwards dyed and finished in London. The population amounted in 1821 to 2655, and in 1831 to 2641.

ULIETEA, one of the Society Islands, in the South Pacific Ocean, wholly surrounded by reefs, and interspersed with small islands, forming several harbours. (For further details, see Society Islands.) The southern extremity is in long. 181. 20. W. and lat. 16. 55. S.

ULLAPOOL, a fishing village situate on the north shore of Loch Broom, in Ross-shire. It possesses an excellent harbour and quay; but the buildings, and, it must be added, the population, are quite disproportionate to the present state of its trade and fisheries. In the article Ross-shire, the quantity of fish caught and cured here since 1830 is stated. The population amounts to 500 or 600.

ULM, a city of the kingdom of Wurtemburg, the capital of a circle of the same name in the province of the Danube. It stands on the river Danube, at the point where the Iller and the Blau discharge their waters into that river, and the Danube thus becomes navigable. On the western side are some lofty hills, which were once crowned with fortifications, but when attacked, were found nsufficient means of defence, and whose capture in 1805 led o the disgraceful surrender of an Austrian army of 30,000 nen, under General Mack, to the French, commanded by Bonaparte. The town is divided by the rivers, over which are eight bridges. It is an ancient city, contains hree Lutheran and two Catholic churches, 1620 houses, nd 12,049 inhabitants. Some of the public buildings are emarkable, especially the cathedral, whose interior is very triking, being 417 feet in length and 160 in breadth. It is rnamented with a tower 340 feet in height. The propor- ons and construction are objects of great admiration. It furnished with an organ of extraordinary power, having 952 pipes. Some of the ancient paintings in it are fine pecimens of the skill of the Germans in that art at a ery early period. The stadthouse, with its mechanical ock and its paintings, is curious and interesting. The ade of Ulm has much declined from its former state when was one of the Hanse Towns. There is some trade down e Danube, and some barges are built here for that pur- se. There are some linen manufactories and some tanne- es; but the chief trade is in flour, which is ground at se- ral mills on the three streams that run through and unite the city. Horticulture is a favourite pursuit of the inha- tants, and furnishes the best of fruits and of culinary ve- tables. Long. 9. 53. 1. E. Lat. 48. 23. 45. N.

ULSTER, one of the four provinces into which Ireland divided. It consists of the northern portion of the island, d embraces the following counties: Antrim, Armagh, van, Donegal, Down, Fermanagh, Londonderry, Mo- ghan, and Tyrone. This province had anciently petty ngs of its own. It was subjected to the English in the gn of Henry II. by John de Courcy, the first who bore title of earl of Ulster: but it afterwards threw off the ke, and was never entirely reduced till the reign of James when great numbers of Scots, by his encouragement, nt and settled in it; and from them the greater part of present inhabitants of the province are descended.

ULTERIOR, in *Geography*, is applied to some part of ountry or province which, with regard to the rest of that ntry, is situated on the farther side of the river, moun- n, or other boundary which separates the two countries.

ULTRAMARINE, a beautiful blue colour used by the nters, prepared from the lapis lazuli by calcination.

ULTRAMONTANE, something beyond the mountains. e term is principally applied in relation to France and ly, which are separated by the Alps.

ULUGH-BEIGH, a learned Tartarian prince, was born 1393. His real name was Mohammed Taragai; Ulugh- igh being only a descriptive appellation, signifying great l or prince. His father was the sultan Shah Rok, the of the celebrated Timur, who, after the death of that queror, ruled many years in Iran and Turan, that is, sia and Tartary. In 1407, while his father was yet ng, he entered upon the administration of the govern- nt, and notwithstanding his youth, acquitted himself in h a manner as to acquire general esteem. He was a arkable person for the age in which he lived, and was ticularly distinguished by his skill in astronomy. The nination of his life was unhappy. His eldest son hav- rebelled against him, defeated him in a bloody battle ght near Samarcand. To this unworthy son he after- ds ventured to present himself, in the hope of re- ing his sense of duty; but such a hope was delusive, and son ordered him to be put to death. This event, ac- ding to D'Herbelot, took place in the year 1450. Of his ks, some portions have been printed. Greaves publish- ' Binæ Tabulæ Geographicæ, una Nassir Eddini, altera g-Beigi." Lond. 1648, 4to. These tables, in Arabic Latin, were reprinted in Dr Hudson's Geographiæ Veteris Scriptores Græci minores, tom. iii. Greaves likewise published, in the same language, "Epochæ celebriores, astronomis, historicis, chronologis, Chataiorum, Syro-Græcorum, Arabum, Persarum, Chorasmiorum usitatæ: ex traditione Ulugh-Beigi." Lond. 1650, 4to. From a collation of three Persic manuscripts, Dr Hyde edited "Tabulæ Longitudinis et Latitudinis Stellarum Fixarum, ex observatione Vlughbeighi." Oxon. 1665, 4to.

ULVERSTONE, a market-town in the hundred of Lonsdale, and county of Lancaster, 273 miles from London. It is pleasantly situate, and consists principally of four spacious and well-built streets. Its trade is considerable, is on the increase, and consists of ore, pig, and bar iron, copper ore, cotton, hats, and other fabrics. The trade has been greatly facilitated by the canal which communicates with the river Leven. There is a yard for ship-building. Besides the parochial church, there are places of worship for various bodies of dissenters. There is a good weekly market, and two fairs are held yearly. The population amounted in 1821 to 4315, and in 1831 to 4876.

ULYSSES, king of Ithaca, the son of Laertes and father of Telemachus, and one of those heroes who contributed most to the taking of Troy. After the destruction of that city, he wandered for ten years, and at last returned to Ithaca, where, with the assistance of Telemachus, he killed Antinous and other princes who intended to marry his wife Penelope and seize his dominions. He at length resigned the government of the kingdom to his son Telemachus, and was killed by Telegonus, his son by Circe, who did not know him. This hero is the subject of the Odyssey.

UMAN, a circle of the Russian government of Kiew, extending in north latitude from 48° 25′ to 49° 9′, and in east longitude from 29° 40′ to 30° 41′. It is separated from Cherson by the river Seniuska. It has little wood, but extensive steppes, producing, when cultivated, good crops of corn. The capital is of the same name, situated on the river Umanka. It is surrounded with walls, which furnish good promenades, contains a magnificent palace belonging to Count Potocksi, one Catholic and three Greek churches, 440 houses, and 3300 inhabitants. It is 1020 miles from St Petersburg. Long. 29. 51. E. Lat. 48. 43. N.

UMBELLIFEROUS PLANTS are such as have their tops branched and spread out like an umbrella.

UMBRELLA, a moveable canopy, made of silk or other cloth spread out upon ribs of whalebone, and supported by a staff, to protect a person from rain, or the scorching beams of the sun.

UMMERAPOOR, a large city, and the present capital of the Birman empire. It stands on the banks of a romantic lake, seven miles long by one and a half broad, and at a short distance from the Irrawaddy river. When the lake is filled during the periodical rains, it leaves, with the river on the other side, a peninsula, on which the city is built. It is a place of great resort, and of extensive trade; and the lake during the highest floods, when it is covered with numerous boats of every description, presents, with the lofty hills in the neighbourhood, an extraordinary spectacle to a stranger. The town is regularly fortified, and is laid out in an exact square. The streets are wide, and intersect each other at right angles. There are four principal gates, one on each side of the square, and a smaller gate on each side of the great gate. At each angle of the fort there is a large quadrangular bastion, which projects considerably; and there are also eleven smaller bastions on each side, including those over the gateway. Between each of these bastions is a curtain, extending 200 yards in length. The ditch of the fort is wide, and faced with brick. The rampart, faced by a wall of brick, is about twenty feet high exclusively of the parapet, which has embrasures for cannon and apertures for musketry. Small demi-bastions project at regular intervals; and the gates are massive, and guarded by cannon. The southern face of the fort is washed during the rainy season by the waters of the lake; and the houses of the city and suburbs extend along the bank as far as the extreme point of the land. The town is but meanly built. There are few houses of brick and mortar, and these belong to the members of the royal family. The houses of the chief persons are surrounded by a wooden enclosure; and all houses whatever are covered with tiles, and have on the ridge of the roof earthen pots filled with water, as a precaution against fires, which are here very frequent. When a fire takes place, they are immediately broken. In the centre of the town stands the royal palace, which consists of a number of wooden buildings of various forms, the domes of which, being covered with gilt copper, make a splendid appearance. The whole is surrounded with an enclosure of teak plants, having four gates, and may be half a mile in circumference. The splendour of the religious buildings is very striking, owing to their being entirely covered with gilding, the inside of the roofs as well as the outside. The gold leaf that is used, being exceedingly pure, bears exposure to the air for a long time without suffering injury. The royal library is situated at the north-west angle of the fort, in the centre of a court paved with broad flags. The books are kept in wooden chests curiously ornamented. The chests are about 100 in number, and well filled. The contents of each chest are inscribed in gold letters on the lid. The city is divided into four distinct quarters, each of which is governed by its own officer; and no town in Europe can boast of a better police. Ummerapoor was founded by the Birman monarch Minderajee Praw, so recently as 1783, about four miles east from old Ava, the ancient capital. Buildings in this part of India being mostly composed of wood, and the river presenting a convenient water-carriage, the present capital rose most rapidly, and became in a short time one of the most flourishing and well-built cities in the east. The population was estimated by Captain Cox at 175,000 persons, and the number of houses from 20,000 to 25,000. Long. 96. 7. E. Lat. 21. 55. N.

UMNABAD, a town of Hindustan, in the province of Bejapoor, thirty miles north-east from Poonah. Long. 74. 27. E. Lat. 18. 51. N.

UMRUT, a town of Hindustan, in the province of Aurungabad, forty miles south by east from Surat. Long. 73. 18. E. Lat. 20. 40. N.

UNBIAK, one of the Fox Islands, in the North Pacific Ocean, about seventy-two miles in circumference.

UNCIA, a Latin term, denoting the twelfth part of any thing, particularly the twelfth part of a pound, called in English an *ounce*, or the twelfth part of a foot, called an *inch*.

UNCTION, the act of anointing or rubbing with oil or other fatty matter.

Unction, in matters of religion, is used for the character conferred on sacred things by anointing them with oil. Unctions are very frequent among the Hebrews. They anointed both their kings and high priests at the ceremony of their inauguration. They also anointed the sacred vessels of the tabernacle and temple, to sanctify and consecrate them to the service of God. The unction of kings is supposed to be a ceremony introduced very late among the Christian princes. It is said that none of the emperors was ever anointed before Justinian or Justin. The emperors of Germany borrowed the practice from those of the eastern empire. King Pepin of France was the first who received the unction. In the ancient Christian church, unction always accompanied the ceremonies of baptism and confirmation. Extreme unction, or the anointing persons in the article of death, was also practised by the ancient Christians, in compliance with the precept of St James, v. 14, 15; and this extreme unction the Romish church has advanced to the dignity of a sacrament. It is administered to none but such as are affected with some mortal disease, or in a decrepit age. It is refused to impenitent persons, as also to criminals. The parts to be anointed are the eyes, the ears, the nostrils, the mouth, the hands, the feet, and the reins. The laity are anointed in the palms of the hands, but priests on the back of them; because the palms of their hands have been already consecrated by ordination. The oil with which the sick person is anointed represents the grace of God, which is poured down into the soul, and the prayer used at the time of anointing expresses the remission of sins thereby granted to the sick person; for the prayer is this: "By this holy unction, and his own most pious mercy, may the Almighty God forgive thee whatever sins thou hast committed *by the sight*," when the eyes are anointed; *by the hearing*, when the ears are anointed; and so of the other senses.

UNDECAGON is a regular polygon of eleven sides.

UNDECEMVIR, a magistrate among the ancient Athenians, who had ten colleagues or associates joined with him in the same commission. The functions of the undecemviri at Athens were much the same with those of the late *prevôts de maréchaussée* in France. They took care of the apprehending of criminals; secured them in the hands of justice; and when they were condemned, took them again into custody, that the sentence might be executed on them. They were chosen by the tribes, each tribe naming its own; and as the number of the tribes after Callisthenes was but ten, which made ten members, a scribe or notary was added, which made the number eleven.

UNDES, an extensive district of Northern Hindustan, bordering on Little Tibet, intersected by the river Sutelege. The mountains of the country are composed of granite, and are said to be rich in gold. It is subject to the lama of Tibet.

UNDULATION, in *Physics*, a kind of tremulous motion or vibration observable in a liquid, by which it alternately rises and falls like the waves of the sea.

UNICORN, an animal famous among the ancients, and thought to be the same with the rhinoceros. Sparmann informs us that the figure of the unicorn described by the ancients has been found delineated by the Snese Hottentots on the plain surface of a rock in Caffraria, and therefore conjectures that such an animal either does exist at present in the interior parts of Africa, or at least once did so. Father Lobo affirms that he has seen it. Sir John Barrow, in his Travels in Southern Africa, affords additional reason to believe in the existence of this curious animal.

UNIEH, a seaport of Asia Minor, on the coast of the Black Sea, situated on a bay, with a range of finely wooded mountains behind. It is mostly built of wood, and, like all eastern towns, is extremely filthy; forming a striking contrast with the beauty of the environs. The inhabitants consist of Turks, Greeks, and Armenians, who carry on a considerable trade with Constantinople and the Crimea. Its exports are cotton stuffs from Tocat and Diarbekir, fruits, and wine; the imports corn and oil from the Crimea, coffee, sugar, and European manufactures from Constantinople. A number of vessels belongs to the port, though none of them exceeds 200 tons burden. Unieh is forty miles east of Samsoon.

UNION, a junction, coalition, or assemblage of two or more different things in one.

Union, or *The Union*, by way of eminence, is more particularly used to express the act by which the two separate kingdoms of Scotland and England were incorporated into one, under the title of the kingdom of Great Britain. This union, in vain attempted by James I., was at length effected in the year 1707, 6 Ann. when twenty-five articles were agreed to by the parliaments of both nations; the purport of the most considerable being as follows:

1. That on the first of May 1707, and for ever after, the kingdoms of England and Scotland shall be united into one kingdom, by the name of *Great Britain*. 2. The succes-

on to the monarchy of Great Britain shall be the same as before settled with regard to that of England. 3. The united kingdom shall be represented by one parliament. There shall be a communication of all rights and privileges between the subjects of both kingdoms, except where it is otherwise agreed. 9. When England raises L.2,000,000 by a land-tax, Scotland shall raise L.48,000. 16. 17. The standards of the coin, of weights, and of measures, shall be reduced to those of England throughout the united kingdoms. 18. The laws relating to trade, customs, and the excise, shall be the same in Scotland as in England. All the other laws of Scotland shall remain in force, but alterable by the parliament of Great Britain; yet with this caution, that laws relating to public policy are alterable at the discretion of the parliament; laws relating to private right are not to be altered but for the evident utility of the people of Scotland. 22. Sixteen peers are to be chosen to represent the peerage of Scotland in parliament, and forty-five members to sit in the House of Commons. 23. The sixteen peers of Scotland shall have all privileges of parliament; and all peers of Scotland shall be peers of Great Britain, and rank next after those of the same degree at the time of the union, and shall have all privileges of peers, except sitting in the House of Lords, and voting on the trial of a peer.

These are the principal of the twenty-five articles of union, which are ratified and confirmed by statute 5 Ann. cap. 8, in which statute there are also two acts of parliament recited; the one of Scotland, whereby the church of Scotland, and also the four universities of that kingdom, are established for ever, and all succeeding sovereigns are to take an oath inviolably to maintain the same; the other of England, 5 Ann. c. 6, whereby the acts of uniformity of 1 Eliz. and 13 Car. II. (except as the same had been altered by parliament at that time), and all other acts then in force for the preservation of the church of England, are declared perpetual; and it is stipulated, that every subsequent king and queen shall take an oath inviolably to maintain the same within England, Ireland, Wales, and the town of Berwick-upon-Tweed. And it is enacted, that these two acts "shall for ever be observed as fundamental and essential conditions for the union."

Upon these articles and act of union, it is to be observed, 1. That the two kingdoms are so inseparably united, that nothing can ever disunite them, except the mutual consent of both, or the successful resistance of either, upon apprehending an infringement of those points which, when they were separate and independent nations, it was mutually stipulated should be "fundamental and essential conditions of the union." 2. That whatever else may be deemed "fundamental and essential conditions," the preservation of the two churches of England and Scotland, in the same state that they were in at the time of the union, and the maintenance of the acts of uniformity which established the liturgy, are expressly declared so to be. 3. That the municipal laws of Scotland are ordained to be still observed in that part of the island, unless altered by parliament; and as the parliament has not yet thought proper, except in a few instances, to alter them, they still, with regard to the particulars unaltered, continue in full force.

For an account of the union of Ireland with Great Britain, thus forming the united kingdom of Great Britain and Ireland, see BRITAIN.

UNITARIANS, a name given to those who confine the glory and attribute of divinity to the One only great and supreme God, and Father of our Lord Jesus Christ.

UNITED BRETHREN, or *Unitas Fratrum*, a society of Christians, whose chief residence is at Herrnhut, in Saxony. They are commonly called Moravians, from their original country, and Herrnhuters, from their chief place of residence. Some account of this society has already been given under HERRNHUT; but as that account may not be deemed sufficiently full, we shall here add a summary of their institutions, derived from a communication by one of their own clergy.

Though the church of the United Brethren is episcopal, their bishops possess no elevation of rank or pre-eminent authority, their church being governed by synods or consistories from all the congregations, and by subordinate bodies called conferences. The synods are generally held once in seven years. In the first sitting a president is chosen; and the elders appointed by the former synod to superintend the unity lay down their office, though they still form a part of the assembly, as well as the bishops, the lay elders, and those ministers who have the inspection of several congregations in one province. Questions of importance, or of which the consequences cannot be foreseen, are decided by lot, though this is never used till after mature deliberation and fervent prayer. In the synods, the state of the unity, and the concerns of the congregations and missions, are taken into consideration. Towards the conclusion of every synod, a kind of executive board is appointed, called the elders' conference of the unity, consisting of thirteen elders, and divided into four committees or departments, one for superintending missions into heathen countries, a second for watching over the conduct of congregations, a third for managing the economical concerns of the unity, and a fourth for maintaining the discipline of the society. These conferences are however amenable to a higher committee, called the elders' conference, the powers of which are very extensive. It appoints and removes every servant in the unity, authorizes the bishops to ordain presbyters or deacons, and to consecrate other bishops, and, in short, possesses the supreme executive power over the whole society.

A bishop of the United Brethren can discharge no office but by the appointment of the synod or of the elders' conference. Indeed their deacons can perform every office of the bishops except ordination, and appear to confirm young persons when they first become candidates for the communion. Deaconesses are employed for the purpose of privately admonishing their own sex, and visiting them in cases of sickness. There are also lay elders, whose business it is to watch over the constitution and discipline of the unity, to enforce the observance of the laws of the country in which missions are established, and to guard the privileges conferred on the brethren by the government under which they live.

On Sunday, besides the public prayers, one or two sermons are preached in every church; and after the morning service, an exhortation is given to the children. Previously to the holy communion, which is administered on some Sunday once a month, and on Maunday Thursday, each person, before he communicates, must converse on the state of his soul with one of the elders. Love-feasts are frequent; and on Maunday Thursday the society have a solemn footwashing.

Our limits will not permit us to give a systematic view of the doctrinal tenets of the Brethren. Though they acknowledge no other standard of truth than the sacred Scriptures, they adhere to the Augsburg Confession, and speak respectfully of the thirty-nine articles of the church of England. They profess to believe that the kingdom of Christ is not confined to any particular party, community, or church; and they consider themselves as spiritually joined in the bond of Christian love to all who are taught of God, and belong to the universal church of Christ, however much they may differ in forms, which they deem non-essentials. For a fuller account of this society, see Crantz's Ancient and Modern History of the Protestant Church of the United Brethren, London, 1780; and An Exposition of Christian Doctrine, as taught in the Protestant Church of the United Brethren, London, 1784.

UNITED PROVINCES. See HOLLAND and NETHERLANDS.

UNITED STATES OF NORTH AMERICA.

No single event in modern history has been of so much importance to mankind as the discovery of America. That great continent, which had been hid from the eyes of civilized nations for so many ages, comprises nearly one third of the habitable globe. In soil and climate it rivals the best parts of the old continent. It is not, like Asia and Africa, infested by the larger and more dangerous species of wild animals, nor deformed by vast deserts, which present insuperable obstacles to civilization. But its great and peculiar advantage lies in the unrivalled magnitude and number of its navigable rivers, which enable its most remote inland parts to hold commercial intercourse with each other, and with foreign states, with unparalleled ease and rapidity. The position of these great rivers, whose estuaries all open to the east, points out the western side of the old continent as the region with which it is destined by nature to be most closely connected. Two great classes of colonists, widely dissimilar in character and in circumstances, came from Europe to occupy this new world. The Spaniards, who were first in the order of time, took possession of the most populous and fertile regions; but their natural advantages were rendered abortive by political and moral evils, a rapacious spirit, a corrupt religion, and a vicious system of government. The English, the other great class of colonists, owed their better fortunes in some measure to their apparent disadvantages. Having neither gold mines to work, nor wealthy Indians to rob, they cultivated with greater diligence the natural riches of the soil, and laid the foundation of future prosperity in habits of order and industry. Neglected by the government as a band of destitute refugees, they enjoyed what was then an unusual degree of civil and religious liberty. Their industry flourished, because it was unfettered and unburdened. They were well governed, because they were left to govern themselves. And if they wanted the aid of the mother country when that aid might sometimes have been useful, they were, on the other hand, exempted from those incessant exactions and vexations to which the Spanish colonists were exposed, from the ignorant, meddling, grasping, bigoted spirit of their European rulers. The troubles which they experienced from the hostility of the Indians diminished as their own numbers increased, and, except at first, were never extremely detrimental. Their common dangers served in some measure as a bond of union among themselves, and perhaps favoured their social improvement, by acting as a slightly compressing force to prevent the indefinite diffusion of the population over a large surface. To their free spirit, virtuous habits, intelligence, and industry, the English colonists certainly owed much of their early success; but we must not forget that a series of fortunate changes, not directly the consequence of their own exertions, has greatly contributed to place them in the enviable situation which they now occupy. Had the Dutch, French, Danish, and Swedish colonies planted in North America spread as fast and as far as those of England, and continued separate and independent, we should have seen, in the space between the Mississippi and the Atlantic, the same medley of nations and languages, with the same diversity of manners, religion, institutions, and clashing interests, which foster everlasting feuds and jealousies in Europe, engender desolating wars, load the people with oppressive taxes and military tyrannies, and present a formidable barrier to the circulation of knowledge and the progress of society. The conquests of England, which blended all these colonies into one nation, have secured to the United States an exemption from half the evils which afflict civil society in Europe, and have prepared for them a career of peaceful grandeur and growing prosperity, which divided Europe cannot hope to enjoy, and which has had no parallel in the history of mankind. The people of the United States find themselves in a condition to devote their whole energies to the cultivation of their vast natural resources, undistracted by wars, unburdened by oppressive taxes, unfettered by old prejudices and corruptions. Enjoying the united advantages of an infant and a mature society, they are able to apply the highly refined science and art of Europe to the improvement of the virgin soil and unoccupied natural riches of America. They start unencumbered by a thousand evils, political and moral, which weigh down the energies of the Old World. The volume of our history lies before them: they may adopt our improvements, avoid our errors, take warning from our sufferings, and, with the combined lights of our experience and their own, build up a more perfect form of society. Even already they have given some momentous and some salutary truths to the world. It is their rapid growth which has first developed the astonishing results of the productive powers of population. We can now calculate, with considerable certainty, that America, which yet presents to the eye, generally, the aspect of an untrodden forest, will, in the short space of one century, surpass Europe in the number of its inhabitants. We even hazard little in predicting, that, before the tide of civilization has rolled back to its original seats, Assyria, Persia, and Palestine, an intelligent population of two or three hundred millions will have overspread the New World, and extended the empire of knowledge and the arts from Cape Horn to Alayska. Among this vast mass of civilized men there will be but two languages spoken. The effect of this single circumstance in accelerating the progress of society can scarcely be calculated. What a field will then be opened to the man of science, the artist, the popular writer, who addresses a hundred millions of educated persons? what a stimulus given to mental energy and social improvement, when every new idea, and every useful discovery, will be communicated instantaneously to so great a mass of intelligent beings, by the electric agency of the post and the press? With the united intellect and resources of a society framed on such a gigantic scale, what mighty designs will then be practicable? Imagination is lost in attempting to estimate the effects of such accumulated means and powers. One result may however be anticipated. America must then become the centre of knowledge, civilization, and power; and the present leading states of Europe (Russia perhaps excepted), placed on the arena amidst such colossal associates as the American republics, will sink to a subordinate rank, and cease to exert any greater influence on the fate of the world than the Swiss cantons do at the present day.

The territory of the United States is situated between the 25th and 49th degrees of north latitude, and between the 67th and 124th degrees of west longitude from London. Its extreme length east and west is 2780 miles, its greatest breadth north and south 1230 miles, and its area, according to Mr Mellish, 2,076,410 square English miles. It is bounded on the east by the Atlantic Ocean, on the north by the British possessions, on the west by the Pacific Ocean, and on the south by Mexico and the Mexican Gulf. The Mississippi divides it into two parts nearly equal in extent. In the north-east angle of this territory, there is a space of more than 100 miles square, of very barren ground, interposed between New Brunswick and Lower Canada, the possession of which has long been the subject

United States.

negociation between the British and American governments. On the west coast the Americans have an unquestioned claim to the country, between the 42d and 47th parallels; but Russia disputes the right of possession with them to the tract of country between the 49th and 60th parallels. As the admitted boundaries are in general very distinctly marked on the common maps, we shall not describe them in detail.

Two chains of mountains separate this extensive territory into three great natural divisions. 1. The Atlantic region, or the country lying east of the Alleghany Mountains. 2. The valley of the Mississippi, or the country watered by the Mississippi, Missouri, and their numerous branches. 3. The Pacific region, or the country lying west of the Rocky Mountains.

The Alleghany Mountains commence in Lower Canada, below Quebec; and passing along the northern boundary of Maine, and through New Hampshire, Vermont, New York, Pennsylvania, Virginia, and the two Carolinas, they terminate in the upper parts of Georgia and Alabama, preserving a south-west direction throughout. They consist of three, four, five, or more distinct ridges, with wide and fertile valleys interposed. Their entire length is 1100 miles, their breadth varies from 110 to 150. In the northern half their height is greatest, but most unequal; detached peaks are numerous, and the ridges indistinctly marked. In the south, the ridges are lower, but better defined, and their summits are often distinguished by a very uniform continual level. They attain their greatest height in New Hampshire, where Mount Washington has an elevation of 6600 feet. Their greatest height in New York is 3800, in Pennsylvania 2500, in Virginia 3900, in South Carolina 4000. The mean height is said by Mr Mellish to be from 1000 to 1800 feet, but his average is undoubtedly formed on wrong principles. That of the highest chain cannot be less than from 2000 to 2500 feet.[1]

The Rocky Mountains, known but imperfectly, are a continuation of the Mexican Cordilleras, and extend to the Polar Ocean. They pass through the territory of the United States, at the distance of 500 miles from the Pacific Ocean, and consist of several elevated chains, occupying a breadth of 300 miles, with deep valleys between them. They rise abruptly from their base, and are supposed to reach the elevation of 12,000 feet in their highest summits, many of which are covered with perpetual snow. There are, however, several passes through them, which, with a little improvement, might be traversed by loaded waggons.[2]

The *Atlantic Region* was the first settled, and is the most populous and improved portion of the United States, but not the most favoured as to soil and climate. It may be considered as the eastern slope of the Alleghanies. Including all the countries watered by rivers flowing into the Atlantic and the Gulf of Mexico, east of the Mississippi, it is about 1700 miles in length, with an average breadth of 200, and embraces an area of 400,000 square miles. It includes three well-marked varieties of soil and surface. 1. The alluvial district, consisting of sand, gravel, and clay, comprising a stripe of level land, extending along the coast from New York southward, with a breadth varying from twenty miles to 100. The surface is level or slightly undulating, and it embraces large tracts of marsh near the coast. The soil is poor and sandy, producing almost nothing but pines, except in the alluvial tracts which skirt the rivers. About one half of the surface of New Jersey, Delaware, and Maryland, one fifth of Virginia, one third of the Carolinas, Georgia, Florida, and Alabama, fall under this description. 2. The upland country, extending from the alluvial tract to the foot of the mountains, with a breadth varying from twenty to 200 miles. Here the soil is chiefly formed from the detritus of the primitive rocks, and is generally fertile, and well adapted for tillage. 3. The ridges of the Alleghanies, and the valleys between them, which bear a strong growth of natural wood, have generally a rich soil, capable of tillage, wherever the surface is not rocky or too steep; and are almost free from marshes. In part of Pennsylvania, New York, and in the six New England States,[3] where the Alleghanies spread out into an irregular broken surface, the soil possesses a mixed character. The northern parts of New England are mountainous, the southern hilly or uneven. The soil, comparatively speaking, is rocky, has little depth, and is better adapted for pasture than tillage, and improves generally as we advance inwards from the coast. The south-east section of New York corresponds in character with New England. But, of all the old states, Pennsylvania contains the largest portion of good soil on the east side of the mountains. The woods originally covered all this Atlantic region, except some tracts called the American *prairies*, on which, from causes not well explained, no natural growth of timber exists. These are not meadows or wet grounds, as the French term might be supposed to indicate; but lands bare of wood, whether wet or dry, level or uneven. As the population thickens, the forests disappear; but even in the most densely peopled parts, the woodlands occupy so large a proportion of the surface, that the country generally presents, to the eye of a European, the aspect of a natural wilderness, broken by patches of cultivation, which are numerous round the great cities, but grow less frequent as we recede from the shore, till they terminate in the boundless forests of the Alleghanies.

Valley of Mississippi.

The basin or *Valley of the Mississippi*, which extends from the Alleghanies to the Rocky Mountains, is not so large by one third as the basin of the Amazon, but being situated in the best part of the temperate zone, it may be pronounced the finest valley in the world. Its breadth east and west is 1400 miles; its length in the opposite direction 1200, and its area 1,400,000 square miles. It comprehends a great diversity of soil, surface, and climate. 1. The basin of the Ohio, including the Cumberland, 700 miles long and 300 broad, is a rich and beautiful country, the garden of the United States. The lower parts of the surface are from 500 to 800 feet above the level of the sea, and are finely diversified with round-topped arable hills, rising 400 or 500 feet above their base. The rivers generally run in deep hollows, sometimes mere ravines, but often spreading out into valleys, which include lands of exuberant fertility. This district includes Kentucky, Tennessee, with part of Virginia, Pennsylvania, Ohio, Indiana, and Illinois. 2. The territory extending from the basin of the Ohio north-westward to Lake Superior, including the country between the Missouri and Upper Mississippi. The surface is sometimes undulating, sometimes so level that the waters stagnate on it, till carried off by evaporation; nor is it broken by any notable elevations, except one long ridge extending between the Missouri and Mississippi, and two low eminences called the Ocooch and Smoky Mountains. The soil is naturally rich, and covered with luxuriant herbage; but the climate is severe, and the woods so thin that the bare ground or prairies occupy three fourths of the surface on the east side of the Mississippi, and nineteen twentieths on the west.

---

[1] Mellish's Geographical Description of United States, Philadelphia, 1822, p. 20. Warden's Statistical, Political, and Historical Account of the United States, 1819. Introduction.

[2] Mellish, p. 21. James's Account of an Expedition from Piltsburg to the Rocky Mountains in 1819, 1820, vol. iii. p. 238. Warden, iii. 161.

[3] As the name of New England occurs often in American books, it may be proper to mention, that the appellation is applied to the six states east of the Hudson,—Connecticut, Rhode Island, Massachusetts, Vermont, New Hampshire, and Maine.

The absolute elevation of the northern parts is probably not under 1500 feet, for Cassina lake, thirty miles below the sources of the Mississippi, is 1330 feet above the sea. (Mellish, p. 32. James's Expedition, iii. 204.) 3. The last and largest division of this great valley, extending from the Mississippi and Missouri to the Rocky Mountains, consists of two very different qualities of soil, which graduate into each other, but, on the great scale, may be conceived to form two parallel tracts of nearly equal extent, parted by the 98th meridian. In the middle of the eastern section, and, as it were, in the very bottom of the great basin of the Mississippi, lie the Ozark Mountains; a chain, like the Alleghanies, of great length and breadth, and small height, rising only from 1000 to 2000 feet above the sea. (James's Expedition, iii. p. 313.) Mr Mellish erroneously calls the height 3500 feet. Their breadth is from 100 to 150 miles: their sides, which slope with gentle declivities, are deeply furrowed with streams, and partly covered with small timber. The Arkansas and Red River are the only streams which cut their way through this chain. On the east side of the Ozark chain is the Great Swamp, 200 miles long and twenty broad, which is converted into a lake by the annual overflow of the Mississippi, but is dry during the heats of summer, and rendered impenetrable at all times by a thick growth of cypress. The country round it is rich bottom or meadow land, clothed with excellent timber. The country for one or two hundred miles west of the Ozarks is also good, but less wooded; and in the eastern section, taken altogether, the open ground occupies nineteen twentieths of the surface. The western section, extending from the meridian of 98° to the Rocky Mountains, is comparatively dry and sterile, and much of it an absolute desert, destitute of herbage, and unfit for human habitation. As we approach the mountains, the ground, which is at first hilly, subsides into smaller undulations, and these terminate in table-lands, nearly flat on the top, with steep, and sometimes precipitous sides, and rising 600 or 800 feet above the common level. These table-lands, consisting of alternate beds of sandstone and breccia, increase in number and diminish in extent as we approach the base of the mountains, which is believed to have an elevation of 3000 feet above the sea. The desert aspect of the country, however, is not the effect of its elevation, but more probably of its aridity; for valleys among the mountains, which are still higher, are fertile. The rivers in this frightful solitude often spread out to a breadth of one or two miles, and dry up in the warm weather. Salt springs are numerous, and salt incrustations cover many square miles. Trees are only to be seen at some spots along the rivers, and are rather more abundant in the south than in the north; but throughout the whole section, the wood does not cover the thousandth part of the surface. Of the basin of the Mississippi altogether, it may be observed, that the western side is a barren desert; the middle contains much good lands, but abounds in swamps; the east side, comprehending the basin of the Ohio, is the richest, and most eligible for human habitation. The woods, in their natural state, increase continually as we advance from the Rocky Mountains to the Atlantic; a proof, perhaps, that the summer heat, and the quantity of atmospheric moisture, follow a similar law.[1]

Pacific region.

The *Pacific Region* extends from the Rocky Mountains to the ocean, and (exclusive of disputed ground) from latitude 42° to 49°, embracing an area of 300,000 square miles. It consists almost entirely of the basin of the Columbia river.

The district of Oregan.

This country naturally divides itself into three parts, the first of which commences at the coast of the Pacific, and extends inland to a range of mountains running parallel with the coast, south-east and north-west, through which the Columbia river passes, and enters the sea in lat. 46° 19′ N. and in long. 124° W. These mountains lift their bold summits several thousand feet from their bases, but from their mid distance upwards their barren sides present the naked deformity of rocks, lava, and cinders. Their elevated summits appear to be the craters of extinguished volcanoes. Some of the high snowy peaks of this range are seen far at sea on the Pacific Ocean. The extent of this tract from west to east is about 130 miles, and southward to the limits of California, and probably very far north. The climate is remarkably moist, almost uninterrupted rain falling from October to April. In winter the weather is clear and the cold moderate. The temperature is mild and equable, resembling that of France and Spain much more than that of the Atlantic coast. Snow is seldom seen at the mouth of the Columbia river, so that ploughing could be carried on through most winters. This region contains a great proportion of barren inaccessible land; but the water-courses, which are numerous, afford valleys that are as fertile as can be found in the United States. The immediate sea-board is the worst part. For farming purposes, the level country may be upon the whole reckoned equal to any part of the state of New York. One half is of excellent quality, the other half inaccessible mountains.

The second division extends from the mountains, embracing the lower course of the Columbia, including its great falls, and eastward to the Blue Mountains, a higher range, about 168 miles. The temperature differs little from that of New England; the snows are light, and do not last long, seldom so long as to obstruct the feeding of animals. Little rain falls in summer in this division; about the middle of October there are usually rains, but not heavy. In this division of country the river-bottoms are neither so frequent nor so extensive as in the first, but at the foot of the mountains bounding each side of the valley, there are large tracts very fertile.

The third division extends from the Blue Mountains on the west to the Rocky Mountains eastward, a distance of about 286 miles, and presents wide sandy deserts, almost destitute of water. The deposits of vegetable matter are few, and there is very little moisture except near the rivers; and thousands of acres are white with Epsom and Glauber salts. In this valley is the great salt lake, on the bottom of which, when low, the salt is deposited as in a salt-pan. The climate is remarkable for dryness, and for the difference between the temperature during the night and the day. Not a cloud will be seen in the sky for six weeks, and no rain falls except for a few days in the spring, nor is there much snow in winter. A traveller mentions, that on the 18th August 1832 the thermometer at sunrise was as low as 18°, a depression which it seldom reaches in Great Britain, and on the same day was at 92°. A difference of 40° between sunrise and noon is not uncommon. On the Columbia river, about eighty miles from its mouth, the two great companies of Canadian traders, who in 1821 were formed into the North-West Company, established a settlement and the fort of Vancouver, which has since become the centre of the fur trade. It has been gradually improved, and the cultivators, clerks, factors, and traders who reside here amount to about 2000 souls. In 1835, they produced 8000 bushels of wheat, 5500 bushels of barley, 6000 of oats, 9000 of pease, 14,000 of potatoes, besides large quantities of vegetables. There is also a thriving orchard, in which are produced abundantly, apples, quinces, pears, and grapes. A large ship annually arrives from London with goods, and a trade is also carried on with the Sandwich and other of the South Sea Islands. There are other stations occupied by the North-West Company's servants; namely, at Wallawallah, 250 miles above Vancouver, and at

---

[1] This account of the basin of the Mississippi is entirely taken from Major Long's Memoir, published in the third volume of James's Account of the Expedition to the Rocky Mountains.

Colville, 600 miles higher. There are several other posts along the upper course of the river. These are generally picketed enclosures, occupied by from fifteen to twenty servants of the North-West Company, for the purpose of trading with the Indians for furs. They have at Vancouver a large thrashing machine, a saw-mill, a distillery, a grist-mill, and, in short, all the necessary rudiments of a civilized community.[1]

In 1835 a settlement was made on the river Wallamete, by a missionary of the name of Lee, which succeeded well. During the first year, a good crop was raised of green pease and other vegetables. A school was established, at which native children were instructed in reading and in all mechanical arts. The state of this country was brought under the consideration of the Congress by a petition from different settlers, who were intending to emigrate to it, and there to establish a colony. They requested the countenance of the government, and the aid of a military force with which to maintain law and order; and an estimate was made of the expense of a battalion of troops, and the necessary stores for that purpose.[2] This colony, the germ of a new state, has in this manner been established; the sovereignty of the country, obtained by the United States, will be duly maintained; and the seeds of population, planted in the congenial soil, will increase and multiply; and thus the desert will rejoice in a new and flourishing off-set from the great trunk of the American population.

The active population of the United States is rapidly spreading over the desert that lies to the westward of the cultivated portion of the United States, and the annual purchases of land bring a valuable addition to the revenue. The following is an account of the annual quantity of land that has been sold since the year 1820.

Years.	Quantity of Public Land offered for Sale.	Quantity of Public Land Sold.	Amount paid by Purchasers.
	Acres and 100ths.	Acres and 100ths.	Dollars.
1820	8,338,675 94	303,404·09	424,962·26
1821	10,919,480·42	781,213 32	1,169,224 98
1822	9,602,931 37	801,226·18	1,023,267 83
1823	11,414,598·70	653,319·52	850,136·26
1824	7,294,186·48	749,323 04	953,799·03
1825	3.419,604·55	893,461·69	1,205,068·37
1826	2,880,703·56	848.082·26	1,128,617 27
1827	3,314,816·71	926,727·76	1,318,105 36
1828	3,268,493·96	965,690·36	1,221,357 99
1829	6,148,962·26	1,244,860 01	1,572,863 54
1830	6,750,798·77	1.929,733·79	2,433,432·94
1831	11,005,561·42	2,777,856 88	3,557,023 76

The main flood of the American population is now rapidly making its way across the extended plains to the west of the Mississippi; numbers of adventurous emigrants are already settled in these western regions; the desert is rapidly assuming the aspect of cultivation, villages and towns supplanting the primeval forest; and in a few years the wild animals and the savage will alike disappear before the rapid progress of civilized man. The interminable woods of the west, and the inundations and marshes of the south, yield alike to the resistless sway of persevering energy; the great mass moves onward with increasing force, under the impulse of causes which no longer brook control, and which will no less bear down, it is to be feared, moral right than physical obstacles in its progress to the barrier of the ocean. Since the adventurous journey of Lewis and Clarke to the mouth of the Columbia river, the settlements have advanced farther to the west, and new and easier roads have been found across the wilderness and the Rocky Mountains, and down the great river of the Pacific. This country, the abode of wild animals, has been for more than twenty years a noted resort of the fur traders, and especially those in the service of the North-West Company.

Climate.

The United States, whose territories almost touch the tropic on the one side, and reach to districts where frost lasts five or six months on the other, embrace greater varieties of climate than any other single state in the world. Generally speaking, the climate of the United States is distinguished from that of Europe by three peculiarities. 1. It is absolutely colder for the corresponding degrees of latitude, the mean temperature of the year, according to Humboldt, being nine degrees of Fahrenheit lower on the east coast of America than on the west coast of Europe at the latitude of 40°, and 12½° lower at the latitude of 50°. 2. The thermometer has a greater range, as the heat of summer and the cold of winter reach greater extremes. 3. The climate changes more rapidly as we proceed from south to north, or a greater variety of climates is comprised within the same range of latitude. The mean temperature of Quebec, at one extremity, is 42°, and of Cape Sable, at the other, 72·7°. Between the parallels of 38 and 50, a degree of latitude which makes a change of 1·13° (Fahrenheit) in Europe, makes a change of 1·57° in the United States; and the same annual temperature which is found at a given degree of latitude in the United States, is found seven degrees farther north in Europe. The seasons are also differently distributed. Philadelphia, for instance, has the summers of Rome and the winters of Vienna. In Florida, at New Orleans, and at St Mary's in Georgia, snow is never seen; but in Pennsylvania snow lasts three months, in Massachusetts four, and in Maine five.[3] In the two latter states, the ice bears loaded waggons, and the sea is sometimes frozen to a considerable distance from the coast. In all the low country, from Florida to the St Lawrence, the extreme summer heat is nearly the same, from 90° to 98°, and the varieties of climate are chiefly marked by the intensity and duration of the winter's cold. The climate in the basin of the Ohio, compared with that of the Atlantic coast, possesses no very striking peculiarities, but seems, on the whole, to have its mean annual heat a little higher, to be rather more steady and equable, to be less frequently visited by the frigorific north-west winds, and to have fits of cold weather almost equally severe, but more transitory. The great lakes appear to mitigate the winter cold in the country immediately around them, and probably in the basin of the Ohio too; for on the west and north-west of this district the climate is much more rigorous. At Council Bluffs, on the Missouri, in latitude 41½°, the thermometer descends to —22° in winter, and rises to 105° in summer. At St Peter's Fort, on the Mississippi, in latitude 45°, it ranges from 92° to —30°, and the mean temperature of January is about zero. The absolute height of the fort, which cannot exceed 1000 feet, does not account for this excessive cold. We have already mentioned the equable temperature of the basin of the Columbia; and, from the observations made on the Missouri and Upper Mississippi, we have reason to believe that the mildest and the most rigorous winters known in any similar latitude are to be found at once on the opposite sides of the great rampart of the

Rocky Mountains. (On the subject of Climate, see Mellish, p. 59–77.)

Rain and winds.

So many local circumstances affect the annual depth of rain, that little reliance can be placed on general estimates. We find that it was forty-two inches at Charlestown, on an average of some years, forty at Natchez, thirty at Philadelphia, thirty-six at Cincinnati. The mean fall of rain for the inhabited part of the United States (latitude 41°) should be about thirty-four inches. The frequent failure of the streams, and the scarcity of verdure in the country near the Rocky Mountains, indicate a deficiency of atmospheric moisture in that region. Snow falls to the greatest depth on the borders of the great lakes. On the sea-coast it is rarely seen farther south than Northfolk, latitude 37°; but in the interior it is found four or five degrees farther south. Compared with the middle countries of Europe, the United States occupying a more southern position, have rains more regular and heavy, and greater in absolute quantity, but a smaller number of wet days. Of the winds, the most remarkable are, 1. A moist and warm south or south-west wind, which is supposed to be a branch of the trade-wind, and is felt all over the Atlantic States as far as the Potowmac, and occasionally in New England. 2. Another wind, possessing the same qualities, and believed also to be a branch of the trade-wind: it blows from the Mexican Gulf, up the course of the Mississippi, and seems to send off subordinate branches, which ascend the courses of the Ohio and Missouri. In Louisiana and Arkansas, it is a south wind; at Council Bluffs, on the Missouri, it is a south-east; and in Ohio and Kentucky, a south-west wind. It is the prevailing wind in all these districts. 3. The north-west blows occasionally on the west side of the Alleghanies, but more frequently on the east side, and is most prevalent in New England. It everywhere produces intense cold, depressing the thermometer to —7° or —8° in Ohio, and sometimes to —20° in Massachusetts. 4. The north-east is a cold wind, which, transporting the fogs of the Newfoundland bank, occasions showers of snow. Various facts observed in the United States seem to show, what some meteorologists have doubted, that clearing and cultivation improve the climate, at least so far as regards the growth of the cerealia.[1]

Geology.

If we draw a line from New York to the east end of Lake Ontario, the peninsula lying north-eastward between the St Lawrence and the sea consists of primitive rocks, interspersed with some patches of secondary. From this line southward the country has a different geological character. A belt of alluvial soil, beginning at Long Island, extends along the shore of all the southern states to Natchez on the Mississippi, having an average breadth of a hundred miles, and probably including all Florida, except some high ground in the interior. It is everywhere penetrated by the tide-water in the rivers. On the west side of this is a region of primitive rocks, from 100 to 200 miles broad, in which gneiss predominates. It embraces the eastern ridges of the Alleghanies, with the rolling country at their foot. On the west side of this, again, is a long narrow zone of transition rocks, including the western ridges of the Alleghanies, and extending from Lake Champlain to the north-west angle of Georgia. From this transition formation, which constitutes, as it were, the eastern edge of the basin of the Mississippi, immense beds of secondary limestone, sandstone, and shale, cover the country to the Rocky Mountains, interrupted only by the alluvial formations on the banks of the rivers, and by the Ozark Mountains. Like the Alleghanies, these mountains present the same formations, disposed in the same order. The Rocky Mountains, so far as they have been explored, consist of primitive rocks, granite, gneiss, quartz rock, &c., covered on the east side by an extensive formation of old red sandstone.[2]

That important mineral, coal, is found on both sides of the Alleghanies. The two principal formations on the east side are, 1. On the river Apomatox, above Richmond in Virginia, where a seam of excellent coal, which occupies a basin twenty miles long and ten broad, has been long worked, and employs 5000 persons: 2. At various spots along a narrow tract of country, from the sources of the Juniata and western Susquehannah to Providence Bay. At Lehigh, and other places within this district, the coal is worked. On the western side of the Alleghanies, an immense formation of coal, probably the largest in the world, extends from the head waters of the Ohio southward to those of the Tombigbee, and westward, with some interruptions, beyond the Mississippi. A similar bed appears on the west side of the Ozarks, which is also traced far up the course of the Missouri; and there is a third bed of unknown extent on the east side of the Rocky Mountains.[3]

Salt, another mineral of primary importance, is distributed in considerable abundance over the United States territory, especially those parts that are remote from the sea. A great formation of rock-salt (and gypsum), indicated by numerous salt springs, is believed to accompany the coal formation over a great part of the basin of the Mississippi. Salt springs are numerous at the foot of the Rocky Mountains, and extensive plains occur covered with salt, one of which, the Grand Saline, is thirty miles in circumference, and in hot weather is covered with a crust of clear white salt from two to six inches deep, and superior in quality to manufactured salt. On the east side of the Alleghanies, salt is generally obtained from the ocean, or imported.

Iron is found in nearly all the states, and is worked to such an extent that, of 50,000 tons consumed, according to computation, in the country, only 10,000 are imported. (Morse, i. 236.) A bed of magnetic iron ore, from eight to twelve feet thick, in gneiss, and another from two to twenty feet, extend, with some interruptions, from the White Mountains on the one side, and from Lake Champlain on the other, to the northern limits of New Jersey. Iron ore, of various kinds, is also found in Maryland and Virginia. On the west side of the Alleghanies it is abundant, and is extensively worked at Pittsburg, and in Kentucky and Tennessee. The whole number of furnaces, forges, and bloomeries, in 1810, was 530. Ores of copper are smelted in New Jersey, and are found in various other parts of the Union. Native copper is said to exist in great quantities near the river St Croix, in the North-West Territory; but at present the United States are chiefly supplied with this metal from Mexico. Lead is found in Massachusetts and Pennsylvania, but it exists most abundantly in Missouri, at the north-east angle of the Ozark Mountains, where forty-five mines are worked, which yield three millions of pounds annually. (Mellish, 366.) Gold is found in considerable abundance in Virginia, between the tide river, and the blue ridge in the Alleghany Mountains. A map has been published exhibiting a condensed view of this interesting region, which has been surveyed and explored; and the gold annually obtained is estimated, "it is stated, in millions of dollars," and it is rapidly increasing, though, comparatively speaking, only the surface of the ground has been disturbed in obtaining this precious metal. Some of the Virginian ores were pounded in a mortar, and the sand being washed away, a large proportion of metallic gold appeared in numerous and beautiful grains, though no ed

es.

gold was visible on the outside. Those who have explored his country are of opinion that it is decidedly rich in minerals; and, from the situation of the mines in a populous istrict, with a complete command of machinery of every escription, there will be great advantages for working them. The gold mines on the Rappahannock are not above half a ozen miles from the city of Washington. The rich gold eins are said to be finely developed; to be composed of uartz, commonly called white flint, from one to five feet thickness, generally perpendicular in the earth, like a wall, upported on both sides by soft talcose slate; and to extend om the surface to an unknown depth. Gold has not unually been found in the broken veins of the fragments at e surface; and it has also been found at the depth of 160 et, increasingly rich.[1] Mercury and tin have not been und. Cobalt, antimony, manganese, and ores of zinc, occur some few spots. Nitre is obtained in vast quantities from e limestone caves in Kentucky. On a general view, it ay be said that the United States have a supply of coal, lt, iron, lead, and probably copper, adequate to their own nsumption.

kes.

The United States have no considerable lake entirely within eir territory, except Michigan. But a series of fresh-water kes, by far the largest in the world (for the Caspian Sea is lt), and connected with one another by the St Lawrence, tends along the northern frontier. The following is their tent, and their elevation above the level of the sea.

Lakes.	Length.	Breadth.	Area.	Height in Feet.
Superior.........	350	150	35,000	642
Huron..........	220	150	17,000	589
Michigan........	310	70	18,000	...
St Clair..........	30	30	900	570
Erie..............	230	55	10,300	560
Ontario..........	170	50	7,200	110
			88,400	

Reckoning from Quebec to the western extremity of Superior, these lakes afford a line of 1550 miles of inland navigation, which will be increased to 4500 miles if we include whole extent of their shores. But Quebec is far from open sea, and the shortest and best route to the Atlantic from Lake Erie and the waters above will be by the w York Canal. Lake Erie is about twenty fathoms in erage depth, Ontario eighty, and Lakes Huron, Michigan, l Superior are said to be still deeper. All these inland ters can be navigated with advantage; and will be owded with vessels at some future period, when an active pulation covers the North-West Territory. The principal erruptions at present are, 1st, at the rapids between ontreal and Kingston, where it is proposed to cut a canal; at the rapids and the great fall of Niagara, where a canal also projected; 3d, in the stream of the river between kes Huron and Erie, where there are also rapids, and in ke St Clair, which is full of shallows; 4th, at the falls St Mary, between Huron and Superior, amounting to enty-three feet in half a mile. All these obstructions, it elieved, can be surmounted by art. These various lakes dently occupy the bottom of a raised plateau, the outer es of which are not very distant; and hence they receive y few rivers of any magnitude. Their shores are beset h ice for two, three, or four months in the year.

Lake George, thirty-six miles long and seven broad, pours waters into Lake Champlain, which is 160 miles long and hteen broad, and communicates by the river Sorelle with St Lawrence. A canal, twenty two miles long, now nearly finished, connects Lake Champlain with the Hudson. We pass over the other lakes of smaller size.

United States.

Rivers.

The rivers of the United States belong to four different systems: 1st, those which water the Atlantic region; 2d, the Mississippi and its branches, which water the great central valley of North America; 3d, those which flow into the St Lawrence; and, 4th, the Columbia and its tributaries, which flow into the Pacific Ocean.

Eastern rivers.

The rivers which fall into the Atlantic and the Gulf of Mexico, from Maine to the eastern boundary of Louisiana, all rise in the Alleghanies, except the Susquehannah and the Hudson, which pass entirely through the principal chains. Their length varies from 200 to 450 miles, increasing gradually with the breadth of the level country, as we advance southward. The tide-water ascends in all these rivers to the outer boundary of the primitive formations, where falls regularly occur, except on the Hudson. In this river the tide reaches to Albany, 160 miles from its mouth, to which point there is an uninterrupted navigation for sloops of eighty tons. This peculiar advantage has made the Hudson the scene of a more active inland trade than any river, perhaps, in the world, of the same magnitude. Tide navigation reaches a very short way up the great rivers in the northern states generally; but in those south of the Susquehannah, it reaches generally from 100 to 130 miles. Boats ply on these rivers much farther up, but the navigation is seldom uninterrupted. The following are the principal rivers on the Atlantic side, with their computed lengths.

	Miles.		Miles.
Connecticut.........	290	Roanoke..............	230
Hudson...............	300	Pedee..................	290
Delaware.............	270	Santee..................	300
Susquehannah.........	350	Savannah..............	280
Potomac...............	260	Catahouche...........	400
James River..........	200	Alabama..............	440

Northern rivers.

The rivers that fall into the St Lawrence and its lakes are comparatively small, and probably do not carry off one tenth part of the water that falls on the east side of the Mississippi. The most considerable are the Fox River, which falls into Lake Michigan, the Miamie of Lake Erie, the Genessee, and Seneca of Lake Ontario, and the Sorelle or Richlieu, which joins the St Lawrence below Montreal.

Mississippi.

The majestic Mississippi drains a greater surface than any river in the world except the Amazon, and in the magnitude of its stream is only surpassed by the Amazon and the Plata. It has been computed to convey to the Mexican Gulf $\frac{1}{38}$th of all the water which the ocean receives from the dry land. The extreme length of the Mississippi proper, including all its sinuosities, is generally computed to be 2500 miles, but reckoning to the head of the Missouri, which is the largest branch, it is nearly 4000. It has three bars at its mouth, the deepest of which affords only seventeen feet of water. (Warden, i. 114.) Sloops of this draught can navigate to Natchez, 350 miles from its mouth. There is depth sufficient at all times for sloops drawing six feet to the Ohio, and for vessels drawing three feet to the junction with the Missouri. (James's Expedition, iii. 258.) But during the floods in May, June, and July, the waters rise fifty feet, and are then navigable by vessels of any size. The Mississippi, from its junction with the Ohio to the sea, is about 1000 yards, or two thirds of a mile, in width, and below Red River it is about 120 feet deep. From the junction of the Arkansas, its banks form an elevated ridge or platform, which support the stream at the height of ten or twenty feet above the level of the adjacent lands. In its floods, it sometimes bursts the barriers which confine it, and inundates the flat country below. Of the two great branches, the Missouri, and Mississippi proper, the former stream is the larger and more rapid, and also more turbid, from the quantity of travelled soil it transports;

---

[1] See American Railroad Journal, p. 437.

but its waters, generally occupying a wider channel, are more loaded with bars and sand-banks, and the navigation is more intricate. (James's Expedition, iii. 259.) The Platte, Kansas, and some other tributaries of the Missouri, often extend to a breadth of one or two miles, and during the warm season dry up entirely. But these, and all the branches of both rivers, generally admit of boat navigation for nine tenths of their course, during a longer or shorter period every year. In the Ohio, the boating season is from 20th February to the middle of June. Before this period the waters are ice-bound; after it they are too shallow except for very small craft. The length of the Mississippi, from its mouth to the junction of the Ohio, is about 1200 miles, and to its junction with the Missouri, 1300. The length of the Missouri, above the junction to its remotest branch, is, by Lewis and Clarke's measurement, 2575 miles. The length of the Ohio, above the point of confluence, is 1188 miles. The other large branches of the Mississippi are the Red River and Arkansas, in the lower part of its course. The chief tributaries of the Missouri are the Osage, Platte, Kansas, and Yellowstone; of the Ohio, the Tennessee, Cumberland, and Wabash. The whole extent of the navigable waters above the confluence of the Missouri and Mississippi has been estimated at 23,000 miles, to which, if we add 12,000 for the Ohio, Arkansas, Red River, &c., and their branches, we shall have 35,000 miles of boat navigation in the basin of the Mississippi. To this we may add 10,000 miles more for the eastern section of the states, with 5000 for the lakes and their tributary streams, and 2000 for the river Columbia, making altogether 51,000 miles of river navigation, which is probably three times greater than all the rivers of Europe afford. Except in New England, Pennsylvania, and New York, the rivers of the United States flow over a surface which has rather a small declivity. Of the two sides of the great central valley, the western is the steepest. The base of the Rocky Mountains is computed to have an elevation of 3000 feet. That of the beds of the rivers, where they begin to be navigable, may be about 2000; and estimating their average length of course to the sea to be about 2500 miles, the mean fall will be about nine or ten inches per mile. The Mississippi proper, at 2500 miles from the sea, has a height of 1330 feet, or a mean fall of six or seven inches per mile. The Ohio, at Pittsburg, 2200 miles from the sea, has a height of 600 feet, or a mean fall of four inches. In the Amazon and the Ganges, from the point where they leave the mountains, and in the Wolga from its source, the average rate of descent is from four to five inches per mile. In the middle and south of Europe generally, the fall of the rivers is probably twice as great.[1]

Cultivated plants.

The variety of cultivated plants in North America corresponds to the diversity of its climates. At one extremity, the sugar-cane of the tropical regions thrives; and at the other, oats and barley, the staple crops of the arctic regions, are leading articles of cultivation. The high summer heat, however, in all parts of the United States, makes some plants which cannot be raised in England succeed in the coldest districts of the north. Of this description is maize, or Indian corn, an indigenous American plant, which is cultivated from Maine to Louisiana. It is a vegetable in universal use in the United States, yields generally double the produce of wheat, and is adapted to a variety of situations. The maple tree, which grows in all the states, yields a juice from which sugar is made. Nearly ten millions of pounds of maple sugar were made in 1810. Wheat is raised from one extremity of the Union to the other, but succeeds best in the middle and western states, and in the uplands of the southern. The cultivation of tobacco begins in Maryland, about the parallel of 39° or 40°, and continues through all the southern states, and through those in the west, south of the Ohio. The climate favourable for cotton is not found farther north than about the latitude of 37°, though it can be raised as far north as 39° on both sides of the mountains. The best grows in South Carolina and Georgia, in dry situations, upon the sea-coast. The rice crops, which require a marshy soil and a great heat, commence about the same parallel with cotton, and have nearly the same geographical range. The sugar-cane grows in low and warm situations, as high as the latitude of 33°, but the climate favourable for its cultivation does not extend beyond 31½°. Oats, barley, hemp, and flax, succeed well, except in the low grounds of the southern states. The vine can be advantageously raised as far north as Pennsylvania. The olive, orange, lemon, and fig, are injured by the frost in South Carolina; but it is believed that these trees, as well as the banana, will succeed in Florida.[2] The forest trees of the United States comprise almost all the valuable and useful species of wood.

The United States contain about one fourth of the known species of quadrupeds. Some are common to both continents, others are peculiar to the western. Comparing individuals of the same species, some are perfectly similar; between others there is some difference in size, colour, or other circumstances. In a few instances, the animal of the eastern continent is larger than the American; in most, the reverse is the case. The following is a catalogue of the quadrupeds of the United States: Mammoth (an extinct species), bison or buffalo, moose-deer, caribou, red deer, fallow deer, roe, bear, wolverene, wolf, fox, catamount, spotted tiger, sallow cougar, gray cougar, mountain cat, lynx, kincagou, weasel, ermine, marten, mink, otter, fisher, skunk, opossum, wood-chuck, urchin, hare, racoon, fox squirrel, gray squirrel, red squirrel, flying squirrel, field-mouse, field-bat, ground mouse, wood cat, American rat, shrew mouse, purple mole, black mole, water rat, beaver, musquash, morse, seal, manati, sapajou, sagoin.

Nine tenths of these animals yield a fur, which is used for dress or in manufactures. The bison, or wild ox (improperly called the buffalo), is, according to some American naturalists, of the same species with the common neat cattle of the United States, the difference being the effect of the domestication of the latter. Buffon, however, thinks otherwise. The bison is larger than the domestic ox, has a fleshy or grisly substance extending along his shoulders and back, and has on his neck and shoulders a woolly hair, which admits of being spun or wrought into hats. The moose-deer, now rare, is a gigantic animal, one variety sometimes reaching the height of twelve feet. The caribou is probably the rein deer of Scandinavia. The bear is of two species. The short-legged lives chiefly on vegetable food, and is probably not carnivorous. He dozes away the winter in a torpid state, sucking his paws, and expending the fat he had previously acquired. The ranging bear is larger, but more lean. He destroys calves, sheep, pigs, and sometimes children, and in winter migrates southward. The wolf, like the bear, is found in all the states. It is a voracious animal, stealing into sheep-folds at night, attacking deer, hogs, and small cattle, and sometimes hunting in packs. The catamount is of the size of a large dog, and extremely ferocious, but it is rarely seen. The spotted tiger is scarcely seen, except near Louisiana. It is from five to six feet long. The cougar or American panther is about the same size, but more common. It destroys sheep, calves, and hogs, and when hungry will attack large cattle. The urchin differs in several respects from the European hedgehog. The lion, leopard, striped or true tiger, hyena, elephant, rhinoceros, hippopotamus, camelopard, are unknown in the New World. The horse, the ass, the sheep, the goat, the og, and the camel, did not originally exist there, but have een naturalized. The latter, however, are not numerous, nd have never been introduced into the United States. f the birds and reptiles our limits will not allow us to eak in detail. The eagle, pheasant, grouse, partridge, van, Canadian goose, ptarmigan, are less or more numer- ıs. In general, the small birds of America surpass those Europe in the beauty of their plumage, but are much ferior to them in the melody of their notes. Among the ptiles, the most remarkable is the alligator or American ocodile, from twelve to twenty-three feet long, very strong d active. Of serpents, the rattlesnake, from four to six et long, is the most formidable.[1]

[1] Warden, i. 115. Mellish, 32. Major Long's Memoir, in James's Expedition, with the Sectional Maps.

[2] Warden's Introduction, 27; ii. 399; iii. 222. Humboldt, proleg. 156.

Perhaps no single circumstance connected with the nited States has attracted so much attention as the rapid owth of their population. Philosophers had shown, from e laws which govern propagation, that the human species ight double its numbers in a short period. But this was ly known as a speculative truth, applicable, it was sup- sed, to small tribes under extraordinary circumstances, t not to a great nation of many millions. The Spanish lonies, planted a hundred years earlier than the United ates, should have made this principle familiar to the world ng ago; but ignorance and misgovernment, intercepting e bounty of nature, inflicted all the vices and evils of old cieties upon these colonies, and a jealous policy threw a il of secrecy over their condition.

The first European emigrants settled in the United States 1607. From that period, colonists continued to flock to e country in small parties or large bodies. The last new settlement on a considerable scale was in 1733, when, by means of a grant of L.10,000 from parliament, and various sums raised by private contributions, 618 persons were sent out from England to Georgia.[2] The growth of the colonies was rapid and obvious; but much more was probably attributed to the influx of settlers from the mother country than was consistent with the truth. No accurate enumeration of the inhabitants was made till the first census was taken in 1790. That for the year 1753, in Marshall's Life of Washington, is undoubtedly erroneous. The ratio of increase being ascertained by the four separate enumerations, and having continued remarkably uniform for forty years, we can now, by calculating backwards, obtain results more deserving of confidence than the rude guesses made from uncertain data. The period of doubling at present is $24\frac{1}{6}$ years; but, taking it at 25 years, and reckoning backwards from 1790, we find the population at the under-mentioned periods would be,

1790	3,929,000 (by census)	1715	490,000
		1690	245,000
1765	1,960,000	1665	122,000
1740	980,000	1640	61,000

Beyond the last-mentioned period we cannot, for obvious reasons, carry our calculation. If we suppose 1000 settlers to have come from Europe annually for the first thirty-three years, these, by natural multiplication, would amount to about 60,000 at the time alluded to, that is, in 1640. The following table, constructed from authentic documents, gives an interesting view of the progressive advances of population in the different states.

States and Territories.	1790.	1800.	1810.	1820.	1830.	Square Miles.	Population in each Square Mile.	Senators.	Representatives for 1830.

[1] Morse, vol. i. p. 263, &c. Warden, chap. vi. Buffon's Quadrupeds. vol. ii. London, edit. 1775.

or an account of this and the earlier settlements, the reader may consult the History of the British Empire in America. Lond. 1741, 2 vols. 8vo.

United States.

The following is a later census of several states and territories:

Maine.........	1837,	485,451	Illinois.........	1835,	272,427
Massachusetts.	1837,	701,331	Michigan......	1837,	174.169
New York.....	1835,	2,174,517	Florida.........	1838,	48,223
Georgia.........	1838,	661,702	Wisconsin.....	1838,	18,149
Mississippi....	1837,	308,744	Iowa............	1838,	21,796
Arkansas......	1838,	69,710			

According to the census which is now in progress, and is nearly completed, the population, it is estimated, will nearly amount to 17,000,000.

It will be observed from the first table, that the rate of increase is very unequal for the different sections of the Union. The older states of Connecticut and Massachusetts have only added one fifth to their population, in the same period in which the new states of Kentucky and Ohio have quadrupled theirs; and, according to the more recent census of 1830, the increase of population has been in like manner far more rapid in the newly-settled states of Indiana, Illinois, Missouri, Arkansas, and Michigan, where it has more than doubled within ten years, than in any of the northern and first-settled states, in which the increase has only been from five to forty, fifty, and sixty-one per cent. Even in Kentucky and Ohio, where the population increased so rapidly the first thirty years after they were settled, it has now been checked by those causes which never fail to operate in all countries with the increase of inhabitants and the occupation of the land; which have been long felt in the crowded communities of Europe, as they are now in all the older states of America. There is still another reason for the comparatively rapid increase of the newly-settled states of the west, namely, that the more densely-peopled parts of the Union, and in particular New England, serve as a nursery to the new states, to which they are continually sending out large draughts of emigrants. Thus there is a constant stream of population pouring across the Alleghanies, from the east side to the west, to occupy the vast plain of the Mississippi; and by this gradual generation of a mighty people from a central stock, a uniformity of language, manners, and institutions, is diffused over the whole, which will cement their union, in spite of local diversities of interest, and which promises to make the countless millions who will by and by cover North America from sea to sea, more truly *one people* than the inhabitants of Austria, Prussia, France, Spain, or Britain, are at this day.

If we calculate prospectively from the present rate of increase, assuming that it will continue permanent for some time, the population at the under-mentioned periods will be,

1845	20,000,000	1895	80,000,000
1870	40,000,000	1920	160,000,000

Before this last result is realized, some retardation will probably take place in the rate of increase. But even if the vast population alluded to were in existence, the average density for the whole territory would not be greater than it is at this day in Massachusetts, and only half as great as in Italy, France, and the British Isles.

The rapid growth of the population in America becomes much more striking when we contrast it with the scarcely perceptible progress of communities in the Old World. France, which, according to Marshal Vauban, had 19,094,000 inhabitants in 1700, had 26,363,000 in 1791. Now, according to the rate of increase which this indicates, that country would have doubled its population in 195 years; but the population of the United States in the same period would have increased to 220 times its first amount. The following table, calculated from the best data to be obtained, shows the comparative rate of increase in different countries.

	Annual Increase on each 10,000 Persons.	Period of Doubling.
United States (according to census of 1810 and 1820),	291	24$\frac{1}{6}$ years
France, from 1700 to 1791,	34	195
Ditto —— 1791 to 1821,	48	144
England —— 1801 to 1821,	137	51
Europe for the last 30 years,	76	90

From 1820 to 1830, the increase on each 10,000 of the American inhabitants amounts to about 3000.

The following table contains a census of the slave population, according to five enumerations.

* Not slaves, but "indented colored servants."

The existence of slavery is the standing reproach of America. In the structure of society, it is a flaw which as corrupted the manners of the people and the policy of e state. In the northern provinces, the people are sen- ble of its evils, and of its peculiar reproach in a land f freedom; and they have not failed to convey these entiments to the proprietors of slaves. Slavery has ac- ordingly been abolished, and is nearly extinguished, in all e New England states and in New York, and is hasten- g to its extinction in Pennsylvania, New Jersey, Dela- are, and Maryland. By the laws of Pennsylvania, all rsons born within that state since 1780 are free, the ildren of a slave being subject to a limited servitude to r owner. .In New Jersey, every child born after July 04 is declared free, and all traffic in slaves was prohibited 1798. The revised laws of New York declare, that every rson born in that state is free; that all persons brought to the state, except for a limited period, become free; and at no person can be sold within the limits of the state. The dinance for the territory north-west of the river Ohio, ssed in 1787, prohibits for ever the introduction of sla- ry into that tract of country in which the four states of diana, Illinois, Missouri, and Michigan, have already been rmed. The introduction of slaves from abroad was pro- bited by Virginia in 1798, and by Congress into the ississippi territory in the same year; and in 1808, by the me authority, into any part of the United States. But ough declining, slavery still prevails in the southern states, mely, Kentucky, Tennessee, Virginia, the Carolinas, Geor- , Louisiana, Alabama, Mississippi, and even in the dis- ct of Columbia, and is the fruitful source of complicated ils. Louisiana and several other states prohibited the intro- ction of slaves from any other state except by an immigrant oprietor; but an active internal trade among the south- states is carried on in slaves, who are exported in great mbers from the worn-out districts towards the north and st, to be employed in the cultivation of new and fresh tton lands in the south. Like the lower animals, slaves encouraged to breed and to multiply, by those who have ested their capital in the trade.

But slavery, if it be the reproach of America, the far- ned land of liberality and freedom, is also her misfortune; d the slave-holders would receive, as they would merit, sympathy and aid of Europe, if they would endeavour improve the condition of the slaves, and gradually pare them for emancipation, the only consummation which it is so devoutly to be wished that slavery, unhappily begun, should happily end. In a commu- y divided, as in all slave-holding states, between two stile races,—the oppressor and the oppressed,—there two alternatives, either by kindness and humanity mingle the two into one, or to maintain by rigour the dage and degradation of the inferior cast. In the one e, the slaves are retained in chains and darkness, without e, and the system will only stand so long as power re- ins on the side of the oppressor. But so surely as love ings from kindness, resentment, curses not loud but deep, the fruits of oppression; and thus, in a long course abused power, a standing feud is established between great sections of the community, an arrear of ven- nce accumulates, which, if occasion offers, will be duly aid by the oppressed class, in a measureless retribution, ages of violent wrong; and how precarious therefore st be the condition of society, where one class lives in tinual dread of the other, the sentinel ever at his st, and where the slumbering vengeance of thousands y at any moment awaken into activity, and convert whole country into one scene of anarchy and blood. was from this just apprehension, and from a desire to e out the moral stain of slavery, that Great Britain, a generous policy, emancipated the slaves in her West dia colonies; and though the proportion of blacks to whites was much greater, being ten, and sometimes twenty, to one, than in North America, where they seldom amount to above a third of the population, yet their emancipation would be a great reform, which would conduce not less to the improvement of morals than to the peace of society. But this great change must be the work of time. The way must be prepared by the diffusion of intelligence and of purer morals; and great was the error of those over-zealous missionaries who went about preaching to the American slaves the dangerous doctrine of natural right; thus agitating society by the fear of some dreadful crisis, which might involve the land in devastation and blood, or, if authority were maintained, which would rivet, and render more cruel, the yoke of slavery. And such, in point of fact, has been its effect. The incendiary doctrines of these apostles of freedom really alarmed the slave-holders for their lives and properties; and they now regarded them as the enemies of good order, to be repressed and punished, and treated some of them so roughly that they narrowly escaped with their lives. It is clear that slavery will never be abolished, either in America or elsewhere, except by the aid of the slave-holders themselves. In the West India islands they were gained over by a bribe of 20 millions sterling; and it is only, we fear, by some such powerful argument that the master will ever consent to the emancipation of the slave. There is no authority in America that could effect the abolition of slavery. An act of Congress for this purpose could scarcely be obtained; and it is even doubtful how far the wealthy planters of the south would submit to a law passed, as they would reason, by fanatical zealots, and endangering both their property and their lives. Such discussions are now considered to be dangerous and inexpedient. Hence they are forborne in the Congress, and still more all attempts to legislate on the subject, as putting in jeopardy the supreme authority and unity of the empire.

The alarm excited in the southern states, by the missionaries of freedom, has rather been unfavourable to the slaves. Fear has, as usual, been the parent of cruelty. It has added to the rigour of their bondage, and has given rise to laws without a parallel for barbarity in any civilized country, which are intended for ever to debar the slave from the blessings either of knowledge or of religion. In all the slave-states, namely, the Carolinas, Virginia, Georgia, Louisiana, &c., not only are those cruel laws enforced against slaves, but, in the wantonness of abused power, they are extended to free men of colour, who are exposed to every species of injury and insult. They are not allowed to pass from one state into another. Mr Stuart, who cannot be accused of prejudice against American manners or institutions, relates of an individual in South Carolina, who was accustomed, during the unhealthy season, to go from Charleston to New York, that, by a law recently passed, he was prohibited from crossing the boundary, under the pain of not being allowed to return; and thus, having his wife and children in the state, he was confined a prisoner within its limits; while a person of colour coming into the same state, or brought in by a vessel, is apprehended and confined in jail until the vessel is ready to sail. It is contrary to law that this class of nominal freemen, but real slaves, shall be educated; they are not competent witnesses where the rights of the other class are concerned, though their testimony is received against each other, as is even the evidence of slaves; and they are tried for any offence with which they may be charged, by a justice of the peace and freeholders, without the benefit of a jury. From those laws passed against the offspring of slaves having the original taint of slavery, we may infer the treatment of the slaves themselves. Several barbarous enactments have lately been passed. In 1830 the state legislature of Louisiana ordained, that " whosoever shall write, print, publish, or distribute any thing *having a tendency* to create discontent among the free coloured population of this state, or insubordination among the slaves, shall, at the discretion of the court, *suffer death, or imprisonment at hard labour for life.*" The same language used in any public discourse from the bar, the bench, the stage, the pulpit, or in any place, or in private conversation, or the bringing into the state any paper, pamphlet, or book, having any such tendency, shall subject the offender to not less than three years and not more than twenty years hard labour, or death. The teaching of a slave, or permitting or causing to be taught, any slave, to read or write, is declared punishable with imprisonment for not less than one and not more than twelve months. Another act provides for the expulsion from the state of all free people of colour who came into it subsequent to the year 1807; it prohibits any of this class from entering the state, and sentences to imprisonment or hard labour for life such as disobey the order for their departure. These laws present a revolting picture of degradation and suffering on the one hand, and of disquiet and terror on the other. The ruling class live in daily terror of vengeance from their wretched slaves, and hence these cruel precautions. Their cruelty brings its punishment along with it; it is the measure of their misery; and therefore in relaxing the bonds of slavery, the happiness of all parties would be promoted.

In Europe, many cruel and unjust laws have been passed, which have fallen into disuse with the progress of society. But in the slave-holding states of America, congenial manners give force to tyrannical laws. With some exceptions, the general treatment of slaves is harsh and cruel; a fact to which all travellers in the southern states of the Union bear ample testimony. Mr Stuart, already mentioned, and the duke of Saxe-Weimar, in describing the treatment of American slaves, give the particulars of the grossest cruelty, by individuals who are in the habit of beating and ill-using their slaves on the slightest offence, or sending them to gaol, where the slave, on the payment of a fee to the gaoler, is, without further inquiry, fastened to a machine and lashed without mercy. "Nothing is more common," says Mr Stuart, "than for the masters and mistresses of slaves, either male or female, when they wish them to be punished, to send them to a prison, with a note to the gaoler, specifying the number of lashes to be inflicted. If the master so orders it, the slave receives his whipping laid flat upon his face upon the earth, with his hands and feet bound to posts. In passing the prison in the morning, the cries of the poor creatures are dreadful."[1] At the public sales of slaves, where the ties of nature are rudely torn asunder, scenes occur which are revolting to humanity, and which, without the aid of laws, would be utterly repudiated by the improved manners of Europe. Where these maxims prevail, they forbid all hope of alleviating the lot of the slave; and the great point would therefore be, to impress on the slave-holders themselves, not only the cruelty, but the error of their measures. They are no doubt obstinate and prejudiced; but in time the voice of reason may prevail so far as to lead to a mitigation of the present harsh code, and pave the way for the abolition of slavery throughout the country.

In the southern states of the Union, namely, the Carolinas, Virginia, Georgia, Kentucky, Alabama, Mississippi, Tennessee, Arkansas, slavery appears to have fixed its permanent abode; and, according to the following table, which exhibits the progressive increase of the two different races for the last forty years, there has not been so rapid an increase in the white as in the black population.

Increase on each 100 *of the Whites and the Blacks in North Carolina.*

	Slaves.	Whites.

In France and England, and probably in Europe at large, the females exceed the males by two or three per cent.; but in the United States generally, the males exceed the females by nearly four per cent. In the newest states, the excess is as high as nineteen per cent. (Seybert, p. 42.) The difference is still more striking in what relates to ages. In the United States, children form a much greater, and aged persons a much smaller, proportion of the population than in Europe. In Sweden, according to Wargentin's Tables, the persons under the age of sixteen form thirty-six per cent. of the population; in Britain, according to the last census, forty; and in the United States fifty per cent. The persons aged above forty-five form twenty-two per cent. of the whole population in Sweden, eighteen per cent. in Britain, and twelve per cent. in the United States. This peculiarity arises from the rapidly progressive state of the population. Since the inhabitants of the United States quadruple their numbers in fifty years, a person born half a century ago belongs by his birth to a society of two millions and a half of persons, but now lives in a society of ten millions, which will furnish four times as many old men to a future and equidistant period. The annual amount of immigration (to borrow an American word) is very variable, and its effects have been greatly overrated. The whole number of passengers who arrived in 1817, at the ten principal ports, was 22,240, including citizens, and persons on business who did not mean to remain in the country. In 1816, it was estimated at 20,000; in 1818 and 1819, at 28,000 each, not more than one half of whom, very probably, were strangers ed es.

---

[1] Stuart's Three Years in America, vol. ii. p. 206.

ome to settle. In 1820, the true number of immigrants, ccording to the National Calendar, was 7001, of whom 042 were males, consisting of 997 agricultural persons, 461 commercial, 1407 manufacturers, artisans, &c. Dr eybert thinks the average number of foreigners who come) settle in the United States does not exceed 6000 per nnum; but assuming it to be 8000 or 9000, this is only om $\frac{1}{30}$ to $\frac{1}{35}$ of the whole annual increment, which must mount to 290,000 persons to make the population double 1 $24\frac{1}{6}$ years.[1]

ality.

This rapid increase does not greatly affect the rate of the nnual mortality, which is proportionally rather greater nong the persons under twenty-five than among those of l ages. In the absence of proper data for ascertaining the nnual mortality of the whole country, or of any particular ate, we can only refer to a single fact. The average umber of deaths in Philadelphia, for eight years (1807 to 314), was found to be about $\frac{1}{43}$ of the contemporaneous opulation. (Seybert, p. 50.) In Birmingham, in the ten ears ending 1811, it was about $\frac{1}{30}$, in London $\frac{1}{34}$, and in l England, including the army and navy, about $\frac{1}{44}$ or $\frac{1}{45}$. Milne's Annuities, p. 456.) This single fact, therefore, as r as it goes, bears testimony to the salubrity of the climate, ıd to the comfortable condition of the inhabitants, of the nited States.

s.

The active population in the United States is proportionally greater, and the idle population less, than in any her country. They have few public functionaries, reachers, or annuitants, and a very small army and navy. ccording to a table which will afterwards be inserted, the ctive population amounts to twenty-seven per cent. of e whole, or two per cent. more than the number of males bove the age of sixteen. The proportions employed in griculture, manufactures, and commerce, according to the ensus of 1820, were,

Agriculture	83·7 per cent.
Manufactures	13·5
Commerce	2·8
	100·0

But the number assigned to commerce evidently does ot include mariners, or includes only those who resided ı shore at the time the census was taken. For the sake comparison, we give the general result of the British rerns for 1811, remarking however that the two classifitions are not constructed on the same plan, the second ead in our arrangement corresponding to the second and ird in the American.

Agriculture (by families)	$35\frac{1}{3}$ per cent.
Trade, manufactures, and handicraft (ditto)	$44\frac{1}{3}$
Other persons (the unproductive class, military, placemen, clergy, &c.)	$20\frac{1}{3}$
	100

s and rism.

The situation of the labouring classes in the United tates is confessedly far superior to that of the same deription of persons in any other part of the world. Wages e so high, compared with the price of provisions, that an merican labourer, who should live exactly as labourers ve in other countries, might always save the half of his rnings. The average wages of a labourer were estimatl at seventy-five cents a day by Mr Blodget, and more cently at eighty cents by Mr Niles, wheat being one and half dollar per bushel. (Warden, Introduction.) In such rcumstances, a very moderate degree of industry suffices to place a man above want, and pauperism can only be the lot of those who are debilitated by old age or disease. Accordingly, it is a proud distinction for North America, that this moral deformity, except so far as it is the consequence of natural and unavoidable misfortunes, is almost unknown within her borders. It is not there as in the old countries of Europe, where a person who is able to provide comfortably for his own wants, has still his feelings exposed to daily laceration from the sight of multitudes of miserable beings, who exhibit human nature in its most loathsome and degraded state, and whose wretchedness it is beyond his power to relieve. It is Rochefoucault, we think, who remarks that he had seen only one beggar in the United States. Mendicity does exist; but except in the large cities, where foreigners are often found in a state of destitution, it rarely obtrudes itself on the eye, and may be said generally to be as rare in that country as it is abundant everywhere else. In Europe, the paupers have been supposed, on a rough calculation, to amount to one-twentieth part of the population. In the United States, they were estimated by Mr Niles, some years ago, at one person in 250 on the Atlantic coast, and one in 350 in the interior. But in times of great public calamity, the proportion is much higher. In the New England states, and in some of the others, though not the whole, each parish is obliged to provide for the support of its own poor, according to the humane spirit of the English laws. (Morse, vol. i. p. 293. Warden, *passim*.)

United States.

States.

The North American Union comprehends at present twenty-six distinct states, each governed by its own constitution; three territories, in which civil governments are established without constitutions, namely, Florida, Wisconsin, and Iowa, the two latter having been erected into territorial governments in 1836 and 1838;[2] and other three territories, which are yet unoccupied by a civilized population. To these we must add the district of Columbia, comprising a space of ten miles square round Washington, and placed under the exclusive authority of the federal government.

The thirteen original states which concurred in the declaration of independence on the 4th July 1776, were New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia, North Carolina, South Carolina, Georgia. Vermont was then an appendage to New York, and Maine to Massachusetts. The extent of the several states is very unequal. Rhode-Island and Delaware are specks in the map, rather smaller than Devonshire or Perthshire. New York, Pennsylvania, and the new states generally, are each larger than Ireland or Scotland; while Virginia, Georgia, Missouri, and Illinois, severally exceed England in extent. The density of the population diminishes pretty regularly in every direction as we recede from Massachusetts; and in that state, where it is greatest, it rather exceeds that of Spain or Poland, or Europe taken altogether. The mean density for all the states east of the Mississippi, including the district of Columbia, and also the state of Louisiana, is nearly forty-one persons to the square mile.

State governments.

Some writers, who derive their political ideas from the old institutions of Europe, strongly disapprove of the division into states, with distinct local governments. But this arrangement, though originally the effect of accident, is admirably adapted to the circumstances of the country, and deserves to rank as an improvement in the science of legislation. It is the only system by which the great advantages of union could be combined, in such a gigantic empire, with a due attention to the separate interests of all the parts. The federal compact, by preserving peace and friendship among states that would otherwise be rivals and enemies, exempts them from the scourge of frequent wars, gives unbounded freedom to their internal trade, and, while it enables them to dispense with that sort of strong government which is scarcely compatible with liberty, it gives them an aggregate strength, which secures them against external attacks. On the other hand, each separate district, acting by its own legislature, is invested with the entire regulation of its local concerns, which can never be intrusted to others without the certainty of mismanagement. No single legislative body, even were its sessions perpetual, could properly conduct the local business of such an empire as that now forming in North America. In our own parliament, it is notorious, that, from the multiplicity of business transacted, the general style of legislation is most slovenly, and bills of all kinds, but especially local bills, are often grossly mismanaged. How great an impediment is it felt to be to the redress of grievances, or the promotion of improvements, in the remote parts of Scotland and Ireland, that witnesses, parties, and agents, must be carried six or seven hundred miles, at a vast expense, and that, when they reach the seat of legislation, every thing must depend on the votes of persons who either understand their business imperfectly or not at all, and who are only prevailed upon, by solicitation, to bestow a slight attention upon it. The division into states supplies the only remedy to this great evil. It encourages local improvements, by uniting those whose situation gives them a community of interest as to certain objects. It lessens corruption in the general government, by subdividing patronage. In times of public phrensy, it multiplies the securities against the persecution of individuals, because such persons will always find protectors in some one of the state governments. It has indeed one disadvantage; the state legislatures may become the strongholds of faction, as was exemplified in Massachusetts during the last war. But as the number of states increases, the weight of each in the confederacy, and its power to disturb the union, are diminished. Even out of this danger a security arises against another. The existence of the separate state governments forms a strong barrier against despotism, because it creates so many distinct centres of power, from which resistance might be made, if a military tyrant should master the general government, as Cromwell mastered that of Britain, and Bonaparte that of France. Some inconvenience, no doubt, arises from the unavoidable diversity of laws in such an aggregation of republics; but the evil is not much felt or complained of practically, and it is the necessary concomitant of a union producing boundless advantages. An iron despotism may subject all its slaves to the same laws, without regard to the distinctions of climate, character, or situation; but freemen will not associate voluntarily on such a principle. Liberty consists not in being governed by the laws that are absolutely best, but by those which are deemed best by the people who obey them. No wise and liberal statesman will hold it necessary that the fishermen of Massachusetts, the husbandmen of Pennsylvania, and the sugar-planters of Louisiana, should live under one perfectly uniform system of jurisprudence. Such a uniformity could not be enforced without rending asunder the union. And let it be recollected, that the diversity of laws, such as it exists, is much less than it would be if the federal compact were dissolved, and the several states entirely independent. In short, if it is possible by any device to reconcile freedom with extensive empire; to unite all the parts of a vast continent together in the bonds of peace and commercial intercourse; and yet not to trench materially on the natural rights of each part, or the free use of its natural powers and advantages; it must be by a federative system similar in its essential characters to that of the United States. The experiment is by far the most interesting that has ever been made in the science of legislation; and the steadiness and success with which it has hitherto proceeded opens up the most encouraging prospects as to the future destiny of mankind.

[1] Seybert, p. 28. Carey's Essay on Political Economy, 1822, p. 453, 467. Niles's Register.

[2] A territory becomes a state when its inhabitants, amounting to not less than 60,000 persons, have met and formed a constitution. reviously to this, they are placed under the civil authority of a governor appointed by the president and Congress.

The federal government, of which we shall afterwards speak, possesses merely those specific powers which are vested in it by the constitution. All other powers and rights remain with the state governments, in which the sovereignty essentially resides. The territory of each state is not the territory of the Union, but of that particular state. The people and militia are the people and militia of the several states, not of the Union. Lands are held under the laws of the states; descents, contracts, and all the concerns of private property, the administration of justice, and the whole criminal code, except in the case of breaches of the laws of the federal body, are regulated by state laws.[1] All the twenty-six states have written constitutions, formed subsequently to the Revolution, except Rhode Island, which is still governed by the charter granted by Charles II. in 1663. These constitutions are purely republican, though the right of suffrage (for the term *franchise* is inapplicable and odious where voting is a general right, not a special privilege) is restricted in one or two states, and unequally divided in one or two others. In every one of the states, the legislature consists of two chambers, both chosen by direct popular election, except in Maryland, where the senators are chosen by delegates. In eighteen states out of the twenty-six, the representatives (or members of the lower house, according to our phraseology) are elected annually, and in Tennessee and Louisiana biennially, and in three triennially, viz. in South Carolina, Illinois, and Missouri. The period of service in the senates (or upper houses) varies from one to four years, except in Maryland, where it is five: in some cases one third or one fourth, in others one half, of the members are renewed every year; in others, one half every two years. In some of the states the right of suffrage was formerly limited to freeholders or corporations, but by amendments in most of the old constitutions these restrictions have been abolished; and the right of suffrage, though variously defined in the different states, is substantially universal in them all, except in New Jersey and Virginia. In these two states, the possession of a small amount of property still constitutes the citizen's title to vote. In many of the states, there are certain qualifications prescribed for the persons elected. A senator must, in general, be a freeholder, and not under thirty years of age; a representative not under twenty-five. The governors act in some cases with, in others without a council, and hold their offices, some for one year, some for two, some for three, but none for more than four years. In all the constitutions recently framed, an express provision is introduced for adopting amendments. The rule generally is, that if any alteration is judged necessary and approved of by two successive legislatures, it may then be submitted to the people, who appoint a special convention to decide upon it. In some cases it is provided that a convention shall meet periodically to revise the constitution. The existing legislature is always considered as exercising a trust, in the terms of which it has no power to make the smallest change. By this principle, legislation is founded on a clear and rational basis. It gives stability to institutions that might otherwise be the foot-ball of domineering factions; it checks the growth of sinister interests, and, while it affords a safe and easy remedy for grievances, it is so far from being an inlet to rash innovations, that it is the best guarantee against them, as the history of the United States demonstrates. To suffer those who exercise the supreme power of a country to change at pleasure the conditions by which hey hold it, is as absurd as to suffer the judge to make he laws which he administers, or the steward to fix the erms of the engagement which invests him with the ma- agement of an estate. Under such a system, the steward navoidably becomes a peculator, the judge a tyrant, and the gislature a junto of conspirators against the public weal.

---

[1] Views of the President of the United States on the subject of Internal Improvements, laid before Congress 4th May 1822.

The agriculture of the United States varies according the climate, soil, and situation, of the several divisions the country; but, taken altogether, it differs materially om that of Britain, in the nature of the productions cul- vated, in the condition of those who are engaged in it, d in the general principles by which it is conducted. esides our staple productions, wheat, barley, oats, pease, eans, turnips, and potatoes, the soil of the United States elds rice, Indian corn, indigo, cotton, sugar, tobacco, the ne; and Florida will probably add to these the olive and e banana, which scarcely succeed in the other states. he staple produce of New England is Indian corn; that the middle states wheat and tobacco; that of the south- n, cotton, rice, and, to a limited extent, sugar. Dr Morse dicates the proportional quantity of each species of produce ised, by naming them in the following order, the greatest ing first. In New England, Indian corn, grass, rye, oats, x, wheat, buck-wheat, barley, and hemp; in the middle ates, wheat, Indian corn, tobacco, grass, oats, buck-wheat, x, barley, potatoes, spelts, rye; in the southern states, tton, wheat, tobacco, Indian corn, rice, indigo (formerly), rley, and hemp. The western states, along the Ohio, rrespond in their productions to the middle states on the lantic. Good soils, carefully cultivated, in the United ates, yield 100 bushels of Indian corn or 50 of wheat r acre. But the average produce of the cultivated land Ohio and Kentucky, districts not inferior in soil to any the Union, is estimated as follows: Maize 40 bushels r acre, wheat 22, rye 26, oats 35, barley 30, tobacco 12 15 cwt., cotton 5 to 7 cwt. in the seed, or from 150 to 0 pounds cleaned. (James, vol. iii. p. 199.) This great ple of the United States consists of two sorts, the sea- and or long staple, and the upland or short staple. The mer, of a superior quality, is grown along the sea-coast South Carolina and Georgia. Cotton was first sown in the ited States in 1787, and was exported in small packages, led packets, in 1790. In 1800 the produce amounted to ,000,000 lbs., which has gradually increased to 480,000,000 1836, of which there were exported 386,000,000 lbs. e value of the crop was estimated to amount to 80,000,000 lars, and that of the exports to 63,000,000 dollars. A eat fall has since taken place in the price; but even at s lower rate the value of the cotton exported in the ar ending September 1838 was 61,556,811 dollars, and quantity of cotton 595,952,297 lbs. Tobacco, an in- genous American plant, has been the staple of Mary- d and Virginia from their first settlement; and it is also tensively cultivated in Kentucky, Ohio, Missouri, and er states. The quantity of tobacco exported in 1838 ounted to 100,593 hhds., in value 7,392,029 dollars; sides 75,083 lbs. snuff, and 5,008,147 lbs. of manufac- ed tobacco, amounting in value to 577,420 dollars. An e sown in rice yields from 1200 to 1500 pounds on at are called tide-lands, and from 600 to 1200 on inland ntations. Rice was first cultivated in South Carolina in 94; and its culture has been so successful that, in addi- n to the home consumption, it was exported in 1838 to amount of 71,048 tierces, of the value of 1,721,819 lars. In 1835 the quantity exported amounted to 0,851 tierces, of the value of 2,210,331 dollars. An e planted in canes yields about 1000 or 1200 pounds of gar, with an equal quantity of molasses. The necessity renewing the canes annually by planting, in consequence of the winter's frost, renders the cultivation less advantageous than in the West Indies. In 1817, however, it was calculated that 20,000,000 of pounds of sugar were made in Louisiana alone; a quantity estimated to be about two sevenths of the whole annual consumption of the United States. (Warden, ii. p. 483, 541. Morse, i. p. 668.) The culture of sugar has since been greatly extended; and in 1838 the quantity exported amounted to 408,802 pounds, and the value to 30,487 dollars;[1] besides 2,610,649 pounds of refined sugar, value 249,671 dollars.

The rural population of the United States presents an extraordinary contrast in its constituent parts to that of every country in Europe. The class of extensive proprietors living on their rents, and the class of peasants living merely by their labour, are almost equally unknown. The great bulk of the inhabitants consists of farmers, who are the owners of the lands they occupy, and the greater proportion of whom work with their own hands. "The number of those who are mere labourers," says Dwight, "is almost nothing, except in a few populous towns, and almost all these are collected from the shiftless, the idle, and the vicious. A great part of them are foreigners. Every young man hired to work upon a farm aims steadily to acquire a farm for himself, and hardly once fails of the acquisition." (Dwight's Travels, vol. iv. p. 335.) Except in some few spots near large towns, there is scarcely any land rented. The price is generally so low, that a small addition to the sum necessary for stocking a farm suffices to purchase it; and even where the value is higher, an individual who has money enough to stock a large farm will prefer buying one of half the size. Of the state of New York, only one fifth, and of the whole inhabited country east of the Mississippi (excluding Michigan and Florida), only about one tenth part is yet cleared and cultivated. Of course the best soils are first used, and, till population thickens and produce rises, soils of the second and third quality will not repay the expense of culture; and as a necessary consequence, those of the first quality yield no rent. The farms occupied by the owners are seldom large, because, where wages are high, agriculture cannot be advantageously conducted on an extensive scale; and the large property in land occasionally acquired by an individual is soon broken up by division among his children. Thus situated, the rural population certainly enjoy a greater share of happiness in the United States than in any other country in the world. They are exempted from the fluctuations incident to the commercial and manufacturing classes; they feel none of the evils of dependence, and are far above want; without possessing that wealth which engenders idleness and vanity, and often becomes a snare to its possessor. They have the means of settling their families well, without making great sacrifices; they live in the enjoyment of all the substantial comforts of life, and can look forward to old age with less anxiety and apprehension than any class of men in any other country.

The system of agriculture is necessarily less perfect in the United States than in Britain. Where prime soils can be had for almost nothing, where the price of labour is high, and that of produce low, the elaborate and costly modes of cultivation adopted in Britain cannot be advantageously applied. Some English farmers, who have gone out to America with an impression that large gains might be made by introducing our improved system of husbandry, have found themselves disappointed. Something the Americans may learn from us; but, till the country is more densely peopled, it will be more profitable to cultivate a large surface rudely than a small one laboriously. In the middle and eastern states, however, where produce brings a considerable price, farming is carried on with care and skill. In Pennsylvania, which holds the first rank as an agricultural state, in New York, Massachusetts, Connecticut, and Jersey, agricultural societies exist, and much attention is paid to the cultivation of the indigenous grasses and to the use of manures. Grazing is well understood in New England, where it is considered the most profitable species of farming. Much care has been bestowed on the breeding of sheep, and Merinos are now spread over all the northern, middle, and western states.

---

[1] Reports from the Secretary of the Treasury to Congress, with the Annual Statement of Commerce and Navigation, No. 5, p. 230, 231.

Report for 1835.

Hutchins reckoned that $\frac{13}{16}$ths of the land east of the Mississippi were covered with a strong fertile soil, and that the remaining $\frac{3}{16}$ths were occupied by lakes and rivers, or consisted of land too poor or too steep for cultivation. In 1811, Mr Blodget estimated the land under "actual improvement" to be 40,950,000 acres, or $5\frac{3}{4}$th acres for each inhabitant, a proportion which is found to be near the truth. In 1798, when a census was taken for the imposition of a tax, the quantity of land valued and taxed in sixteen states was one hundred and sixty-three millions of acres out of three hundred and eight millions, the estimated value of which was four hundred and seventy-nine millions of dollars. The value per acre varied widely. In Connecticut it was fifteen dollars per acre, in Pennsylvania six, in Georgia three fourths; but the average for the whole was about three dollars. The value of the houses was estimated at a hundred and forty millions of dollars, or two sevenths of that of the land. When new returns were procured in 1814, the value of lands and houses conjointly had risen from six hundred and twenty to one thousand six hundred and thirty millions of dollars. From these two documents, which afford a curious view of the state and growth of property in the republic, we find that, in the sixteen states organized in 1798, rather more than one half of the surface was the property of individuals. In the old states, such as Massachusetts and Connecticut, the appropriated land embraced nearly the whole surface; in New York it embraced about four sevenths, in Georgia one third. The number of acres appropriated for each individual of the population was about thirty, of which five and one half or six acres were cleared or "improved." The estimated value of the houses and lands was at the rate of 125 dollars for each individual of the contemporaneous population in 1798, but had risen to 200 dollars in 1814. Supposing every other species of property to have grown as rapidly, the rate of increase would be about $6\frac{1}{4}$th per cent. per annum, and the capital of the country must double itself in $11\frac{1}{4}$th years, or it increases twice as rapidly as the population. With a stationary population, the rate of increase would be 5·4 per cent., and the period of doubling $13\frac{1}{4}$th years. We have no similar data for other countries to found a comparison on, but we are certain that such a velocity of accumulation is unknown anywhere else.

The value of houses, lands, *and slaves*, in 1814, was, according to the returns, 1902 millions of dollars. If we add one eighth for omissions and under estimates, and for Louisiana, which was not included, with fifty millions for state lands, and two thirds additional for all other species of property (this being nearly the proportion in Colquhoun's estimate for Britain), namely, agricultural stock, manufactured goods on hand or in progress, ships, harbours, canals, roads, public buildings, &c., the whole will be 3550 millions of dollars, equal to 780 millions sterling, or about L.95 for each individual of the contemporaneous population. Colquhoun's estimate for Britain was 2700 millions sterling, or L.150 for each inhabitant. This gross amount, increasing at the rate of 6 per cent., would become 1400 millions sterling in 1824; and the annual increment, or the value added to the national capital, every year, should be about eighty millions sterling. The whole annual produce of the national industry, which affords a saving of eighty millions, cannot be less than four times as much, or 320 millions, that is, L.32 per head on the population. Colquhoun's estimate for the British Isles in 1812 was 430 millions, or L.24 per head on the population. (Colquhoun, p. 55, 65.) These calculations are founded on the returns taken as they stand. It is probable, however, that the second census would be more accurately taken than the first, and that the growth of the national capital is not quite so great as it appears.

The large profits which farming yields, the high price of labour, and the comparative scarcity of capital, are discouragements to manufacturing industry in the United States; and hence they naturally rely for a supply of manufactures on countries that have been longer settled, and where industry has made greater progress. Great Britain is a vast storehouse of ready-made goods; and it is more for the interest of an advancing and imperfectly cultivated country, such as America, to purchase with its rude produce the manufactures of Britain, than to divert her scanty capital (scanty, when compared with the boundless outlet which lies before it in the improvement of the interior wilderness) from the important business of cultivation. By this exchange, America is supplied on the easiest terms with manufactures, while Great Britain, rich in capital, and still more in art and industry, finds a vent in the increasing demands of the American people for her surplus produce, and receives in return cotton and the other raw materials of her industry. Domestic manufactures will no doubt be gradually improved in America with the progress of wealth and population. But at present they have not made nearly the same progress as in Great Britain. Yet there is no art or trade necessary for comfort or convenience which is not pursued in America; only the great manufactures of cotton, linen, woollen, iron, glass, &c., are not on the same great scale, or in such perfection, as in Britain; they are however all established, and are rapidly advancing. There are manufactures of soap, candles; of leather in all its branches; of household furniture, coaches, and other carriages; of snuff and tobacco; of paper and stationery; of printing presses and types; and printing and engraving are carried on in all their branches. There are also manufactures in all the metals; of combs and brushes, umbrellas, &c. Pianofortes are respectably made. The saw gin for cleaning cotton from the husks, and the nail-making machine, are American inventions. The woollen manufacture is almost entirely domestic, being carried on in the houses of the farmers; but the cotton manufacture is partly conducted in large works. This last, as well as several other manufactures, received a great stimulus during the last war with Britain; but they have declined since the peace, though a few of the works then established are still carried on with advantage. It was computed by a committee of Congress, that the cotton manufactures, which consumed only 10,000 bales of the raw material in 1810, consumed 90,000 in 1815, employed 100,000 hands (10,000 men, 66,000 women and girls, 24,000 boys), and produced 81,000,000 yards of cloth, valued at 24 millions of dollars. In 1835 the number of looms was estimated at 48,000, from eighty-five to ninety millions of pounds were consumed, and the value of the manufactures was computed at 50,000,000 dollars. The value of the woollen manufacture was estimated at nineteen millions of dollars, and was supposed to employ 50,000 hands constantly, and as many more occasionally. (Reports of 13th February and 6th March 1816.) The total value of the woollen manufactures has since been computed at between sixty-five and seventy millions of dollars. Broad cloths are manufactured; as are also cassimeres, satinets, flannels, blankets, carpeting, &c. Hemp and flax are manufactured in considerable quantities, but chiefly in families. Very ingenious machinery has however been applied to the spinning of cables and cordage, which are manufactured to the value of five millions of dollars. Some sailcloth is also made.

Iron being abundantly distributed throughout the country, is manufactured to a considerable extent. The quantity bar iron made in 1810 was estimated at 27,000 tons; in 30 it had increased to 112,000 tons. Of pig iron 191,536 tons were also produced, amounting in value to 13,329,760 dollars. The iron manufactures, which in 1810 amounted in value to 14,364,526 dollars, are now estimated at little short of 50,000,000 dollars. The manufacture of machinery in which iron is required, is carried to great perfection. Steam-engines of all dimensions, and every description of machinery, chain-cables, agricultural and mechanical tools of all kinds, fire-arms, nails, fire-grates, and stoves, have long been made in different parts of the United States. There is no country in which the application of the steam-engine to the purposes of navigation has been of greater practical value than in America; and the number of steamers amounted in 1838 to 800,[1] the number of steam-engines to 860, which may give an idea of the extent of this manufacture. The manufacture of spirits is carried on to a large extent throughout the United States. The materials used are grain, molasses, and fruits, chiefly the two former, from which it was estimated that the spirits distilled amounted to 25,000,000 gallons in 1810. It is stated that in 1835 4[illegible]0 distilleries had been stopt through the influence of temperance societies, but the truth of this statement is doubted. Tobacco is manufactured to the annual value of 2,[illegible]0,000 of dollars, and glass and paper to the respective values of 3,000,000 and 5,000,000 or 6,000,000 of dollars. There were in 1831 thirty chemical establishments in the United States, of which the produce was estimated at 1,[illegible]0,000 dollars a year. Cabinet-ware is made to the value of about 10,000,000 dollars; and horn, wood, ivory, and shell combs to the value of 800,000, and buttons to an equal amount. According to the returns made in the census of 18[illegible], the whole annual value of the manufactures of the United States was 127,694,602 dollars. But Mr Tenche Coxe calculated, that, making allowance for articles omitted or under-estimated, the true value would not be less than 17[illegible]700,000 dollars (L.37,500,000). Mr Pitkin, in his elaborate work on the Statistics of the United States, estimates the aggregate value of manufactures in 1835 to be from 325,000,000 to 350,000,000 dollars; and he adds, that the amount of foreign articles consumed in the country, exclusive of tea, wine, coffee, and spices, does not exceed one third of that sum. Nearly one fourth of the manufactures is in Pennsylvania; Massachusetts ranks next, then New York, Virginia, Maryland, Connecticut, North Carolina, New Jersey, Vermont, Kentucky. It may be remarked, that the effect of the high price of labour in discouraging manufactures is counteracted by three circumstances. 1. The United States being far distant from Europe, the expense of freight, and still more that of inland carriage, makes a material addition to the prime cost of all bulky or heavy articles. 2. As the use of machinery comes to be substituted more and more for manual labour, the disadvantage of high wages gradually vanishes; and the Americans, who possess great mechanical genius, have the means of procuring steam and water power to an unlimited extent. 3. The American women prefer working in factories to domestic service, which they consider degrading; and hence female labourers are not scarce, and may be procured at moderate wages.[2]

Commerce.

The commerce of the United States has gradually expanded to a vast extent, and has made much greater progress than manufactures. The Americans are not surpassed in activity and enterprise by any other nation; and the surplus produce, which in every country is the means of its foreign trade, naturally increases with the progress of cultivation. The wars and convulsions of Europe consequent on the French Revolution threw a great proportion of the general carrying trade into their hands; and in the interval from 1790 to 1807, their exports increased from 20 millions to 108 millions of dollars. But in the course of the war, Great Britain and France differed concerning the respective rights of the neutral and the belligerent; and this dispute ended in their defiance of all those maxims of public law which formerly restrained the rage of war. They refused any longer to recognise the rights of the neutral trader; his merchandise was considered to be lawful prey. France issued the Berlin decrees for the seizure and confiscation of all British goods on the land, which were ordered to be consumed in the flames; and Great Britain issued her orders in council for the proscription of all trade with France by sea, and for the detention of all vessels bound to a French port. Lawless violence thus reigned, and the unprecedented outrages which followed gave a sudden check to the growing trade of the United States, from which it did not recover and attain its former extent till the year 1835. The progressive increase of the American trade will be seen from the following table of the exports and imports of the country from the year 1791 to 1838 inclusive.

ar.	Exports, in Dollars.		Total.	Imports, in Dollars.	Year.	Exports, in Dollars.		Total.	Imports, in Dollars.

[1] See Report of the Select Committee to Congress, on the subject of Steam-Engines, December 13, 1838.

[2] Seybert, 6, 8. Mellish, 90. Warden, iii. 262. Fearon, 339, &c.

The two following tables contain an account of the exports from the United States, and of the merchandise imported in return. A third table is added of the different countries to which the produce of America is exported, and from which other articles are brought in exchange. These tables are official documents laid before Congress, and they afford an ample view of the value and progress of the American trade.

Summary Statement of the Value of the Exports of the Growth, Produce, and Manufacture of the United States, during the Year ending on the 30th day of September 1838.

	Dollars.
AGRICULTURE.	
Products of Animals—Beef, tallow, hides, horned cattle, 528,231; butter and cheese, 148,191; pork (pickled), bacon, lard, live hogs, 1,312,346; horses and mules, 331,620; sheep, 20,462	2,340,850
Vegetable Food—Wheat, 8125; flour, 3,603,299; Indian corn, 141,992; Indian meal, 722,399; rye meal, 110,792; rye, oats, and other small grain, 94,533; biscuit, or ship bread, 263,686; potatoes, 56,898; apples, 41,121; rice, 1,721,819	6,764,664
Tobacco	7,392,029
Cotton	61,556,811
All other agricultural products—Flaxseed, 55,954; hops, 53,602; brown sugar, 30,487; indigo, 50	140,093
MANUFACTURES.	
Soap and tallow candles	513,721
Leather, boots, and shoes	132,476
Household furniture	281,683
Coaches and other carriages	42,207
Hats	102,652
Saddlery	38,909
Wax	67,181
Spirits from grain, beer, ale, and porter	165,316
Snuff and tobacco	577,420
Lead	21,747
Linseed oil and spirits of turpentine	94,295
Cordage	21,547
Iron—Pig, bar, and nails, 102,523; castings, 33,451; all manufactures of, 573,434	709,408
Spirits, from molasses	99,473
Sugar, refined	249,671
Chocolate	3,315
Gunpowder	162,234
Copper and brass	81,363
Medicinal drugs	112,601
Cotton, piece-goods—Printed and coloured, 252,044; white, 3,250,130; nankeens, 6017; twist, yarn, and thread, 168,021; all other manufactures of, 82,543	3,758,755
Flax and Hemp—Cloth and thread, 1244; bags, and all manufactures of, 2146	3,390
Wearing apparel	259,194
Combs and buttons	47,629
Brushes, billiard-tables, and apparatus	6,939
Umbrellas and parasols	12,967
Leather and morocco skins, not per lb	28,071
Printing presses and types	34,681
Fire-engines and apparatus	2,784
Musical instruments	8,604
Books and maps	50,913
Paper, and other stationery	94,535
Paints and varnish	22,410
Vinegar	5,241
Earthen and stone ware	12,019
Manufactures of glass, 37,881; tin, 10,179; pewter and lead, 6461; marble and stone, 5199; gold and silver, and gold leaf, 5519	65,239
Gold and silver coin	472,941
Artificial flowers and jewellery	11,756
Molasses	6,620
Trunks	2,385
Bricks and lime	31,322
Domestic salt	67,707
Articles not enumerated—Manufactured, 392,217; other articles, 587,761	979,978
THE FOREST.	
Skins and furs, 633,945; ginseng, 36,622	670,567
Products of Wood—Staves, shingles, boards, &c., 2,102,053; other lumber, 267,134; masts and spars, 36,150; oak bark, and other dye, 161,694; all manufactures of wood, 549,165	3,116,196
Naval Stores—Tar, pitch, rosin, and turpentine, 703,394; ashes, pot and pearl, 710,342	1,413,736
THE SEA.	
Fisheries—Dried fish, or cod fisheries, 626,245; pickled fish, or river fisheries (herring, shad, salmon, mackerel), 192,758; whale and other fish oil, 1,556,775; spermaceti oil, 137,809; whalebone, 321,458; spermaceti candles, 340,531	3,175,576
Total	96,033,821

Value of Merchandise Imported into the United States during the Year ending 30th September 1838.

Species of Merchandise.	Value in Dollars.
FREE OF DUTY.	
Articles for the United States	30,316

From these tables it will be seen, that foreign produce or manufactures constitute about one ninth of the exports. The leading articles chiefly consist of the produce of the land. Cotton forms about 60 per cent. of the domestic exports; wheat, Indian corn, and other bread-stuffs, 10 per cent.; tobacco 12 per cent.; lumber, bark, &c. 3½ per cent.; horses, beef, &c. 2½ per cent. The leading imports are the fine products of the loom in wool, cotton, silk, and linen, or articles not raised in the country, such as tea, coffee, sugar, and wine. In hemp, iron, and leather, the imports are small. Nearly one half of the whole imports come from Britain, and only about one seventh from France.

The internal and coasting trade of the United States has increased more rapidly than their foreign commerce, and is undoubtedly far greater than that of any other state with an e al population. The enrolled and licensed tonnage, v ich was only 184,000 tons in 1795, had risen to 588,000 i 1821, and in 1838 to 1,133,999. It now exceeds the r istered tonnage, of which it formed only one third in 1 05. The Hudson is the great channel of inland trade f districts containing nearly two millions of inhabitants, a l is rapidly advancing, both in its commerce and navi g ion. The Delaware, Susquehannah, Potomac, and other la ge rivers farther south, all exhibit an active and growing tr fic. The vessels on the majestic Mississippi, though th y do not yet equal those on the Hudson, are fast increas i with the progress of cultivation and commerce.

Steam-vessels.

The application of steam to the propelling of vessels forms a great era in the history of navigation. It is perhaps one of the greatest practical discoveries of which modern times can boast. It even effects a greater improvement in the intercourse by sea, than the railroad in that by land; and perhaps no other country, owing to natural advantages, has derived such incalculable benefits from it as America. From the rapidity of the vast rivers by which the country is intersected, the navigation against the stream by means of wind and sails was seldom practicable; and as the voyage downward was speedy and certain, the upward voyage was in proportion tedious. Accordingly, the boats that brought down the produce of the interior from the Ohio and other streams to New Orleans, were generally broken up and used for fire-wood, and the crew were thus compelled to retrace their course by land. But the power of steam, unlike the fickle gale, is equable and constant. It can at all times be relied on; and, surpassing in force the raging torrent, it propels the vessel with the same certainty through the adverse waters as in the downward voyage. Some such agency was required to facilitate the navigation of rivers, and to turn to full account the advantages which they afford for internal intercourse. A voyage from New Orleans to Pittsburg against the current of the Mississippi, running from four to six miles an hour, generally occupied six weeks; it now does not occupy as many days. What a boundless field is here opened for steam-navigation, which accordingly is universally extended through the whole country. Experiments were made at an early period, both in America and elsewhere, for propelling vessels by steam. The idea was broached in England in 1736, in France in 1782, and various trials were made in America from 1783 to 1787. A steam-vessel was actually constructed by Mr Miller of Dalswinton, and was seen sailing on the Clyde about this period; but the discovery was not followed out. It was however from his model that Mr Fulton constructed in 1807, on the Hudson river, in the state of New York, his first steam-vessel, which, with an engine of only eighteen horse-power, made the passage between Albany and New York, a distance of 160 miles, in thirty-three hours. The whole number of steam-vessels in the United States was estimated, from the information collected by the select committee on steam-engines, and laid before Congress, at 800 in December 1838. Of these, nearly 400 are now computed to be running on the western and south-western waters, comprising chiefly the Mississippi and its tributary streams, where none was used till 1811, and where in 1834 the number was computed to be only 234. On the Ohio, the number of passages by steam-vessels through the Louisville Canal, which in 1831 was 406, had increased in 1837 to 1501, or nearly fourfold in six years. About seventy steam-vessels were running in 1838 on the north-western lakes, where in 1825 there were only twenty-five. Of the whole number, nearly 800, sailing in 1838 chiefly on the American rivers, 140 belong to the state of New York. Of these, very few are sea-going vessels. The government of the United States never owned more than two steam-vessels of war, one of which is now lost; though about thirteen other steam-vessels are employed by the war department on the public works, and in the transportation of troops and stores. The steam-boats in the United States are computed at 60,000 tons. The largest of those that run between New York and Mississippi is supposed to be 860 tons, and nearly 300 horse-power. There are two on Lake Erie of 755 and 700 tons. The chief places for the construction of steam-vessels and their engines are, Pittsburg, Cincinnati, and Louisville, on the western waters; and New York, Philadelphia, and Baltimore, on the Atlantic.[1] Owing to the numerous and fatal accidents that have befallen steam-vessels in the United States, the subject was early investigated, under the directions of Congress, when ample information was obtained from every part of the Union respecting the causes and consequences of these casualties. A stringent enactment had been previously passed by this active and energetic government, ordaining, under heavy penalties, increased caution in the management of this craft; frequent examinations, by qualified persons, of the nature and strength of the machinery; and prosecutions against the officers and owners for injuries to life and property; thus evincing that vigilance and laudable anxiety for the public safety which so well merits the confidence of the people. Another law, it is expected, will follow, providing for the employment of careful and skilful engineers.

---

[1] See Report from the Secretary of the Treasury, with the Annual Statement of Commerce and Navigation, ending on the 30th Septem b 1838.

Those accidents that have occurred to steam-vessels are computed to have amounted to 260; ninety-nine occasioned by explosions of the boilers, or the bursting of some part of the engines, or by collapses; twenty-five by shipwreck from collision, gales, &c.; twenty-eight by fire; fifty-two by snags or sawyers, which are trees that, having been swept away by floods, have, in their course down the river, stuck in the bottom, and there remain, moving up and down, and have, from the resemblance of their motion to sawyers, received that name. They are extremely dangerous to vessels that run against them. Different and unknown causes have occasioned the loss of twenty-four steam-vessels. "The general impression," says the secretary at war in his letter, "is, that a great part of the boats destroyed by explosions, as well as many lost by fire and other accidents, would have been saved by proper experience, science, and attention, on the part of the engineers and commanders." Such accidents are in all cases occasioned by ignorance or carelessness; and it is highly necessary that the agency of steam, as it is so powerful and useful, should be also rendered comfortable and safe. This has not been the case in America; and the frequent explosions which have occurred with loss of life, give an impression of recklessness and mismanagement, highly disgraceful to those in the immediate charge. In this country such evils could not have continued so long. They would have been put down by the scandal which they would have excited, even by the force of public opinion, without the aid of laws.[2] The number of lives lost in these various accidents is differently stated. The lowest amount is stated at 2000; though, according to other accounts, it is double or triple. The secretary to the treasury states that he had been able to ascertain 1676 killed and 443 wounded in steam-boats. By the sinking of a vessel on the Mississippi in 1837, 300 lives were lost, which is the greatest number by any one accident. By the explosion of a vessel on the same river in 1838, 130 lives were lost, and 120 by that of another on the Ohio. By the burning of a vessel on the Mississippi in 1837, 130 persons perished; and 100 by shipwreck in the same year on the North Carolina shore. The loss of property from the same cause is estimated at between five and six millions of dollars.

Canals and railroads.

The internal intercourse of the United States has been wonderfully improved by the construction of canals, which fill up the blanks left by nature in the water communications of the country, and more recently by railroads, which now intersect the American territory in all directions. Plans of improvement, which, when they were proposed, were regarded as visionary, have been actually executed, and have far outstript the most sanguine hopes of their projectors. Capital to a prodigious amount has been laid out on these improvements, which have already produced, and are destined to produce still more, mighty changes in the internal intercourse and general aspect of the world. In a few years they will connect the St Lawrence with the Gulf of Mexico, and the Atlantic with the Mississippi. Nor need we wonder if we yet see the railroad car speeding its course, on wings of fire, from New York, along the great table-land of New Spain, to Mexico. The following account of the canal navigation of the United States is abridged from Mitchell's Compendium of the internal Improvements of the country.

Maine.—The only canal of any importance in this state is Cumberland and Oxford Canal, which extends from Portland to Sebago Pond. By means of a lock constructed in Songo river, it is connected with Brandy and Long Ponds, and comprehends a water communication, natural and artificial, of about fifty miles in extent. It was completed in 1829, at an expense of 250,000 dollars.

New Hampshire.—The internal improvements in this state consist of a series of short canals, constructed on the Merrimack river, for the improvement of its navigation, by means of which, and the Middlesex Canal, Boston is connected with the interior of New Hampshire.

Vermont.—There are several short canals constructed in this state on the western bank of the Connecticut river, intended principally for improving the navigation of that river.

Massachusetts.—The Middlesex Canal, in connection with those in New Hampshire, opens a water-communication between Boston and the interior parts of that state. It connects the Merrimack river with Boston harbour, and extends from Charlestown, opposite Boston, to Chelmsford, twenty-seven miles. It was completed in 1808, at an expense of 528,000 dollars. The Blackstone Canal commences at Worcester, Massachusetts, and extends to Providence, Rhode Island. It was completed in 1828, at an expense of 600,000 dollars. The Hampshire and Hampden Canal, uniting with the Farmington Canal at Southwick, and extending thence to Northampton, twenty miles, connects the Connecticut river with New Haven harbour. The entire distance is seventy-eight miles. It was commenced in 1825, and finished at an expense of 600,000 dollars. There are other two canals, constructed for passing two falls in the Connecticut river.

Connecticut.—The Farmington Canal, in Connecticut, commences at New Haven, and passes through the state fifty-eight miles, to its northern boundary, where it is connected with the Hampshire and Hampden Canal in Massachusetts.

New York.—The Erie Canal is by far the most important work of the kind in the United States, or indeed in the world. It was commenced in 1817, and completed in 1825. It unites the Hudson with Lake Erie, extending from Albany, on that river, to Buffalo on Lake Erie, a distance of 363 miles, with a width at the bottom of twenty-eight feet, at the surface of forty feet, and a depth of water of four feet. The number of locks is eighty-four, and the rise and fall 698 feet. This great work was begun without any sanguine hopes of success, and was generally pronounced to be vain id chimerical; and four years after its commencement, ie revenues derived from the tolls were estimated at the w rate of 150,000 dollars a year, whereas they amount- l for the first ten years after its completion to ten millions 'dollars; and the tonnage brought down by the canal, hich was estimated, with a fear of its being deemed ex- avagant, at 250,000 tons, actually exceeded, in 1836, 300,000 tons. The whole debt incurred in the construc- on of this canal is now paid off, and it yields, over all ex- nses, a considerable surplus, which is expended on other iblic works. This however is one of the most successful idertakings in the United States. There are others of iich the revenue hardly pays the expense of repairs. it the influence of this great work on the general pros- rity of the country has been still more remarkable. It s given a wonderful impulse to the agriculture of the in- ior; it has converted deserts into fruitful fields. Flourish- towns have been seen to spring up in its track. Albany, ica, Rochester, and Buffalo, have, from the facilities of mmunication which it has afforded, the two first doubled eir respective populations within ten years, and that of the o latter has increased, Rochester from 5271 in 1825, to ,404 in 1835, and Utica from 2600 to 15,661. Champlain inal extends farther from Whitehall, on Lake Champ- n, to Albany, a distance of sixty-three miles. Oswego nal, a branch of the Erie, connects Lake Ontario with Erie Canal. It is thirty-eight miles in length. Cayu- and Seneca Canal extends from Geneva, on Seneca ke, to Montezuma, on Erie Canal, a distance of twenty les. Chemung Canal extends eighteen miles from the ad waters of Seneca lake to the Chemung or Tioga river. ienango Canal extends from the Erie Canal, near Utica, Oneida county, to Binghampton in Broome county, Susquehannah river, in length 93¾ miles. Black River nal extends thirty-six miles, from Rome to the high falls the Black River. The net revenue received from the ie and Champlain Canals was, for the year ending Sep- mber 1834, 1,035,644 dollars. The other canals have t been profitable. The following is a statement of the ferent canals already constructed by the state, and of the pense of their construction.

---

[1] See Letter of the Secretary of the Treasury to the Speaker of the House of Representatives, December 12, 1838, p. 11.

[2] It appears that a prejudice had arisen in favour of copper boilers, which, as copper is inferior to iron in tenacity, were not so safe. But one of the proprietors or managers of steam-boats said it was impossible to disabuse the people of this error; and that unless they used a boiler of this metal, a vessel would be built, and provided with a copper boiler, and run against them. So, this person adds, in a tone of reckless levity that cannot be too severely reprobated, "we have concluded, therefore, to give them a copper boiler, the strongest of its class, and have made up our minds that they have a perfect right to be scalded by copper boilers if they insist on it." "I lament to add," says Wm. C. Redfield, the writer of the excellent letter to the secretary to the treasury, in which this anecdote is given, "that the exercise of this 'right' to the use of copper was attended, within a few years, with a fearful destruction of life, as had been foretold."

	Length.	Dollars.
Erie Canal	372 miles	7,143,789
Champlain	79	1,257,604
Oswego	38	565,437
Cayuga and Seneca	23	236,804
Chemung	39	331,693
Crooked Lake	8	156,776
Chenango	97	2,270,605
		11,962,711

All these may be considered as constituting one work, main object of which is to connect the valley of the idson with that of Lake Champlain on the north, and great central basin of the Canadian lakes on the west; ile, by the various lateral canals, the produce of the ighbouring countries is brought into the main track, and produce of foreign countries transported into the inmost esses of the state.[1] The Delaware and Hudson Canal, dertaken by a joint-stock company, extends from the idson river, ninety miles above New York, in a south- st direction, to Port Jervis on the Delaware, fifty-nine les, where it unites with the Lackawaxen Canal, proceeds the left bank of the Delaware to Lackawaxen Creek, nce to Honesdale, the termination of the canal, 108 les. It was completed in 1828. There are several other onsiderable canals within this state.

United States.

New Jersey.—The Morris Canal, in this state, extends from Jersey city on Hudson river, across the state of New Jersey, to Delaware river, opposite Easton, Pennsylvania, where it connects with the Lehigh Canal; the distance being 101 miles, the expense nearly two millions of dollars. The Delaware and Raritan Canal extends from Bordentown, on Delaware river, to New Brunswick, on the Raritan, forty-two miles. In this state there are several other inconsiderable canals.

Pennsylvania.—The main division of the Pennsylvania Canal commences at Columbia, at the termination of the Columbia Railroad, passes up the bank of the Susquehannah to the mouth of the Juniatta river, and thence to Holidaysburg, at the eastern base of the Alleghany Mountains; its length being 171 miles. The western division commences at Johnstown on the Conemaugh, pursues the course of that stream, and also that of the Kiskiminitas and Alleghany rivers, and finally terminates at Pittsburg. In connection with the Columbia Railroad, it forms a grand chain of communication between the eastern and western parts of the state, the distance from Philadelphia to Pittsburg being about 395 miles. It is proposed to extend this communication to the town of Beaver, so as to unite with the Beaver division. The distance is only twenty-five miles; and this, with a proposed canal from Newcastle to Akron on the Ohio and Erie Canal, would, with the exception of the passage over the Alleghany Portage Railroad, of thirty-six miles, form a water-communication from Philadelphia to New Orleans of 2435 miles. The Susquehannah division of the Pennsylvania Canal leaves the main division at the mouth of the Juniatta, and passing up the west bank of the Susquehannah river, intersects the north branch and west branch divisions at Northumberland. Its length is thirty-nine miles. The north branch division commences at the termination of the Susquehannah division, and passes along the right bank of the north branch of the Susquehannah. The west branch division commences at the same point as the north branch division, and is carried along the left bank of the west branch of the Susquehannah. The Beaver division of the Pennsylvania Canal commences at the town of Beaver on the Ohio river, twenty-six miles below Pittsburg, and ascends the valley of the Ohio river, and its tributary the Chenango Creek, to its termination in Mercer county, a distance of forty-six miles. It is intended, by a farther extension of this canal, to connect Lake Erie with the Ohio; and by another canal from Newcastle on the Beaver division, twenty-four miles above the town of Beaver, along the valley of the Mahoning river to Akron, a distance of eighty-five miles, to connect the canal navigation of the Ohio with that of Pennsylvania; and thus a water-communication being opened to Philadelphia, that city will rival New York as the maritime emporium of the western states. At present the valuable produce of these rising states is carried through Lake Erie, the navigation of which is frequently dangerous, and the Erie Canal, to New York, a distance of 760 miles, while the route by the proposed series of canals to Philadelphia is not above 575 miles. This route would also possess this additional advantage over that by the Erie Canal, that it would not be interrupted for so long a time by the winter frosts. All traffic on the Erie Canal is suspended during five months of the year, it being seldom navigable till the 20th April, and rarely after the 20th November; while, from the milder climate of Pennsylvania, its canals are open from the 10th March to the 25th December. When all the projected lines of intercourse by canals and railroads are completed in Pennsylvania, from Pittsburg to Philadelphia, the merchants of the latter city will be enabled to monopolize the western trade during the

---

See Trotter's excellent work, chap. vii. 134, on the Financial Position and Credit of the States of the American Union, which contains ple details respecting the internal improvements of the United States.

commencement of spring and autumn, the busiest seasons of the year.

The Delaware division commences at Bristol, eighteen miles above Philadelphia, and passes thence in a direct line to Morrisville, opposite Trenton, a distance of fifty-nine miles. This is the channel by which the coal-trade of the Lehigh reaches Philadelphia. The Schuylkill Canal extends from Philadelphia to Reading, and thence to Mount Carbon, a distance of 108 miles. The Union Canal connects the borders of the Susquehannah with those of the Schuylkill, and is in length eighty-two miles. The Lackawaxen Canal commences at the termination of the Delaware and Hudson, and unites with a railroad at Honesdale, a distance of forty-nine miles. The Lehigh Canal extends from Easton, on Delaware river, to Mauch Chunk; its length being $46\frac{3}{4}$ miles. There are several other smaller canals, chiefly for improving the navigation of the Susquehannah river.

Delaware.—The Chesapeake and Delaware Canal connects Delaware river with Chesapeake Bay. It is fourteen miles in length, and was constructed at the immense expense of 2,200,000 dollars, owing to its size, being sixty-six feet broad at the surface, and eight feet deep, and to the depth of its excavations and the extent of its embankments.

Maryland.—The Chesapeake and Ohio Canal, commenced in 1828, is a great undertaking, which, extending from the tide-water of the Potomac river, above Georgetown, in the district of Columbia, and terminating at Pittsburg in Pennsylvania, a distance of $341\frac{1}{4}$ miles, would connect the Atlantic with the Ohio and the Mississippi, terminating in the Gulf of Mexico. The breadth of this canal, which would be a splendid improvement, is from sixty to eighty feet at the surface, and fifty at the bottom. In the year 1835 it was only completed to the distance of 100 miles. The undertaking languished for want of funds. The estimated expense is 3,650,000 dollars. The district of Columbia has two branches connected with the above canal.

The Dismal Swamp Canal, in Virginia, connects Chesapeake Bay with Albemarle Sound; and various other small canals have been constructed for improving the navigation of James River, by avoiding the falls which interrupt the navigation. They may be considered as the commencement of a series of improvements, by which the waters of James river may be connected with the Great Kanawha, one of the head streams of the Ohio, and a short and direct communication thus opened from the Atlantic, into which the James river falls, to the Mississippi and the Gulf of Mexico. Companies have also been formed to improve the channels of the Roanoke and its confluents in both Virginia and North Carolina. The canals in South Carolina are small, and chiefly have in view to improve the navigation of the different streams which water this state, namely, the Catawba, the Saluda, the Wateree, and others. In North Carolina there is a canal which connects North-West River with the Dismal Swamp Canal, and others for improving the navigation of the Roanoke and other streams. In Georgia there is only one canal which unites the waters of the Ogeechee with those of the Savannah. In the state of Kentucky there is a small canal for avoiding a fall on the Ohio; and in Tennessee similar improvements are projected for improving the river of that name.

Ohio.—The canal navigation of this state is of great magnitude and importance, and further improvements are in progress. The Ohio and Erie Canal, completed in 1832, commences at Cleveland, at the mouth of the Cuyahoga, and, passing through a number of towns in its route, joins the Ohio river at Portsmouth, connecting it with Lake Erie. The main trunk is 310 miles in length, and, including its branches, the total length is 334 miles. This canal has been a most successful undertaking, and has in many places through which it has passed quadrupled the value of private property. The Miami Canal commences at Cincinnati and terminates at Dayton. An extension of this work is in progress, by which it will be connected with the Wabash and Erie Canal at Defiance. The expense of these two canals has been 5,500,500 dollars. The total length of canals in Ohio is 409 miles. The net revenue on these two canals was, for the year 1834, ending in October 31, 191,444 dollars. Other plans are in contemplation for extending branches from this canal in different directions. It is proposed, by the Mahoning and Beaver Canal, to connect it by a canal eighty-five miles in length with the Beaver division of the Pennsylvania Canal, by which a communication would be secured to the western states with the Atlantic section of the Union, and a choice would thus be afforded them of two, and eventually, when the Baltimore and Ohio Railroad and the Chesapeake and Ohio Canal are completed, of three great outlets for their produce.

Indiana.—The Wabash and Erie Canal, in this state, extends from near Lafayette, on the Wabash river, up the valley of that stream, across to the Maumee at Wayne, 105 miles. This work is to be carried from Wayne to the east boundary of the state, where, uniting with that part of it authorized by the state of Ohio, the whole distance will be 187 miles. Other canals are proposed in this state, some as branches from the main trunk of other canals already made, and others new.

In the western states, Alabama, Mississippi, and Louisiana, there is no extent of canal navigation, and those which are projected are chiefly for improving the navigation of the streams that abound in the country.

A canal across the peninsula of Florida has for some years been considered an object of national importance, and would greatly facilitate the transmission of the produce and merchandise constantly passing and repassing to an immense amount between the seaports on the Gulf of Mexico and the Atlantic region of the United States, and at present carried by a dangerous navigation among the Bahama Islands and around the southern point of Florida, where the loss of shipping has been so great that it is estimated to have been nearly equal to the expense of the proposed canal.

The railroad is a still more striking and splendid improvement than the canal, and affords even greater facilities to internal intercourse. This great improvement is marvellously aided by the power of steam, by which the speed may be indefinitely increased; so that the time spent in travelling hundreds of miles is no longer counted, as formerly, by weeks, or even days, but by hours, and the remote extremities of a kingdom appear to be brought nearer than were formerly those of the same county. The enterprising spirit of the Americans has eagerly laid hold of this singular improvement, which they are rapidly extending in all directions. We shall endeavour to give a short notice of such as are connected with the great communications of the country, omitting those which, being more local, are of less importance.

Massachusetts.—In this state, Boston is the centre from which the railroads diverge in different directions. 1. The Boston and Worcester Railroad, which extends south-west to Worcester, $43\frac{1}{4}$ miles, at an expense of 900,000 dollars, and which it is proposed to carry into the state of New York, and to connect with the New York and Albany Railroad at Greenbush, opposite to Albany, the whole distance being about 200 miles. 2. The Boston and Providence Railroad, which extends in a straight line south from Boston to Providence, Rhode Island, 42 miles, and which will connect with the Stonington and Providence Railroad, making the distance to Stonington $90\frac{1}{2}$ miles. 3. The railroad from Boston westward to Lowell, 25 miles, which is considered the commencement of a series of railroads, still westward, through the states of New Hampshire and Vermont, to a point in Lake Champlain, opposite Plattsburg, and thence across th state of New York to Ogdensburgh on the St Lawrence rir, the entire distance being about 335 miles. A railroad exends from Boston to Taunton, thirty-two miles, which it is prosed to unite with the Boston and Providence Railroad at haron, eighteen miles from Boston. It is also proposed to xtend the Worcester Railroad to Norwich, a distance of six miles.

ew York.—The Mohawk and Hudson Railroad extends fro Albany to Schenectady, about fifteen miles, and affords communication between the tide-water of Hudson river and the Erie Canal. It is continued by the Saratoga and Schenectac Railroad, twenty-one miles, to the villages of Ballston Sp and Saratoga, which it unites with the line of steam-navigation upon the Hudson. The Ithaca and Oswego Railroad exnds from the village of Ithaca, at the head of the Cayu lake, twenty-nine miles, to the village of Oswego on the Susquehannah river. The Haerlem Railroad is from Ne York to that city. The Rensselaer and Saratoga Railroa in length twenty-five miles, commences at and crosses the Hudson at Troy, and passes to Waterford, and thence to llston Springs. The Catskill and Canajoharie Railroad extnds between the two places, a distance of seventy miles. Th Utica and Schenectady Railroad, between these two plas, extends 100 miles. Railroads are besides projected, 1st, fro New York to Lake Erie, with a capital of 10,000,000 dollar 2d, from New York to the Hudson, opposite Albany; 3d, om Newburgh to the Delaware river, distance fifty-one mil; 4th, the Brooklyn, Jamaica, and Long Island Railroa from Brooklyn to Greenport, about 100 miles, thence by eam-boat to Stonington, thirty-five miles, then by railads now in progress through Providence to Boston, 90 miles; total from New York 225½ miles. This work was ommenced in 1835. In 1832, various companies were incporated for railroads in different directions, which would reqre a capital estimated to amount to 12,000,000 dollars.

w Jersey.—The chief railroads in this state are, the Calen and Amboy Railroad, ninety-six miles in length, whi unites the two great cities of Philadelphia and New Yo; the Paterson and Hudson Railroad, extending from Patson to Jersey city on the Hudson, opposite to New Yo, sixteen miles in length; the New Jersey Railroad, extenng from New Brunswick to Jersey city, opposite New Yo. The New Jersey, Hudson, and Delaware Railroad is iended to unite the Delaware with the Hudson, opposite Ne York.

nnsylvania.—The Philadelphia and Columbia Railroad extds 81½ miles in length, from the former city to Columbia n the Susquehannah. The cost, including engines, is estiated at 3,595,809 dollars. From this railroad branches extd in different directions to Westchester, twenty-one mil; and about forty miles from Philadelphia the Oxford Raiad, passing through Oxford, terminates at the south line f the state, where it will unite the Baltimore and Port Desit Railroad; the distance being twenty-one miles.

leghany Portage Railroad commences at Holidaysbur the termination of the main division of the Pennsylvan Canal, and crossing the Alleghany Mountains at Blair's Ga Summit, descends to its final termination at Johnstown, wh it intersects the western division of the canal, being a diance of 36½ miles. There are railroads from Philadelphi o Germantown, seven miles, and to Morrisville, opposite Trenton, twenty-six miles.

e Central Railroad commences two and a half miles beyon Pottsville, and extends 44½ miles to Sunbury, opposite e forks of the Susquehannah river. There are besides nurous railroads on a smaller scale from the coal-mines whi are found in this state, or connected with the main can or railroads which are formed.

laware.—The Newcastle and Frenchtown Railroad extds 16½ miles from Newcastle on Delaware river to Frehtown in the state of Maryland, and affords a direct communication between Delaware river and Chesapeake Bay. The Wilmington and Susquehannah Railroad will extend 26½ miles from Wilmington to Semper's Point on North-East Bay, which communicates with Chesapeake Bay near the mouth of the Susquehannah river.

Maryland.—The Baltimore and Ohio Railroad, begun in 1828, will extend from Baltimore to Pittsburg, Pennsylvania, thus affording a communication between the waters of the Chesapeake Bay and those of Ohio. A farther extension of thirty miles will carry it to Williamsport, and another of seventy-five miles to Cumberland, a country abounding in rich bituminous coal, making the whole distance 325 miles.

Baltimore and Susquehannah Railroad, commenced in 1830, extends seventy-six miles in length, from Baltimore to York. A railroad from York to Columbia, eleven miles in length, which was sanctioned by the Pennsylvania state legislature in 1835, will unite the Baltimore, and Susquehannah, and Philadelphia, and Columbia Railroads, and will form a railroad communication between the cities of Philadelphia and Baltimore, 168 miles in length. Branches are proposed from this railroad, to improve the communications of the country; one from Baltimore, in length fifty-two miles, to join with the Oxford Railroad, and to form a railroad communication of 117 miles between the cities of Baltimore and Philadelphia.

Virginia.—The Petersburg and Roanoke Railroad extends from Petersburg to Blakeley, North Carolina, at the foot of the Roanoke Canal, a distance of fifty-nine miles. The Portsmouth and Roanoke Railroad, seventy-seven miles in length, commences at Portsmouth, opposite Norfolk, and terminates at the head of the Roanoke Falls, a short distance below the Petersburg branch. The Winchester and Potomac Railroad extends from Winchester to Harper's Ferry, about thirty miles, where it unites with the Baltimore and Ohio Railroad. This is an important link in the great chain of communication now extending in the southern section of the Union; and measures have been taken to continue it through the great valley of Virginia towards Tennessee. The Richmond, Fredericksburg, and Potomac Railroad is to extend from the river Potomac, at the mouth of the Potomac creek, through Fredericksburg, to Richmond, about seventy-five miles. This work connects at Richmond with the Richmond and Petersburg line, twenty-one miles long, and, with the Petersburg and Roanoke Railroad, will form a continued railroad communication from the Potomac to the Roanoke rivers of 155 miles in length. Railroads are also proposed from Fredericksburg to Guyandot on the Ohio river; from Richmond to Lynchburg, thence to Knoxville, Tennessee; and from Lynchburg to New River.

North Carolina.—Cape Fear and Yadkin Railroad commences at Wilmington, and extends to the Yadkin river by the way of Fayetteville; thence to Beatty's Ford, or some other point on the Catawba river, a distance of about 230 or 250 miles. This work is advancing very rapidly. A railroad is begun from Newbern, on the Neuse river, through Raleigh, to Clinton on the Yadkin. The Roanoke, Raleigh, and Fayetteville Railroad will begin at the termination of the Petersburg and Roanoke Railroad, and will extent to Fayetteville.

South Carolina.—The South Carolina Railroad, begun in 1830 and finished in 1833, in length 135¼ miles, commences at Charleston, and terminates at Hamburg on the Savannah river, opposite Augusta. At Augusta the Augusta and Athens Railroad will connect with it, which it is proposed to carry on westward to unite with the Tuscumbia, Courtland, and Decatur Railroad in Alabama, and the great Tennessee Railroad to Memphis on the Mississippi, which when finished will be one of the most important works in the Union. The Columbia and Branchville Railroad will extend from Columbia to Branchville, where it will unite with the South Carolina Railroad. This work was about to be begun in 1835; as also the Peedce and Wateree Railroad, to extend from Cheraw to Charleston, 153 miles; the Edgefield Railroad, to run from Aiken to Charleston, 137 miles; a railroad to extend from Cheraw to Columbia, eighty-eight or ninety miles; another from Barnwell to a point on the South Carolina Railroad, and likewise from Beaufort to Hamburg on the Savannah river, 110 or 112 miles in length.

Georgia.—The Savannah and Macon Railroad is 210 miles between these two places. The Augusta and Athens Railroad is 114 miles between the two places, and may be considered as an extension of the South Carolina Railroad. When the whole work is finished, the route from Charleston to Memphis will be 700 miles. A railroad is projected from Augusta to Columbus on the Chattahoochee, twenty miles in length, with other railroads branching from it.

Florida.—A railroad is to extend from Tallahassee, the capital, twenty-two miles, to the town of St Mark's, to be carried to Jacksonville on the St John's river, 150 miles.

Alabama.—The Tuscumbia, Courtland, and Decatur Railroad extends from Tuscumbia to Decatur, forty-five miles. The Daletown, Woodville, and Greensborough Railroad, is to extend from Daletown, on the Alabama river, northward through Woodville to Greensborough, fifty miles; the Florida, Alabama, and Georgia Railroad, to run from Pensacola in Florida, crossing the Escambia river about twenty-two miles above that place, thence in a north-east direction to Columbus, Georgia, on the Chattahoochee river, about 210 miles. Railroads are also proposed from Montgomery to Columbus, Georgia, 100 miles in length; from Montgomery to Decatur on the Tennessee river, about 200 miles; and from Tuscaloosa to Decatur, about 120 miles. Partly by the Tennessee and Alabama Railroad, partly by a water-communication from the Hiwassee, a considerable tributary of the Tennessee, which rises in the mountains of Georgia, it is proposed to continue a line to Selma on the Alabama, 371 miles, and to Mobile, 600 miles.

Mississippi.—Several railroads have been projected in this state, the most important of which is the Natchez and Jackson Railroad, in extent about ninety miles between those places, and onwards to Livingston, thirty-one miles more.

Louisiana.—In the legislature of Louisiana a bill has been introduced for a magnificent scheme of internal improvement; namely, a railroad from New Orleans to Baton Rouge, St Francisville, and Clinton, thence eastwardly to the boundary line of Mississippi. This plan is recommended as part of a great route through Mississippi, Alabama, Georgia, North and South Carolina, and Virginia, to Washington city. The New Orleans and Nashville Railroad is proposed to extend from New Orleans to Nashville in Tennessee, from 480 to 500 miles in length.

In Tennessee, Kentucky, Ohio, Michigan, Indiana, and Illinois, extensive schemes of railroads have also been projected, which, when they are executed, will completely intersect these districts, and afford great facilities to internal intercourse.

Banking.

The substitution of paper-money for specie is a modern improvement of obvious advantage, but liable to peculiar risks. Dr Smith very clearly explains the benefits which arise from the judicious operations of banking, as well as its evils when it is carried to excess.[1] The great security against the abuse of paper-money, is its immediate convertibility into specie. It is a promise to pay on demand a certain amount of gold or silver. The punctual performance of this promise is the only sure guarantee of its value, which, where it is not performed, may vary to any amount, until the note degenerate into a mere piece of waste paper, as was the case in France during the progress of the revolution, from the inordinate issue of assignats. The great profit of a bank arises from the circulation of its notes, and its chief danger from the sudden return of those notes in exchange for specie. It is well known that no bank has a store of specie equal to the amount of its notes in circulation. The liabilities of the Bank of England have often been between twenty and thirty millions, while its stock of specie did not exceed one or two millions. Specie being, however, an expensive stock, a bank is tempted to carry on business with the lowest possible quantity; and as the disproportion between this fund and the liabilities increases, the hazard also increases of a run upon the bank, and a suspension of cash payments. Against this danger the American banks, though many of them conducted their business with success, and possessed ample funds, were not sufficiently guarded. In a time of panic, a bank, by the sudden influx of its notes, may be drained of its last guinea or dollar, as happened to the Bank of England in 1797. But when a bank has ample funds, every effort should be made, at whatever expense, and with the least possible delay, to provide specie, and to resume cash payments. In this country, though the Bank of England in 1797 might have been forced for a time to suspend its cash payments, yet the continuance of the suspension after the panic, and when the necessity had ceased, was a fatal error, and a most disgraceful fraud on the community, which was followed by the depreciation of the currency, and by great injustice and disorder. In 1805, the bank of Paris was exposed to a drain of specie to be remitted for payment of the French armies when they were in Germany, and was under a like necessity of suspending its cash payments; but when the pressure ceased, its payments were resumed early in 1806, after the conclusion of the peace of Presburg.

In 1836 the number of banks in America amounted to 636, in 1838 to 663, besides 166 branches, and several other banks from which no returns were received in reply to the application made. Including these, the whole may be estimated at between 800 and 900. Their capital was either subscribed by individuals, or it consisted of loans from the several states in which they were situated; and in many cases the state was a shareholder or sole proprietor of the bank. Where the state agreed to aid the bank with funds, or with its credit, bonds bearing interest, and payable in ten, twenty, or thirty, or any greater number of years that might be agreed upon, were issued to the amount of one or two millions of dollars, or to any greater or less amount, for which the borrowers gave a mortgage on real property to double the amount. The state bonds being disposed of in the market, the bank acquired the necessary funds for carrying on its business. In some cases banks have been established on the frail foundation of fictitious capital. The fourth part of its capital, for example, or out of 100,000 dollars, only 25,000 were really subscribed. For the residue the shareholders gave their bills, and pledged as a security the stock they had paid in; and thus the nominal capital was 100,000 dollars, but the real capital only one fourth. In one case the whole capital subscribed was next day given back under the name of a loan to the subscribers. Though such fraudulent transactions were not common, yet many of the banks possessed a slender foundation of capital, not amounting to 100,000 dollars, and in some cases not to above 60,000 or 30,000 dollars, and this often made up with paper promises. In most cases, however, the banks carried on a profitable business, and divided from five to eight and ten per cent.

No country has suffered so much from the mania for banking, or been so deluged with depreciated and worthless paper money, as the United States. There were 400 banks in existence in 1819, many of which had no adequate foun-tion of real capital. They were generally got up by knots of speculating tradesmen and lawyers, often without depositing a dollar beyond what was necessary to pay for paper and engraving. Even the respectable banks issued notes for a single dollar; but in the western country, where these establishments were on the worst footing, notes were issued for a half, a quarter, an eighth, and even a sixteenth of a dollar. An immense mass of paper money was thus put into circulation by these banks, which, when it fell into discredit, was followed by a degree of embarrassment and distress that had almost the character of a general bankruptcy. The paper bubbles burst, one after another, with extraordinary celerity, and involved multitudes in ruin. Of a hundred banks in Ohio, Kentucky, Tennessee, and Indiana, there were only two whose notes were received at the land-offices. In some of these states, acts were passed by the legislature, suspending legal proceedings to compel payment of debts. It may be imagined what an extraordinary derangement was produced in the state of property, when the circulating medium was reduced in three years (1815 to 1819) from 110 to forty-five millions of dollars.[1]

---

[1] Smith's Wealth of Nations, vol. i. p. 510.

Of the 663 banks which were established in America in 1838, the bank of the United States is by far the most important, from the extent of its capital, which amounts to 35,000,000 of dollars. It was incorporated in 1791, under the presidency of General Washington. The charter, which was for twenty years, expired in 1811; and from the fear that had in the mean time arisen, of this great national bank being converted into a political engine, it was not renewed. But owing to the disorder that arose at this time in the trade, and in the state of the currency, the consequence partly of the war with Great Britain, it was thought expedient to establish a new bank, with a charter for twenty years. General Jackson was decidedly opposed to this establishment; and in 1829, in his message to Congress, he expressed his opinion in the strongest terms. The senate and house of representatives entirely disapproved of the president's views, in which he however persevered; and though in 1832 an act was passed for renewing the charter of the bank, the president exercised his constitutional privilege of rejecting the act, it not being sanctioned by two thirds of the legislative bodies. In pursuance of his views, he in 1833 directed the government deposits to be removed from the federal bank to certain other banks, which he selected; though a committee of the house of representatives declared, on inquiry into its affairs, a balance in its favour of 43,058,143 dollars.[2] The contest between the executive and the monied interest was carried on with increasing acrimony; and such was the distrust of the banks by General Jackson and his friends, that they proposed to collect the public revenue entirely in specie, to be laid up in vaults under the charge of public officers. This question has created a great division in the American community, and has finally decided the late contest for the great office of president against Van Buren, an advocate of this system, and in favour of General Harrison.

But though General Jackson has carried too far his distrust of the banks, yet his measures, however mistaken, could not have occasioned the great calamity which soon after befell the credit and commerce of the United States. The cause was more deeply seated in the general condition of commerce, arising from the great extent to which credit was carried in Great Britain and in the United States, and the intense spirit of speculation thence arising, under the influence of which vast funds were lavished in ruinous adventures. A great increase had taken place in the importations, especially from Great Britain, which had risen from 108 millions, the amount in 1833, to 190 millions in 1836. A large debt was thus incurred to Great Britain, while vast sums, mostly in paper, to the amount, as estimated, of 125,000,000 of dollars, were expended on railroads, canals, banks, insurance and other companies, by which states, cities, corporations, and merchants, were involved in extensive engagements: wild tracts of government lands were purchased on speculation with paper to the estimated amount of about forty millions of dollars. The sales of these lands had increased from five millions of dollars in 1833, to twenty-five millions in 1836; extensive lots were besides purchased around the different cities, towns, and villages, with borrowed funds, and large sums were expended on rash improvements and on town buildings.[3] An immense superstructure was thus reared on a slender basis. There was a fair show of outward wealth and a false security, which continued until the unfortunate speculator was roused from his golden dreams by the commercial storm, and by a scene of ruin which was without a parallel in the history of commerce. The alarm began in Great Britain, where credit had been carried to a great excess. The bank contracting its credit to American houses, they in their turn called for payment of their American debts. At the same time Congress passed a bill, in June 1836, ordering that the surplus revenue of the United States, which had accumulated in the treasury, should, after reserving five millions of dollars, be deposited, by four quarterly instalments, with the several states. This sum amounted to 37,468,859 dollars. It had been lent out by the banks in which it was deposited, to the merchants of New York and other cities; and they being now suddenly called upon for payment, insisted on prompt payment from the merchants, at the time they were called upon to pay their European debts. The treasury order issued on 11th July 1836, in order to check the inordinate speculations in land, ordaining all payments at the land-offices to be made in specie, increased the pressure for money, and combined, with all the other causes, to hasten on the crisis for which the materials had been long prepared. The scarcity of money rapidly increased; those who in the riot of speculation had recklessly borrowed, were now called upon to pay; the golden dream had vanished, and they had no funds. A general panic now spread far and wide; the banks were assailed by demands for specie; and in May 1837 cash payments were universally suspended throughout the United States. This was followed by a general depreciation of the currency, which was more or less in proportion to its excess or its discredit; by a varying rate of exchange in consequence, for all remittances of money between the different states; by a universal panic, a fall in the price of all goods, and heavy sacrifices of property in order to procure funds. But these calamities, though they were aggravated, were not altogether occasioned by the failure of the banks. They were involved in the general ruin which arose from other causes, namely, the undue extension of credit, and the excess to which speculation was carried. Great commercial distress was also experienced from the same cause in Great Britain, where the Bank of England and the other banks continued to pay in specie.

To supply the want of change, notes were issued under the value of five dollars, though they had been prohibited by law; and it is mentioned in a Report on the State of New York, that "it was flooded with every species of depreciated paper, to the general annoyance and loss of the people at large." The suspension of cash payments is an expedient to which banks too readily resort in critical times. The Bank of England was extremely reluctant to part with this privilege, which it had so recklessly abused, and in which abuse it was, with little regard to justice, countenanced by those who then ruled the country. During the commercial pressure of 1814, all the banks south of New England suspended their cash payments; and they were countenanced in this proceeding by the merchants of New York and other places, though not by the government or congress, where other and wiser views prevailed. The merchants depending on the banks for accommodation, did not insist on a strict fulfilment of their engagements, lest it should compel them to contract their discounts, and to call in their debts, which would have added to the general distress. It is accordingly mentioned as a proof that public opinion was in favour of the banks, that in Massachusetts "suits for refusing specie were instituted against thirteen only of all the banks, and those suits are for trifling amounts."[1] The same feeling prevailed in all the other states. "The suspension," says the comptroller of the state of New York, in his Report, "was forced upon the New York banks by several powerful classes of persons, as a measure of relief," on the supposition that as soon as the banks were relieved from the obligation of redeeming their notes, they would discount more freely.[2] The attention of the Congress and of the legislatures of the different states was deeply aroused by the catastrophe which had befallen the banks, and the credit and commerce of the country; and acts were passed for regulating the issues, and the general management of their business. Commissioners were also appointed to inquire into the general condition of all the banks, to call for and examine their books or accounts; and they were empowered to bring the case of any bank under the consideration of a court of law, which might issue an injunction to its managers, setting aside and appointing receivers to take charge of its effects. Various acts were passed abolishing the issue of notes under the value of five dollars, and fixing a certain proportion between the circulation and the liabilities of the different banks. By an act passed in 1838, it is declared, that when any bank shall transfer to the comptroller of banks, an officer appointed in each state, a given amount of the public debt, he shall receive in return from the said comptroller an equal amount of circulating notes, which the said comptroller is required to cause to be printed and engraved, and to be countersigned, numbered, and registered in proper books, kept in his office, and to be delivered to any bank on the conditions above specified. According to this law, the circulating notes of banks are to be furnished by the state; and for the whole amount delivered, an equal amount of public stock, on which the bank receives interest, must be conveyed to the comptroller, as a security to the public for the payment of the notes.

[1] Report of the Secretary of the Treasury on the Currency, 1820. Flint's Letters from America, Nos. 16 and 17.

[2] See Mr Trotter's Observations on the Financial Position of the States of the North American Union, i. p. 15.

[3] See Statements in relation to the Condition of the State Banks, laid before Congress February 27, 1839, p. 404, Doc. No. 227. Report to the Missouri Assembly on the Currency, November 20, 1838.

The commissioners appointed to inquire into the condition of the banks made their reports, containing the returns of their capital, circulation, discounts, specie, deposits, &c.; besides just and clear views of the principles of paper currency, and of the necessity of specie payments to the maintenance of its value. From these reports, it appears that the American banks, with few exceptions, were solvent. They had ample funds for the discharge of their debts, though their stock of specie proved unequal to the ruinous drains to which they were exposed during the prevailing panic. A table is subjoined, containing a condensed statement of the capital, the circulation, deposits, debts due to other banks, other liabilities, together with the amount of specie in the different banks of the United States, on the 1st January 1839.

State or Territory.	Date.	No. of Banks.	No. of Branches.	Capital.	Specie.	Circulation.	Deposits.	Due to other Banks.	Other Liabilities.

* Incomplete. Maryland; no return from seven banks and two branches. Kentucky; returns embracing only loans and discounts, specie and circulation. No returns from Connecticut, New Jersey, Delaware, Mississippi, Illinois, Ohio, Michigan, and Florida.

---

[1] See Document No. 227, laid upon the Table of Congress February 27. 1839. Report of the Bank Commissioners of Massachusetts to the Governor of the Commonwealth of Massachusetts.

[2] "If the legal consequence of suspension," it is observed in the same document, "had been a contraction of bank issues, those who congregated in Wall Street, instead of coercing the banks to suspend, would have rallied round them to prevent a catastrophe so destructive to the honour and detrimental to the morals of the country, and so injurious to the credit of our great commercial emporium." Document No. 227. Extract from the Report of the Comptroller of the State of New York, p. 205.

From the above table it will be seen that the greatest nking establishment in America is the United States nk of Pennsylvania, with a capital of 35,000,000 of dol- s. There is another bank in this state, with a capital of 00,000 dollars, seven with capitals of between 1,000,000 d 2,500,000 dollars, eighteen with capitals from 224,000 752,000 dollars, and seventeen with capitals from 60,000 185,000 dollars.

The following is a statement of the banking capital in e state of New York.

	Capital in Dollars.
4	2,000,000
4	1,000,000 to 1,500,000
15	500,000 to 750,000
39	200,000 to 242,000
31	100,000 and under 200,000.

Of fifty-one banks in Maine, the largest capital is 300,000 llars; and there are only six that have a capital above 0,000 dollars. Of the twenty-eight banks in New Hamp- ire, there are only six that have a capital above 100,000 llars. Of eighteen banks in Vermont, the highest capital 300,000 dollars; and there are only three that have a pital above 100,000 dollars. In Massachusetts there are 0 banks.

	Capital in Dollars.
1	1,800,000
1	1,500,000
4	1,000,000
18 at or above	500,000
76 at or under	200,000, chiefly 100,000.

Of sixty-two banks in Rhode Island, there are fifteen of ich the capitals are between 200,000 and 500,000 dol- s, and there are twenty-nine under 100,000 dollars; e residue between 100,000 and 200,000 dollars. Of enty-three banks in Maryland, there are three whose pitals are from 2,000,000 dollars to 1,199,350; eleven th capitals from 250,000 dollars to 627,110. Of the re- lue, the capitals are from 50,000 to 175,000 dollars. In rginia there are five banks, with twenty branches, of ich the capitals of three amount to 6,337,000 dollars; ose of the other three are from 500,000 to 700,000 dol- s. In North Carolina there are three banks, with seven anches; amount of their several capitals, 1,500,000, 0,000, 225,000 dollars. In South Carolina there are even banks, with two branches; eight with capitals va- ing from 800,000 to 2,000,000 dollars. In Georgia there e twenty-one banks, with sixteen branches; six with pitals from two millions to one million of dollars; ten om 600,000 to 250,000 dollars. In Alabama, New Or- ans, Tennessee, Kentucky, Indiana, the capitals of the nks vary from 500,000 to 2,500,000 dollars. They are nerally above a million of dollars.

From the above statement, the capital of the American nks in many cases appears to be inconsiderable. Even is capital was not always paid up, but consisted in rt of the promissory notes or simple bonds of the share- lders, or for which the stock primarily paid in was pledged. aws were passed to guard against such abuses, but these ere evaded. Complaints were general against the banks the southern states, for entering into rash engagements assist, with permanent loans, railroads, canals, and other improvements; thus locking up the funds that should have been available for other purposes.[1] Among other expedients, the issue of bank post-bills was resorted to, by which debt was accumulated, and the evil day of payment was for a time delayed. The Scotish banks were formerly in the practice of issuing notes with what was called an optional clause, deferring payment for six months, which was wisely prohibited by act of parliament. The post-notes of the bank of the United States were gradually increased, as its affairs became involved, from 4,376,424, its amount in July 1838, to 8,994,443 dollars in November following; and other banks in the United States resorted to this and to other hazardous devices for raising money. It is not easy to determine the due proportion between the stock of specie and the liabilities of a bank. The bullion in the Bank of England has varied from one third and one fourth to one fifteenth of its circulation and other liabilities; and the American banks have generally retained in their coffers a proportion of bullion, amounting to a tenth, a seventh, a fifteenth, but sometimes not to above a 200th part, of the circulation and other liabilities. On a general average of all the American banks, the stock of specie amounted, in January 1839, to about forty-three millions of dollars, which was about one fourth of the circulation and other liabilities.

United States.

Though cash payments were generally resumed in 1838, a partial suspension again occurred at the close of the year 1839. The commerce of the country had by no means recovered from the recent shock; want of confidence still prevailed, and a scarcity of cash; and many were deeply involved in speculations of doubtful issue. The great bank of the United States in Pennsylvania, notwithstanding its large capital of thirty-five millions, was engaged in vast adventures, and was greatly embarrassed by the want of funds, to provide which it had been reduced to various shifts; among others, to the issue of post-notes, to the amount, as already stated, of above eight millions of dollars. No efforts however could any longer maintain its sinking credit; and its notes being refused by the bank of the United States in New York, as well as in Europe, its payments were finally suspended in October 1839, when the notes fell to a discount of ten per cent. It was proposed to resume cash payments in January 1841; but, according to the last accounts, a new panic had arisen in the United States, and it was doubted whether this resolution would be carried into effect, and even whether the assets of the bank would be found equal to its liabilities. All the southern banks suspended their cash payments as soon as they heard of the suspension of the Philadelphia bank; but those in New York honourably fulfilled, and still have continued to fulfil, their engagements, and to pay their notes on demand.

Finances.

The debt incurred by the United States at the close of the war with Great Britain in 1783 amounted, with arrears of interest in 1794, to 76,096,468 dollars, equal to L.17,121,704. It was reduced to 45,154,189 dollars in 1812. In 1815, after the conclusion of the war which began with Great Britain in 1812, the debt had increased to 158,713,049 dollars, and was reduced in 1820 to 91,225,560 dollars. In 1835 it was entirely redeemed; and in the following year a surplus had accumulated, which, with the reservations of five millions of dollars, was, in conformity with an act of Congress, distributed, as already stated, among the several states of the Union. This sum amounted to 37,468,859 dollars, and was to be paid in quarterly instalments. The last instalment was however deferred for a time, in consequence of the commercial embarrassments that occurred, and afterwards, by an act of Congress, indefinitely. The prudence, forethought, and economy of the American government in the management of its affairs is singularly contrasted with the reckless improvidence of the mother country, whose vast debt, increasing for more than a century, now swallows up for interest thirty millions a year, about two thirds of the whole national revenue. The following is the state of the American finances for 1837.

---

[1] The Select Committee of the State of Ohio observe: "This sudden expansion of the currency gave an unnatural impetus to the ordinary siness of the country, and opened the way to all the wild schemes of speculation that the imagination of the most enthusiastic fortune- nter could invent. The hitherto honest, industrious, and virtuous tiller of the soil, became a bold adventurer upon the broad sea of spe- ulation; the mechanic turned merchant; while the professional man, and the cautious dealer in dry goods and groceries, became proprietors cities, and the nominal owners of immense tracts of wild lands." See Papers laid before Congress, Document No. 227, p. 617. "No state the Union," says the Report of the Commissioners of the State of Mississippi, "is more deeply injured by an expanded currency than Mis- ssippi. The price of almost every article is nearly doubled, and in some instances trebled." In this state, the capital invested in banks had creased from 950,000 dollars, the capital of one bank, to 75,000,000 dollars in 1839.

		Dollars.
On the 1st of January 1837, the balance in the treasury, exclusive of trust funds and those belonging to the post-office, was		46,337,688·36
The receipts during that year, from all sources exclusive of the funds aforesaid, were		22,643,973·53
Viz.	Dollars.	
Customs	11,169,290·39	
Lands	6,776,236·52	
Miscellaneous	1,705,457·47	
Treasury notes	2,992,989·15	
These, with the balance last mentioned, constitute an aggregate of		68,981,661·89
The expenditures during the same year, exclusive of the trust funds, and those belonging to the post-office, were		31,815,409·91
Viz.		
Civil list, foreign intercourse, and miscellaneous	5,524,252·76	
Military service, including fortifications, Indian affairs, pensions, arming the militia, the Florida war, removal of the Cherokees and Creeks, improvement of rivers and harbours, constructing roads, and building armories and arsenals	19,417,274·44	
Naval service, including gradual improvement and exploring expedition	6,852,059·80	
Public debt	21,822·91	
This left in the treasury, on the 1st of January 1838, a balance of		37,166,251·98

We subjoin the following summary for the first three quarters of 1838.

Receipts or Means.	Dollars.
Balance on the 1st of January 1838	37,166,251·98
Receipts from customs	17,478,770·56
Receipts from lands	3,136,828·54
Miscellaneous	253,431·85
Treasury notes issued	12,716,820·86
Second and third bonds of United States Bank of Pennsylvania	4,542,102·22
	75,294,206·01

Expenditures.	Dollars.
Civil and miscellaneous, first three quarters	4,029,674·13
Military, first three quarters	15,731,323·62
Naval, first three quarters	4,325,563·21
Estimate of above expenditure for the fourth quarter	8,249,000·00
Public debt for the year	2,217·08
Redemption of treasury notes for the year	8,089,440·64
Balance on the 31st of December 1838	34,866,987·33
Total	75,294,206·01

Unavailable Funds in 1838.

Deposits with the states	28,101,644·97
Due from insolvent banks before 1837	1,100,000·00
Due from banks that suspended payment in 1837, and not payable till 1839	2,400,000·00
Part of money in the mint	500,000·00
Total	32,101,644·97

From balance on the 31st December 1838, being	34,866,987·33
Deduct total unavailable as above	32,101,644·97
Available balance remaining	2,765,342·36

Available balance in the treasury 1st January 1841 estimated at one million and a half of dollars.

The article entitled "deposits with the states" is the surplus revenue that was distributed among the several states. The United States are entirely free from the grievance of internal taxes, the public revenue being wholly derived from the customs and the sale of public lands. The post-office merely defrays its own expense.

Besides the public debt of the United States, several states of the Union have incurred debts for money laid out on railroads, canals, banking schemes, and public institutions of every description. In 1835 these debts were estimated at sixty millions of dollars; and they have since been greatly increased. Of the amount raised from 1835 to 1838, about forty millions of dollars were appropriated to the establishment of banks, and about sixty-eight millions to works of internal improvement. In many cases the funds have been judiciously laid out, and will make a suitable return;[1] but in other cases they will not yield a revenue sufficient for the repairs of the canals or railroads on which they have been expended, and for the payment of interest. When there are no adequate auxiliary funds, taxation must be resorted to for upholding the credit of the state. The Pennsylvania legislature has already agreed to the imposition of taxes, if no adequate funds accrue from other sources; and it is not doubted that all the other states will follow this example, and join in upholding the credit of the state bonds, which now form an article of traffic in the money markets of Europe. The following table, taken from the American Almanac for 1840, contains an account of the total amount of stock issued and authorized to be issued by each of the eighteen states where this mode of raising money has been resorted to. It is partly founded on the Annual Report for 1839, of the comptroller appointed under the general banking law passed in 1838, to inquire into the amount of the public debt in all the states, which was stated in that Report at 123,703,750 dollars, and partly on information derived from the state laws, which have been carefully examined, though it is probable that the aggregate amount of stock authorized by all the states is even greater than the amount stated in the table.

United States.

Army.

The free spirit of the Americans, and still more their parsimonious habits in public matters, make them averse to the existence of a large standing army. In this, as in some other things, they carry their opposition to the practice of European states too far. There is no danger to liberty in a free state from a standing army which is collected from the great body of the people, deeply imbued from the highest to the lowest rank with the spirit of freedom, and in all respects a most unfit instrument of tyrants. In Great Britain, the old constitutional jealousy of a standing army has been long exploded; and there is even less reason for jealousy on this subject in the democratical states of America; besides, that regular troops can be effectually opposed only by regular troops; and, in the present condition of the world, the state which denudes itself of efficient defensive weapons may be said to court disaster and disgrace. To supply the want of a small number of regular troops by masses of raw militia six times as numerous, who leave their homes under great personal and pecuniary sacrifices, is not economy, but the reverse; to say nothing of the certain defeat and disgrace to which such a force is subjected in its conflicts with a veteran enemy, and the humiliations which these produce to national feeling. After the close of the late war, the Congress, by act of 3d March 1815, fixed the strength of the regular army at 9980 men; but it was afterwards reduced, and its actual strength, as reported to Congress in March 1822, was,

Engineers	23
Four regiments of artillery	1977
Seven regiments of infantry	3367
Ordnance men	53
	5420

It has however been again increased, and the following is the general return, as stated by the adjutant-general, November 1838.

General staff	57
Medical department	83
Pay department	19
Purchasing department	3
Corps of engineers	43
Topographical engineers	36
Ordnance department	323
Two regiments of dragoons	1,498
Four regiments of artillery	3,020
Eight regiments of infantry	7,496
Total	12,539

The army is distributed at about fifty posts and places along the sea-coast and inland frontier. The pay of a colonel of infantry is seventy-five dollars (L.16. 10s.) per month, and six rations a day; of a captain, forty dollars and three rations; of a first lieutenant, thirty dollars and three rations; of a sergeant, eight dollars and one ration; of a private, five dollars and one ration. The Americans have a well-conducted military academy at West Point, on the Hudson, where 230 cadets, between the ages of fourteen and twenty-one, are instructed in the branches of knowledge necessary to form engineers. The period of service is five years, and the expense for each pupil is about 500 dollars per annum. But the chief military force of the United States is the militia, consisting properly of all the males between eighteen and forty-five, but always less or more deficient. A return made to Congress in February 1839 makes the number amount to 1,350,805. When called out to the field they have the same allowances as the regular army, and their period of service is limited to six months. The American militia are under the charge of the state governments. They generally if not universally elect their own officers, and are said to be very indifferently disciplined.[1]

Navy.

The naval branch of the service became extremely popular, from the exploits which it performed during the last war; and in 1816 Congress appropriated a million of dollars for eight years to increase the navy. The grant was afterwards reduced to 500,000 dollars, and continued till 1825. The following statement is given of the strength of the navy in August 1839.

		Guns.			Guns.
Ships of the line	3	74	Frigates	1	54
	7	80		14	44
	1	120		2	36
	11			17	
Sloops of war	20		Schooners	8	
Brigs	4		Steam ships (small)	2	

The expense of the naval service in 1837 was 6,854,059 dollars; and in the first three quarters of the year 1838 it was 4,325,563 dollars.

The navy is managed by a board of three commissioners and a secretary. A small tax of twenty cents per month is paid by all officers and seamen, both in the navy and merchant service, for the relief of sick and disabled mariners, part of whom are lodged in hospitals.

The great distinction of the American government is, that the first magistrate is chosen by the people, solely on account of his fitness for the office. In an hereditary monarchy, the same office descends from father to son, without regard to fitness. He who is in the line of succession obtains the throne, though he may be a minor or an infant, or however otherwise unfit for its great duties. This distinction of birth has been adopted in all the modern kingdoms of Europe, as the best security against rival claims, and the danger of a disputed succession. The illustrious historian of Rome observes, that of "all the various forms of government which have prevailed in the world, an hereditary monarchy seems to present the fairest scope for ridicule;" a nation being handed down like a drove of cattle to an infant son, and the "bravest warriors and wisest statesmen" approaching the royal cradle with bended knees and protestations of inviolable fidelity. Still, however, he adds, that though "satire and declamation may paint these obvious topics in the most dazzling colours, our serious thoughts will respect a useful prejudice, which establishes a rule of succession independent of the passions of mankind.... In the cool shade of retirement," he continues, "we may easily devise imaginary forms of government, in which the sceptre shall be constantly bestowed on the most worthy, by the free and incorrupt suffrage of the whole community. Experience overturns these airy fabrics, and teaches us that, in a large society, the election of a monarch can never devolve to the wisest or to the most numerous part of the people."[2] The truth of these eloquent observations, and their agreement with all previous experience, could not have been questioned at the time the historian wrote. The ancient democracies of Greece and Rome presented one continued scene of violence and disorder; they were bold but rude sketches of civil freedom, and they shine as meteors in the page of history; but the proper materials were wanting for the nice machinery of a popular government. The people were fierce and ignorant; they would not submit to the curb of the law; and those rude constitutions, loosely held together, perished amid the popular conflicts to which they gave rise. During the elective monarchy of Rome which cceeded, how often was the crown the prize of successful lence. Nor can the remark of the Roman historian, that o the firm establishment of this idea (namely, the hereary principle), we owe the peaceful succession and mild ministration of European monarchies," well be questioned, i the face of our own experience twice during the last cent y, of a disputed succession to the crown, and two civil wars i Great Britain.

---

[2] Gibbon's Decline and Fall of the Roman Empire, chap. vii.

opular election, however, if it lead to faction and disorder, ver fails to insure an able government, as the hereditary nciple is as certainly a source of weakness. When the ple have a free choice, they will always prefer merit to merit; capacity for service becomes in this manner a sport to honour and distinction, and ability is secured f the business of the state. The great men who ruled in eece and Rome almost invariably justified the choice of t people; their genius shone alike in war and policy, and t conquest of the world attested the wisdom of their ncils. Still, if the elective principle, an ever-living s rce though it be of energy, give rise to violence and diso er, it must be sacrificed to peace, the greatest of all blessi s. We cannot make use of an agency, however powerf which we cannot control. But in America they had n choice; they could not possibly have established a h editary government, and hence they were driven upon t critical experiment of a republic. That experiment h vever has succeeded. The great political principle of p ular election has been found to be compatible with a the great ends of government; and the election of a s reme ruler takes place every four years, without the least d urbance. The system therefore no longer answers to t description of the Roman historian; it is not an imagin y form of government, an airy fabric which experience o rthrows; it has been sanctioned by experience, and h been found to combine liberty and every civil right with g d order and peace, while it admits no principle that c impair the native vigour of a pure democracy.

he legislative power is vested in a Congress, consisting o Senate and a House of Representatives. The senate is c posed of two members from each state, chosen for six y rs, by the respective state legislatures, and the seats of o third are vacated every two years. A senator must b thirty years of age, an inhabitant of the state for which h is chosen, and he must have been a citizen of the Unite States for nine years. The members of the House of presentatives are chosen every second year, by the people, i he proportion of one for every 40,000 inhabitants, excludi the Indians, and two fifths of the people of colour. The e tors being the same as for the most numerous branch o the state legislature, the right of suffrage may be des bed as universal. A representative must be an inhabita of the state for which he is chosen, twenty-five years o ge, and he must have been seven years a citizen of the United States. No law can be passed without the concurrence of both houses. When that is obtained, it is presented to the president, who, if he approves, signs it; if not, he returns it, with his objections, for the reconsideration of Congress, and it cannot in that case become a law without the concurrence of two thirds of the members. The executive power is vested in a President, who is elected for four years, by a number of electors chosen for the purpose by the people, distinct from the senators and representatives whom each state sends to Congress, but equal to them in number. The president must be a native citizen of the United States, and not under thirty-five years of age. His salary is 25,000 dollars (L.5500) per annum.

The Congress has power to impose taxes and duties to pay the debts and provide for the defence of the republic; to borrow money; to regulate commerce; to establish uniform laws of bankruptcy and naturalization; to coin money, and fix the standard of weights and measures; to establish post-offices; to constitute tribunals; to declare war, raise and support an army and navy; to call out the militia, and to provide for organizing, arming, and disciplining it. The president is commander-in-chief of the army, navy, and the militia, when in active service. By and with the advice of the senate (two thirds concurring), he makes treaties, and nominates ambassadors, ministers, consuls, and judges.

The federal judiciary consists of the Supreme Court (formed of a chief judge and six associate judges), which sits at Washington, and a District Court in each state, in which one judge sits. The chief justice has 4000 dollars a year, an associate judge 3500, and a district judge from 800 to 2000. The supreme court, deriving its authority from the constitution, is not bound by the proceedings of the legislature farther than they are consistent with that charter. It has, accordingly, set aside several acts of the state legislatures, and even of Congress itself, on the ground that they contravened an express provision of the constitution, by annulling or impairing the validity of contracts. The laws of the United States are substantially the same with the laws of England, but differently modified in each state by causes springing out of the physical, moral, and political situation of the people.

There is no national church in the United States; each congregation pays its own minister, and each sect regulates its own concerns. Notwithstanding this, wherever the population is dense, the means of religious instruction are as ample as in any country in Europe. It is computed that there are above 8000 churches, or religious societies, of which about 3000 belong to the Baptists, 2000 to the Methodists, 1200 to the Congregationalists, 900 to the Presbyterians, 600 to the Episcopalians, and a small number to the Catholics, Dutch Lutherans, Universalists, and other sects.

UNIVERSAL, something that is common to many t gs; or it is one thing belonging to many or all things.

NIVERSALS. See METAPHYSICS.

UNIVERSE, a collective name, signifying the whole world; or the assemblage of heaven and earth, with all that they contain. See ASTRONOMY and GEOGRAPHY.

UNIVERSITIES.

UNIVERSITIES AND SCHOOLS.

Introduction.

The subject of this article may be conveniently divided into two parts; the first embracing Universities, and the second Schools. In treating of the former, it has been deemed the most satisfactory method to present a view of some of the oldest and most celebrated of the continental universities, and to subjoin a short account of the origin, progress, and present condition of those of Great Britain and Ireland. An opportunity will thus be afforded of viewing the higher education in its infancy, of observing the improvements which have at various times been introduced, and of forming an estimate of it after it has been in operation for nearly seven centuries. The space to which we are necessarily restricted prevents us from doing more than stating the principal facts: the subject, if treated in detail, would extend much beyond the limits within which it must be comprised in a work like this.

PART I.—UNIVERSITIES.

University (*Universitas*) has been defined "a universal school, in which are taught all branches of learning, or the four faculties of Theology, Law, Medicine, and the Arts, and in which degrees are conferred in these faculties." This we believe to be the meaning most commonly attached to the word university; and as it is palpably incorrect, it will be necessary for us to endeavour to point out its true signification. Like many other terms of extensive application, it has undergone various modifications of meaning, till its origin and primary use seem to have been utterly forgotten. By the nations of modern Europe, it has been applied to the highest seminaries of learning in their respective countries, whether these embraced "the whole circle of the sciences," or were limited to one or two faculties; and we accordingly find that the idea attached to the word varies in extent and comprehensiveness with the institution to which it is applied. Those who have formed their notion of the word merely from the English universities, commonly suppose that a university "necessarily means a collection and union of colleges; that it is a great corporation, embodying in one the smaller and subordinate collegiate bodies." The author of "A Reply to the Calumnies of the Edinburgh Review,"[1] asserts that "the university of Oxford is not a national foundation. It is a congeries of foundations, originating, some in royal munificence, but more in private piety and bounty. They are moulded, indeed, into one corporation; but each one of our twenty colleges is a corporation by itself." The inaccuracy of this opinion will appear from our account of that distinguished seminary. It is indeed sufficiently refuted by the fact, that many universities exist in which there are no colleges. This is the case with most of the German universities;[2] and in the Scotish universities there are no foundations which bear any resemblance to the English colleges. Edinburgh, though called a college, is merely a university, and has nothing in common with the English meaning of the term college; and the colleges at St Andrews, Glasgow, and Aberdeen, are corporations chiefly endowed for the principals and professors, and not for the students. Trinity College, Dublin, is a college with the privileges of a university, possessing however a munificent endowment for the provost, fellows, and scholars. It is important, besides, to bear in mind, that the universities of Oxford and Cambridge existed before a single college was endowed; and that the universities would continue to exist, with all their rights and privileges unimpaired, even if the property of all the colleges were confiscated, and their buildings levelled with the ground.[3] Another error, that universities were so called because they professed to teach *universal* learning, though maintained by men of such erudition as Mosheim,[4] Tiraboschi, and Dr Waddington,[5] and assented to by Mr Hallam,[6] is a mere quibble upon the word. The university of Paris, as well as Oxford and Cambridge, existed at first only in the faculty of arts;[7] Salerno and Montpellier contained the single faculty of medicine; and even Bologna was celebrated for 200 years as a school of law, before it contained any provision for lectures in theology. The teaching of the civil law was prohibited in Paris from 1220 till 1679; and other remarkable instances might easily be adduced, in which the study of particular faculties was forbidden in particular universities. It is true that most of the modern universities *embrace* the "whole circle of learning," as contained in the four faculties of the arts, theology, law, and physic; but this was not the case in the twelfth century, when the term *universities* was first applied to academical institutions.

University, in its proper and original meaning, denotes the whole members of an incorporated body of persons, teaching and learning one or more departments of knowledge. The word *universitas*, in the technical language of the civil law, was used to signify a plurality of persons associated for a continued purpose, and may be inadequately rendered by *society*, *company*, *corporation*. In the language of the middle ages, it was applied either loosely to any understood class of persons, or strictly to the members of a municipal incorporation, or the members of a *general study*.[8] In this application, it was used to denote either the whole body of teachers and learners, or the whole body of learners, or the whole body of teachers and learners divided either by faculty, or by country, or both together; its meaning being determined by the words with which it was connected. In the fourteenth century, the terms *magistrorum et scholarium*, and the like, which had hitherto been joined with *universitas*, were discontinued, and the word came to be used simply by itself, or in combination with *studium*, or *studium generale*;[9] as *universitas studii* Oxoniensis, Parisiensis, &c. In ecclesiastical language, the term was frequently applied to a number of churches united under the superintendence of one archdeacon, and to the college of canons in a cathedral. It is thus used of the body of ca-

[8] The oldest word for an unexclusive institution of higher education, was *studium* and *studium generale*; terms employed in the twelfth and thirteenth centuries, and retained in those which followed. The latter term, like *universitas*, did not mean originally that *all was taught*, but that *what was taught, was taught to all*; "generalitas ad *universitatem* non pertinet *scientiarum*, sed ad *publicam causam docendi*." Petri Gregorii Tholosani *De Republica* lib. xviii. c. i. sect. 87, as quoted in Edin. Rev. No. 121, p. 217.

[9] The substance of this account of the word university is taken from an elaborate article in the Edinburgh Review, No. 121, pp. 215, 216, and 217. To this article, and to two others apparently from the same pen, we have been largely indebted in compiling the following article.

Introduction.

ons of the church of Pisa, in a papal rescript of the ear 688;[1] and from such a body the transition was easy to e masters and scholars of a seminary of education.[2]

The period when universities were first established, can- ot be precisely ascertained. Previously to the age of harlemagne, Europe had sunk into the grossest barbarism, consequence of the migrations of the northern and east- n tribes, and the devastating wars which followed in their ain. This monarch merits the praise of having zealously deavoured to promote the cultivation of literature and ience throughout his vast empire. At his accession, we e assured that no means of education existed in his domi- ons; and in order to restore in some degree the spirit of ters, he was compelled to invite strangers from countries here learning was not so thoroughly extinguished.[3] Among ose who repaired to his court, were Alcuin of England, Cle- ent of Ireland, and Theodulf of Germany, men whose zeal s not inferior to that of the enlightened monarch. With help of these, he established schools in different cities of empire; and all the power and influence of the court were ployed in forwarding his patriotic endeavours to diffuse ne portion of education among his subjects.

By an imperial enactment, it was ordained that the hops should erect schools contiguous to their churches, ile the monks were enjoined to establish them in their nasteries;[4] and the imperial court, as it moved from ce to place, watched and rewarded the progress of science all the seminaries of the empire.[5] The impulse thus en to literature, though checked by the sloth and igno- ce of the monks and canons of the tenth century, was er altogether destroyed: the cathedral and monastic ools afforded the means of education, such as it was, to young men who were destined for the church; and ing the two succeeding centuries, "what learning there s, and what scientific men there were, were contained in, proceeded from their walls."[6] By degrees, the light science, which had been so long obscured, began to ne more brightly; teachers, whose genius and erudition bled them to overstep the narrow circle to which they themselves been restricted, arose in various places; wherever an Anselm or an Abelard opened his school, lectures were attended by crowds of admiring listeners.[7] e success of one teacher invited others to the same field abour, and the large numbers of scholars who frequent- the auditory of an admired expounder of some new or ourite question of scholastic logic or divinity, afforded ple room for the exertion of their talents and ingenuity. was in this manner that particular schools obtained a manent celebrity, and that those associations of teachers e formed, which were afterwards recognised by the civil ecclesiastical power, and dignified with the name of iversities.

The oldest universities of Europe," says Mr Malden,[8] rung up in the twelfth century, and were formed by the and enterprise of learned men, who undertook to de- r public instruction to all who were desirous of hearing n. The first teachers soon found assistants and rivals: lents resorted in great numbers to the sources of know- ge thus opened to them; and from this voluntary con- rse of teachers and learners, the schools arose, which e afterwards recognised as public bodies, and entitled universities,[9] and which served as models for those which, in later times, were founded and established by public authority. Some of the oldest universities had traditions of their foundation at a more remote period by royal or imperial authority, and these traditions might be nominally true; but as far as their real life, and power, and distinctive character are concerned, their origin was in fact spontaneous, and is to be ascribed to the general excitement which pervaded Europe in the twelfth century."

The oldest of the European universities were those of Paris and Bologna; the former for several centuries so celebrated as a school of theology as to be designated the "first school of the church," and the latter equally famous for the study of Roman jurisprudence. Of these two seminaries, as forming the models on which the other universities which subsequently sprung up in various parts of Europe were established, it will be necessary for us to give a somewhat detailed account. Omitting altogether the question of priority, we shall begin with the university of Paris, because we believe its claim to precedence on the ground of antiquity to be equally well founded with that of its rival, and because its form and constitution were in a great measure adopted by the founders of the two great English universities.

UNIVERSITY OF PARIS.

The commencement of this famous university is not recorded.[10] Tradition has assigned its origin to Charlemagne, and it is consequently referred to the beginning of the ninth century; but this opinion rests on no distinct evidence, and has been rejected by all recent writers who have examined the subject. Among the schools which the great emperor of the west established, it is doubtful whether we can reckon that of Paris; and though there are some traces of public instruction in that city about the end of the ninth century, it is not certain that we can assume it to be more ancient. For two hundred years more, it can only be said that some persons appear to have come to Paris for the purposes of study;[11] but the history of the school is very obscure, and, according to Mr Hallam, "it would be hard to prove an unbroken continuity, or at least a dependence and connexion of its professors." From the beginning of the twelfth century, Paris became the resort of learned men, who attached themselves in some degree to the existing schools, and infused new life into them by delivering public lectures on scholastic theology. One of these was William of Champeaux, who opened a school of logic in 1109, which is remarkable as the era from which alone the university can deduce the regular succession of its teachers.[12] This celebrated dialectitian, whose fame attracted crowds of pupils, was eclipsed by his disciple, afterwards his rival and adversary, Peter Abelard, to whose brilliant and hardy genius the university appears to be indebted for its rapid advancement as a seminary of school-divinity.[13] One of Abelard's pupils was Peter Lombard, afterwards archbishop of Paris, whose Liber Sententiarum, a digest of propositions extracted from the fathers, obtained the highest authority among the scholastic disputants. These and some other less distinguished preceptors first gave permanency to the future university.[14]

Paris.

The learning communicated in this ancient school, as in others of the same age, was comprised in two courses, called the *Trivium* and *Quadrivium*, terms employed from a very early age[1] to denote the seven liberal arts or sciences. The first course comprehended grammar, logic, and rhetoric; the second, music, arithmetic, geometry, and astronomy. It may easily be imagined, that in the tenth and eleventh centuries, the extent of learning comprehended under these seven heads was not very great; but small as it was, not many scholars proceeded beyond the Trivium, and the student who mastered both courses was looked upon as a person of profound erudition,

> Qui tria, qui septem, qui omne scibile novit.[2]

The university, as a corporate body, had as yet no existence; and the teachers, on whom its reputation rested, delivered their lectures in Paris and its neighbourhood, or wherever the prospect of success invited them. It consisted entirely of a congeries of schools, partly in connection with the churches and monasteries, and partly formed by the celebrity of literary adventurers. The number of these schools in the middle of the twelfth century was great;[3] encouragement produced masters, and able masters increased the number of scholars. The continually increasing number of teachers and students rendered it expedient to establish in the university some form of government to maintain the regularity and discipline necessary to its permanent success; and it accordingly appears to have been incorporated into a society toward the end of the twelfth century.[4] Matthew Paris informs us, that John de la Celle, elected abbot of St Albans in 1195, had studied at Paris, and had been elected into the company or body of established teachers.[5]

The antiquity of the different component parts of the university is involved in great uncertainty. The faculty of arts, which is acknowledged as the most ancient, appears to have existed at a very early period, and had assumed a regular form of self-government before the year 1169. In this year Henry II. of England offered to refer the adjustment of his dispute with Becket to the peers of France, the Gallican church, or the *provinces* (nations) of the school of Paris.[6] The head or rector of the university is named in an ordinance of Philip Augustus in 1206; the procurators of the nations (*procuratores nationum*) in 1218; the faculty of theology existed as a separate body in 1267; the faculties of the canon law and medicine in 1281; the rights of the chancellor of Nôtre Dame were exercised in 1169.[7] The oldest public documents extant which have reference to the Parisian school are two decrees of Pope Alexander III., the first in 1180, directed against the practice, which had been introduced by the chancellor, of exacting fees for licenses to teach; and the second, of nearly the same date, relieving Peter Comestor, who was then chancellor, from this prohibition.[8] The practice of receiving fees seems to have been revived; for when Innocent III. in 1215, by his legate Robert de Courçon, regulated the institutions of the university, he found it necessary to renew the ordinance that nothing should be given to the chancellor for granting licenses.[9] This ordinance, according to Savigny,[10] is remarkable as being the first in which the term university (*universitas*) is applied to the school of Paris; thereby implying the recognition and sanction of the university by the papal see, a sanction which was especially valuable, and even indispensable to its continued existence, when theology had become its leading study and its distinguishing characteristic.[11] Pope Nicholas IV., towards the end of the thirteenth century, conferred upon the university the additional privilege that the doctors who were there approved should everywhere have the power of teaching, lecturing, and directing schools (*docendi, legendi, regendi*), and should enjoy the privileges and rank of doctors throughout Christendom. Philip Augustus, by his ordinance of 1200,[12] granted to the university exemption from the ordinary tribunals, even from those of the church; prohibited the citizens, under the severest penalties, from molesting the students; and in the few cases in which the magistrates of the city were allowed to interfere, they were obliged to deliver over the culprit to his academical superiors. The person of the rector of the schools was declared to be sacred; and the provost of the city, immediately after his instalment, was required to wait on the masters and scholars in full assembly, and in their presence solemnly swear that he would carefully observe and fulfil the designs of the ordinance. This ceremony continued to be observed till 1592. The example of Philip was followed by the kings of France during the two succeeding centuries, by whom the privileges and immunities of the university were still further increased. By various regal enactments, the masters and scholars were exempted from all taxes imposed to defray the expenses of war, the king's court, family, representatives, or officers; from all customs, taxes, or personal burdens; were declared not liable to arrest, or to seizure or sequestration of goods; and were specially exempted from being summoned out of Paris in any legal process.[13] The popes were not less active in its support. By a letter of Innocent IV., it was provided that no one should pro-

---

[1] This division of the sciences is ascribed to St Augustin, and was certainly established early in the sixth century. Hallam's Mid. Ages, iii. 521. The enumeration answered to the seven cardinal virtues, seven deadly sins, seven sacraments, &c. and was comprehended in these memorial lines,—

> GRAM. loquitur; DIA. vera docet; RHET. verba colorat;
> MUS. canit; AR. numerat; GEO. ponderat; AST. colit astra.

But most of these sciences were scarcely taught at all. The arithmetic, for instance, of Cassiodorus or Capella is nothing but a few definitions mingled with superstitious absurdities about the virtues of certain numbers and figures. [12] This ordinance was published in consequence of a quarrel between the students and the citizens headed by their provost, in which some foreign students of eminence were killed. The masters presented their complaint to the king, demanded justice against the provost and his accomplices, and even threatened, with their scholars, to leave the city. The provost was condemned to perpetual imprisonment; and provision was made for the future protection and safety of the students. Bulæi Hist. Un. Par. iii. pp. 2 and 3.

Paris.

ulgate a sentence of excommunication, suspension, or in- rdict, against the university, or any of its members, with- it the special license of the apostolic see; and that, if pro- ulgated, it should be null and void.[1]

The university of Paris, being thus recognised by the pe, and encouraged by the fostering care of the kings of ance, soon became the most distinguished seminary of rning in Europe, and students resorted to it with an gerness for instruction which may well astonish those o reflect how little of what we now deem useful could imparted. A more systematic course of study was in- duced; theology and the arts ceased to be the only ob- ts of interest; medicine began to assume the form of a ence; and the canon law, under the special patronage of church, took its place as a new branch of jurisprudence. e study of the civil law was introduced in the twelfth tury, soon after its revival at Bologna, but was prohi- ed by Pope Honorius in 1220; a prohibition which In- cent IV. endeavoured to extend to the whole of France, gland, Scotland, and Hungary.[2] Some attempts were de to revive it under the authority of the parliament of ris in 1568; but the prohibition was renewed, and the iversity was not finally relieved from it till the year 1679.[3] e number of students in the twelfth century nearly alled that of the citizens, and included individuals from ry part of Christendom. At the death of Charles VII. 1453, it amounted to 25,000; and when Joseph Scaliger s a student, it had reached 30,000.[4]

Having thus traced the university of Paris from its ori- to its full establishment, we shall now give a short ana- is of its constitution in the thirteenth and fourteenth turies. The most ancient part of the university was faculty[5] of arts or philosophy, which is believed to have a special connection with the church of St Geneviève, probably originated in the school attached to that rch. The faculty was divided into four nations: 1. French nation, including the French, Italians, Span- ds, Greeks, &c.; 2. the nation of Picardy, which in- ded the students from the north-east of France, and the Netherlands; 3. the nation of Normandy, com- hending those from the west; 4. the English nation (ter 1430, called the German nation), which, besides students from the provinces subject to the English, as ctou, Guienne, &c., included the English, Scotish, Irish, es, Germans, &c. In these nations were enrolled the fessors and students from the respective districts, with- any distinction arising from the departments of learning which they were devoted.[6] This division, as we have ady seen, existed in 1169; and there is a concordat of four nations respecting the election of a rector in the r 1206, which proves that, at that time, their privileges e recognised and acted upon.[7] Each nation formed an independent body, had its own patron, church, place of meeting, academical buildings, great and small seal, &c., and managed exclusively its own affairs. At the head of each was a procurator, elected from their own number, whose duty it was to defend the rights and privileges of the nation, to convene and preside in its meetings, swear in new office-bearers and new members, and to see that all the acts and statutes were duly observed. The four procurators, with the rector, originally constituted the ordinary council of the university, in which its general government and legislation were vested. Their power extended even to the infliction of corporal punishment, some examples of which are mentioned as early as 1200, and in the fifteenth century they were not infrequent.[8] They had a common seal, and as a corporate body were represented by the rector.[9] Each nation was divided into provinces, and each province into dioceses. The names of the members of each province were enrolled in a register; and at their head was a dean, chosen by themselves. The deans formed the ordinary council of the procurator, and their assent was necessary in every undertaking of importance.[10]

In all the old universities, the chancellor was the fountain of honour, the officer by whose authority degrees were conferred; and this dignity brought along with it considerable power. Each bishop appointed a chancellor within his own diocese, whose office it was to preside in the bishop's court, and generally to maintain and exercise justice within the episcopal territory. After the full establishment of monasteries, the abbots claimed the same power, and created chancellors with similar authority. It belonged to the bishop and his chancellor to grant licenses to teach within his own diocese; and the same power was claimed and exercised by the abbot and his chancellor within the territory of the abbey.[11] When the university was placed in an episcopal city, the bishop of the diocese was very often the chancellor; and if not the bishop, some other ecclesiastical dignitary. The university of Paris being situate partly within the diocese of Paris, and partly within the abbey lands of St Geneviève, the power of granting license to students and masters was claimed by both. These chancellors were appointed, the one by his bishop, and the other by his abbot: the right of the latter extended to granting degrees in the arts only; that of the former to degrees in theology, law, and medicine. The chancellor of the church of St Geneviève was always the chancellor of the faculty of arts, though the bishop of Paris was the chancellor of the other three faculties, and was considered as the chancellor of the university at large. They chose their own deputies or vice-chancellors, appointed annual examiners of candidates for degrees, but had no power to interfere in the internal government of the university.[12]

M'Crie's Life of Melville, i. pp. 419, 420. To the cause of this prohibition it is unnecessary to advert. The popes were too quick- ted, and too much alive to their own interests, not to perceive that the authority delegated to the civil magistrate by the civil law militated nst their own absolute ecclesiastical claims.

M'Crie's Life of Melville, i. 18. Hallam's Mid. Ages, iii. 527.

The term *faculty*, in all the older universities, denoted the body of teachers or graduates, who, besides the privilege of lecturing on a ain department of knowledge, of examining and admitting candidates for degrees into their body, had also the right of making statutes, osing officers, employing a seal, and performing all the offices of a privileged corporation. In the French universities, the faculty con- d of the teachers alone, but in the Italian universities it was composed of the teachers and students together. Savigny, Geschichte, iii. 141. n. Rev. No. 121. p. 218.

They issued the decree which shut up the schools till redress was obtained from the king, for the insults injuries sustained by their body from the provost and citizens of Paris. According to Du Boulay, they formed the only governing body 1260. Hist. Un. Par. iii. 563.

Johnston's View of Education in France, p. 16.

The power thus vested in the heads of ecclesiastical establishments to which schools were attached, was sometimes used, through per- al motives, for the exclusion of fit and able teachers, as well as for the purpose of extorting a high price for license to teach. In the pon- ate of Alexander III. A. D. 1179, a Lateran council enacted, "that every competent person ought to be admitted to teach;" and in the owing year, the pope himself issued a decree, containing the following clause: "Ut quicunque viri idonei et literati voluerint regere stu- literarum, sine molestia et exactione qualibet scholas regere permittantur." Conringius, Dissert. iv. sect. 24.

Paris.

The rector appears to have been originally chosen by the four nations voting collectively; but the number of students belonging to the French nation gave it so decided a superiority, that the other three became dissatisfied, and at last revolting, elected another rector. To put an end to this difference, which threatened the prosperity of the university, and to restore unity and peace, delegates were appointed, by whose mediation it was agreed, and confirmed by the seals of the four nations, A. D. 1249, that the election should in future be vested in the four procurators, with certain provisions if they were not unanimous.[1] After the year 1280, he was chosen by electors specially appointed for the purpose. The rector was eligible from the faculty of arts only, and continued in office for three months, when he might be re-elected, or another chosen in his room. He presided in the general meetings of the university, took charge of the registers and public money, and administered generally the government of the university.[2] Within the city he took precedence, not only of all the officers and members of the university, but also of bishops, papal nuncios, and legates.[3]

Such was the constitution of the university of Paris till the middle of the thirteenth century. About this time the Dominican and Franciscan friars, supported by the pope and the bishop of Paris, succeeded in establishing the faculty of theology, which, after a strenuous opposition on the part of the heads of the university, was recognised in the year 1259.[4] Faculties of medicine and the canon law very soon modelled themselves upon that of theology.[5] The three faculties are separately mentioned in a deliberation which took place in the year 1277, and, four years after, were confirmed in all the rights and privileges of the university. At the head of each faculty was a dean, chosen in the same manner as the procurators of the nations, who presided in its meetings, and represented the body. From this period, therefore, the school of Paris, which had hitherto consisted of four bodies, was composed of seven, namely, of four nations and three faculties, represented respectively in the general council by four procurators and three deans. To the three new faculties belonged doctors only. The bachelors and scholars of theology, law, and medicine, were still included in the four nations of the faculty of arts. The general government of the university was vested in the council of seven, with the rector as president. The general assembly, comprehending all the masters, scholars, and officers (*omnes magistri, tam regentes, quam non-regentes*), was convened on great and interesting occasions only; and general meetings of all the regents were sometimes held for literary business, for framing statutes respecting discipline, privileges, and order. The meetings of faculties took cognizance each of its own members, in matters chiefly of a literary nature.[6]

The subordinate officers were, the syndic; the general procurator or agent of the university, who appears to have been an occasional rather than a permanent officer; and the greffier or recorder, who was the clerk and assessor. Each nation and faculty had its own clerk and assessor. There were also two classes of messengers, who were employed in transacting business of various kinds for the students.[7]

The university, as a corporation, was always very poor, and never possessed any public building, but was obliged to hold its meetings in the houses of the religious orders who were willing to grant the requisite accommodation.[8] The teachers originally delivered their lectures in such rooms as they could obtain for hire or otherwise. Afterwards, however, halls or schools for the use of their teachers were provided by the several faculties. Those of the faculty of arts and philosophy, which appear to have been very numerous, were in the *Rue de la Fouarre* (*vicus Stramineus*), and were apportioned among the nations of the faculty.[9]

The great concourse of students to the early universities, rendered it difficult for them to obtain lodgings, and gave rise to exorbitant demands on the part of the townsmen in whose houses they were forced to reside. To remedy this inconvenience, various expedients were adopted, but with inadequate effect. Frederick II. when he founded the university of Naples, fixed a *maximum* price for lodgings, and enacted that they should be let according to a joint valuation of two citizens and two scholars. A similar regulation was adopted at Bologna, and established about 1237, by Gregory IX. in the university of Paris.[10] The taxers were two masters of the university, and two burgesses elected with the consent of the masters. It was also provided that, when lodgings had once been hired, the student should not be disturbed in the possession of them, so long as he paid his rent, and conducted himself properly. Notwithstanding these regulations, the hardships to which the poorer students were exposed induced charitable individuals to provide houses, in which a certain number of indigent scholars might be accommodated with free lodgings during the progress of their studies. The example was first set by the religious orders, who established in several of the university towns *hostels* (*hospitia*) for those of their members who resorted thither, either as teachers or learners. Free board was soon added to free lodging, and in many cases small exhibitions or stipends to defray the necessary expenses of the scholars. For the sake of discipline, these foundations were placed under the superintendence of one or more graduates, who assisted and instructed their pupils, but only in subservience to the public lectures and exercises of the university. Such establishments were called *inns*, *hostels*, *halls*, or *colleges*; the last term being generally restricted to foundations which provided for the support of several graduates. These institutions, at first established on a small scale, led to the foundation of the colleges, which afterwards formed one of the most important and essential branches of the university.

Paris was the university in which collegiate establishments were first founded. Du Boulay[11] avers that colleges may be dated as far back as the university itself; and Crevier, according to Mr Hallam,[12] enumerates fifteen which were founded during the thirteenth century, besides one or two of a still earlier date. Savigny[13] considers the famous college of the Sorbonne, which was founded by Robert de Sorbonne, confessor of St Louis, in 1250, as the most ancient in Paris. Crevier probably included in his enumeration the *hospitia* established by the religious orders, which cannot properly be considered as colleges. During the fourteenth century many new colleges were founded, the most celebrated of which were those of Navarre and Du Plessis. The former, which is said sometimes to have contained seven hundred pupils, was founded by Joanna, queen of Philip the Fair, in 1304; and the latter by Geoffroi du Plessis, apostolical secretary to Philip V., in 1322.[14] The *Collegium Trilingue*, or Royal Trilingual College, was founded by Francis I. in 1529.[15]

The following account of the Parisian colleges is given by Mr Malden:[16] "The great colleges of Paris stood on a footing very different from the colleges of the English universities. They soon became appropriated to particular faculties, or to particular departments of a faculty; sometimes, but rarely, they included more than one faculty. Thus the theological faculty was collected at an early period in the college of the Sorbonne; and all its lectures and public disputations took place there, with the exception of two courses delivered in the college of Navarre. Regent masters were nominated by the faculties as lecturers in the colleges. These lecturers remained subject to their several faculties, and were liable to be controlled or removed by them. Consequently, attendance on their courses was considered as equivalent to attendance on the public courses delivered in the schools of the university. The colleges speedily began to admit within their walls scholars who were not supported by their foundations; and the college lectures were ultimately thrown open to the members of other colleges, and to those scholars of the university who belonged to no college at all. This took place in the course of the fifteenth century. The lectures in the public schools were thus almost entirely superseded, at least in the faculties of theology and arts; and the colleges became the instruments of the public instruction of the university. During the latter half of the fifteenth century, the great colleges of the faculty of arts, or, as they were called, the colleges 'de plein exercice,' amounted to eighteen; although by the middle of the seventeenth cenry they had fallen to ten. There were about eighty smaller colleges, which more than half still survived in the eighteenth century, which rovided their scholars with lodging and board, and sometimes with nall stipends, but taught them only the elements of philology, send- g them for all higher learning to the lecturers of the great colleges. he college of Navarre alone appears to have confined its instruction its own scholars. In this age of the university it became usual for l the scholars to belong to some college. Those students of the iversity who were not attached to any college, were known by the me of *martinets*. As they were less amenable to discipline than the dents of the colleges, the legislation of the university was directed ainst them; and at length it was made imperative on all scholars of e faculty of arts to be members of some college. The rule was not forced on students of the higher faculties."

[15] Previously to the erection of this college, there was no provision in the university for instructing young men in the learned languages. It was originally intended, as its name imports, for teaching Latin, Greek, and Hebrew; although it was some time before a teacher of Latin was appointed, owing to the opposition made by the members of the university, which led Erasmus, in one of his letters, to call them *bilingual* pedants. M'Crie's Life of Melville, i. pp. 19, 20.

[16] Origin of Universities, p. 34, 35, 36. The substance of the account is taken from the Edinburgh Review, No. 106, p. 400, &c., to which reference is made.

The origin of academical degrees, like many other points connected th the early history of universities, is involved in obscurity. Accord- g to Du Boulay, degrees were conferred, after a regular examina- n, from the very foundation of the university; while others assert it they were first introduced by Irnerius into the university of Bo- gna about the year 1150, and thence transferred to the Parisian iool.[1] That such distinctions existed at a very early period is un- estionable, but there is not sufficient evidence to justify us in believ- g that they were coeval with the earliest universities. The oldest grees were those in arts. The term *bachelor*,[2] used as the designa- n of the lowest degree in each faculty, which term is said to have been culiar to the feudal or military law of France, seems to warrant the erence that the whole system of academical honours has been bor- wed from the university of Paris. The terms master, doctor, were ginally synonymous, and were designations given in their common aning to persons engaged in teaching, and not titles conferred by thority after a prescribed course of study or a formal examination. process of time the name master was restricted to teachers of the eral arts, and the title of doctor was assumed by the teachers of ology, law, and medicine. The term professor, though less fre- ent in early times, had originally the same signification, and denoted erson who professed to teach a particular subject. In the English versities the Latin designation of a doctor of divinity still is "sanctæ ologiæ professor." Professor is now, in academical language, applied a salaried graduate, either actually employed in teaching, or at least ose duty it is to teach. When the masters of particular schools pted regulations, which were afterwards confirmed by public autho- , to prevent unqualified persons from assuming their office, the terms ster, doctor, professor, became titles indicating a certain rank, and veying certain powers in the scholastic body. They were still, how- r, confined to persons admitted by competent authority to the office eachers. When the titles of doctor and master were distinguished, l more especially when an initiatory stage was marked by the name *bachelor*, these successive designations were called *steps* or *degrees* adus).[3] Every graduate had an equal right of teaching publicly in university the subjects competent to his faculty, and to the rank is degree; and he even incurred an obligation to teach as the con- on on which the degree was granted. The bachelor or imperfect duate was bound to read, under a master or doctor of his faculty, a rse of lectures; and the master, doctor, or perfect graduate was, in manner, after his promotion, obliged to commence (*incipere*), and ontinue for a certain period publicly to teach (*regere*),[4] some at least he subjects pertaining to his faculty. The students were allowed hoose their regent, but were expected to attach themselves to some in particular. A period of *necessary regency*, different in different versities, was generally fixed, during which the graduates were nd to teach, and after which they might, if they chose, become *-regents*. The regents were allowed to exact from their pupils a ain regulated fee (*pastus, collectum*). The large number of gra- tes who were willing to devote themselves to teaching as a profession, to the shortening of the period of *necessary regency*, and enabled se to whom teaching was irksome to obtain a dispensation from its ies. The regents alone, except on rare and extraordinary occasions, e allowed to take part in the legislation and government of the versity. The regents were ultimately superseded by the institution alaried lecturers (*professores*), who delivered their instructions gra- ously. From the period of this innovation, which took place in 1719, the vigour of the university was gradually impaired. So long as the emoluments of the lecturers depended chiefly on the fees of their pupils, an honourable and useful competition was kept up; but the graduates, finding their pupils attracted by the gratuitous lectures of the endowed professors, ceased to teach, and the most powerful motive to exertion was thus withdrawn.

Paris.

The process of graduation was the following. After two years' study of grammar and philosophy, the scholar became a *determiner*; that is, he proposed himself, if *twelve* years of age[5] at least, to be taken on trials, in order, after further preparation, to his obtaining the degree of *bachelor*. The object of this proposal being made so early, was to subject the candidate to certain examinations, and to excite attention to his general conduct. In the middle of the fifteenth century, the course of study necessary for obtaining the degree of bachelor of arts was three years and a half. After passing the ordeal of the academical examiners, he was conducted by the rector to the chancellor, who crowned and blessed him. In consequence of passing as a bachelor, he wore a round cap, attended the holy mass, and became a candidate for the degree of master of arts. He was now required to devote an equal portion of time, three years and a half, to the study of philosophy, and, if found qualified, after frequent and severe examinations, was presented to the chancellor as worthy to receive license to teach the seven liberal arts. He was then invested with the *bonnet*, was publicly and solemnly declared a master of arts, and was at liberty to commence his career of teaching. But his magisterial character was not yet complete. He next offered himself a candidate for becoming a *socius*, or fellow of the masters in the university, an honour which was in the gift of the masters themselves, and by which he was admitted to the full enjoyment of their society, and of all their privileges.

To obtain the degree of doctor in divinity, it was necessary for the student to be twenty-five years of age when proposed, and to have studied philosophy for seven, or, if he belonged to a religious body, for six years. A further probation of nine years was requisite before he could attain that sacred degree. Two of these years were spent in the study of the Bible, and two in the study of the system of theology contained in the Book of Sentences. Sixteen years were thus spent at the university in order to become a doctor in divinity. The degree of doctor was conferred jointly by the chancellor and by the faculty, who admitted the candidate, with the solemnity of an oath, as a member of their body, and entitled to their privileges. The time necessary for acquiring the degree of doctor in law and medicine was shorter, and the rules were not so strictly observed. In each of these degrees certain fees were exigible.[6]

The students were required to wear a cap and gown of a particular form, varying with their standing or degrees in the university. The determiners wore a short black gown with a hood and sleeves, the bachelors a round cap and long gown of the best black cloth or silk, and the masters a gown which reached down to their heels.

The revenue of the university seems to have arisen at first entirely from the fees of the scholars, and from contributions which were occasionally levied from them. Some of the colleges, however, were richly endowed from the beginning, for the maintenance both of the scholars and the masters. Their weekly provision appears to have been very small. In the college of Navarre, the students of grammar received each *four sous* a week, the students of philosophy *six sous*, and the theologians *eight sous*. The teachers respectively received a double allowance.

Of the other early French universities, the most celebrated was that of Montpellier, which was constituted by a bull of Pope Nicholas IV. in 1289, and placed under the superintendence of the bishop of the diocese. Montpellier was at first only a school of medicine, but subsequently embraced also the other faculties. The university was divided into three nations, and was governed by a rector, elected annually, with the assistance of twelve counsellors, of whom four were selected from each nation.[7] The university of Toulouse was founded by Pope Gregory IX. in 1233, on the model of Paris, and was not much inferior to the pattern institution in success and celebrity. It early acquired fame as a school of law. The university of Orleans was established in 1307, and was occupied chiefly in the study of law. The students were at first divided into ten nations.

Bulæi Hist. Un. Par. ii. 674, &c. Dissert. vii.

The inferior degree of *bachelors* is said to have been first instituted by Gregory IX., whose pontificate continued from 1227 to 1241. They bably derived their name from *bacilla* (little staves), either because they were admitted by receiving a little wand, or because they adopted titles of the novices of the soldiery, who exercised with sticks, in order to learn to fight with arms. The word *bachelor* is commonly derived n *bas chevalier*, the humblest species of knight, in opposition to the knight banneret; but for this expression no authority has been pro- ed. *Bachelor* is a very old word, and is used in early French poetry for a young man, as *bachelette* is for a girl. Hallam's Middle Ages, iii. . Malden, p. 22, 23. Conringius, Dissert. iv. sect. 24. Itterus, cap. iv. sect. 25.

Malden, p. 111.

The technical term signifying to teach in the public schools, was *regere*; and the master of arts, or doctor of any faculty, upon his tion necessarily became a *regent*, that is, a teacher in the schools. In Paris, the masters who were desirous of exercising this privilege, tioned their faculty *pro regentia et scholis*; and schools, as they fell vacant, were granted to them by their nations, according to seniority. n. Rev. No. 106, p. 388. Malden, p. 112.

Bologna.

UNIVERSITY OF BOLOGNA.

The antiquity of this famous school is at least equal to that of Paris; and were it necessary to construe the word university in the strict sense of a legal incorporation, it might lay claim to still higher antiquity, inasmuch as its teachers obtained some important privileges before any such concession was made to those at Paris. It is alleged, and apparently on documentary evidence, that the emperor Theodosius established a school at Bologna in 433,[1] which, after it had fallen into decay, was restored by Charlemagne. It is probable that the school continued in existence from the period last mentioned; but there is no evidence that it was entitled to the name *university*, as that word was understood in the twelfth century. According to Mr Hallam,[2] there are a few vestiges of studies pursued in that city in the eleventh century; and there was also, in the same century, a school of the liberal arts at Ravenna, and a college of *judges* and *advocates*, who, besides administering and practising law, taught its principles in a public school. Masters and scholars are mentioned in documents of that age; and a certain individual, who was probably the head, is called *legis doctor*. A lawyer, named Pepo, who is designated by this appellation, delivered lectures on law about 1075, but without attracting much notice.[3]

We may safely assume that, like the other early universities, the progress of Bologna was gradual, and that its origin cannot be traced to any definite period of arbitrary establishment. The fame of successful teachers attracted pupils to their schools, and these, settling in the city, gradually claimed for themselves rights and privileges, which the citizens found it their interest to recognise, and which, in process of time, obtained the sanction of the emperor.

The university started suddenly into celebrity in the early part of the twelfth century, when Irnerius began to teach the Roman law. (See CIVIL LAW.) This great civilian is to be regarded, not only as the founder of the university of Bologna, but as the author of a great revolution in the jurisprudence of Europe. While engaged in teaching the liberal arts at Ravenna, he accepted an invitation from the civic authorities of Bologna, and opened a school in that city. He was employed as a lecturer in arts when copies of some of the books of the code of Justinian, which were beginning to excite attention, and to be circulated through Italy, reached Bologna.[4] Irnerius applied himself diligently to the study of them, and, after making himself master of their contents, undertook to expound them in the public schools. According to Conringius, he engaged in this course of lectures with the sanction of the republic of Bologna, and was rewarded for his labours at the public expense.[5] His zeal and energy collected large crowds of pupils, and gave an effectual impulse to the study of Roman law throughout Italy, while they raised the reputation of the lecturer to a pre-eminent height. The precise time at which Irnerius commenced his lectures has not been ascertained, nor are the events of the latter part of his life known. His name is mentioned in the records of public business and judicial proceedings between the years 1113 and 1118, when he appears to have relinquished his scholastic labours, and to have entered the service of the imperial court. By some he is supposed to have returned to his academical labours after the death of his patron Henry V. Sigonius, in his History of Bologna, fixes the time of his death in the year 1150.[6]

The study of law having thus revived, made surprising progress, and its fame spread rapidly from Italy over other parts of Europe. Students flocked from all parts to Bologna, and some eminent masters of that school repeated its lessons in distant countries.[7] Throughout this and several succeeding centuries, the schools of Bologna continued to be pre-eminent for legal learning. About the year 1220 they contained 10,000 students,[8] and in the middle of the fourteenth century the number had increased to 13,000.[9] "Not very long after the revival of the civil law, another subject of study, of much less intrinsic worth, was brought into public notice at Bologna. In the early ages of the church, the public letters of bishops were known by the name of decretals (*epistolæ decretales*)," the influence of which, at first feeble, kept pace with the increase of the papal power, till the decretals of the apostolic see came to be regarded as of equal authority with the canons of councils. In 1151, Gratian, a monk of St Felix in Bologna, published a collection of these epistles, which was known simply by the title of *Decretum;* a compilation which was immediately received with great favour, and was made the subject of public lectures in Bologna in the pontificate of Eugenius III., who died in the year 1153; and many scholars were attracted to the study of it.[10] (See CANON LAW.) Such was the origin of pontifical or canon law, a branch of jurisprudence which was long regarded by the church with peculiar favour. Of the school of arts and philosophy, in which, as we have already stated, the university originated, nothing is known during the twelfth century. Though obscured by the splendour of the rising school of law, it appears nevertheless to have maintained a certain degree of celebrity. The emperor Frederick II. deemed it worthy of his patronage, and about the year 1220 transmitted to it certain works of Aristotle and other philosophers, which he had caused to be translated into Latin, partly from the original Greek, and partly from Arabic versions. The interesting letter which accompanied the gift is quoted by Conringius.[11] This gift gave a new impulse to the study of philosophy.

The earliest historical document connected with the university is the charter of privileges granted by the emperor Frederick Barbarossa, at the diet of Roncaglia, in November 1158. In this authentic or rescript, which is entitled *Habita*, it is provided, first, that foreign scholars travelling to any seminary of learning should be allowed to pass without molestation; and that no obstruction should be offered to them, nor claim made upon them, under pretence of any public offence, or debt of the province or city to which they belonged; and, secondly, that all scholars, if any lawsuit were brought against them, should have the option of having it determined either by the *lord* or *master* under whom they studied, or by the bishop of the diocese.[12]

[11] Dissert. iii. sect. 20.

[12] "Si litem eis quispiam super aliquo negotio movere voluerit, hujus rei optione data scholaribus, eos coram domino, vel magistro suo, vel ipsius civitatis episcopo (quibus hanc jurisdictionem dedimus), conveniat." The edict is given by Conringius, Suppl. lxx., and is commented upon in his fifth Dissertation, and the annexed supplements. It is explained by Savigny, iii. pp. 153, 154.

y these singular privileges, which were afterwards the vy of other academical institutions, the students were empted from the ordinary tribunals, while the professors re invested with important powers. It is true that Bolgna is not expressly mentioned in the authentic; but that iwas intended for the benefit of Bolognese scholars is aprent, because Bologna was by much the most celebrated sool in the emperor's dominions, and probably the only e which was at that time frequented by foreign students. achers of law are specially mentioned, and Bologna was tn the only school of law; and the permission granted to t student to bring his cause before his "lord and mast," seems to assume that his judge was a legal character.[1] additional reason for applying the edict peculiarly to llogna, is found in the fact stated in Conringius,[2] that t principal professors in the university were at that time i attendance upon the emperor, having been invited by h to assist in deciding certain matters at issue between ln and the cities of Lombardy. It can scarcely be doubte therefore, that the edict was drawn up by them for the secial benefit of their own university, though the langage was purposely made general. The professors at first ierpreted its provisions as conferring upon them criminal a well as civil jurisdiction; but finding themselves unable t repress the violence of the students, they allowed the forr to remain in the hands of the magistrates of the city, a assumed to themselves only the power of determining cil suits.[3] This edict of Barbarossa is the earliest exaple of exemption or privilege granted to a university, a may be regarded as the source of the exclusive privies which were afterwards conferred upon collegiate insutions. The increasing power of the university excited t jealousy of the inhabitants of the city, and led to freqnt collisions, which, on more than one occasion, threated the existence of the school, but which generally ende in extending and strengthening its privileges. In the yr 1226, the emperor Frederick II. threatened to remove t school of law, but in the following year recalled his dree.[4]

Bologna was at first merely a school of law, and in this trefore the university consisted. The scholars were dived into two bodies, or *universities*, as they were called; t *citramontanes* and the *ultramontanes;* the former inding the Italians, and the latter, all foreigners. These we subdivided into nations; the citramontanes into seventn, and the ultramontanes into eighteen. Each nation h its presiding officer, called its *counsellor*, except the nion of the Germans, who had two, under the name of *curators*. At an early period the professors and scholars o arts and medicine endeavoured to form themselves into a parate university; but being opposed by the jurists and phibited by the city, they were compelled to unite themses with the scholars of law. A few years after, they rewed their efforts, and their right as a distinct univers was formally recognised by the city in 1316.[5] After t middle of the fourteenth century, a theological school w established by Innocent VI. It was placed under the lop of Bologna, as chancellor, and, like the theological fulty at Paris, consisted of doctors only, the scholars bei considered as belonging to the *artistæ*. Bologna had ts existed for more than two hundred years, as one of t most celebrated schools of learning, before theology fned a regular branch of study. Lectures in this faculty h been occasionally delivered, but the teachers were not ahorized or sanctioned by the university. From the year 1362, when the university of theology was founded, Bologna contained four universities; two of law; one of medicine and the arts, in which were included also the scholars of theology; and one of the doctors of theology. The two schools of law, however, formed together one whole, and are therefore frequently designated as one university.[6]

Bologna.

"There were also formed," says Mr Malden,[7] "in course of time, five colleges of doctors, which (with the exception of the theological college) were established upon quite a different principle. The theological college may have differed only in the number of its members from the university of theology. But there were two colleges of law, one of doctors of the civil law, the other of doctors of the canon law; and two separate colleges of doctors of philosophy and medicine. These colleges seem to have been corporations, in which a limited number of doctors of the several faculties were united, and monopolized the power of promotion and admission to degrees, to the exclusion of other doctors, who, according to the earlier constitution of the university, had an equal right to exercise it. They were confirmed, however, by the statutes of the year 1397. The first origin of the legal colleges runs back to the twelfth century; probably they were then open to all doctors. The legal colleges were each under a prior; how the others were governed, Savigny does not state. By these colleges or faculties, the candidates for degrees were examined. They had a building for their common use, in which they met, near the cathedral; because the public examinations were held in the cathedral, and degrees solemnly conferred there. Savigny warns his readers that these colleges of civil and canon law are not to be confounded with the *College of Doctors, Advocates, and Judges*, which was an institution of the city of Bologna for civic purposes. It may not be superfluous to warn the English reader not to confound these colleges, which were merely corporate faculties, with the English notion of the word college. There were some colleges in our sense of the word, which were restricted to the relief of really indigent scholars; but these foundations never had any weight or influence in any Italian university."

The constitution of the university was based on certain statutes which were promulgated at various times, and confirmed by Innocent IV. in 1253; but of these, and of the privileges conferred by them, our limited space will not permit us to give any account. The statutes were revised and corrected every twenty years, by eight scholars appointed for the purpose, and called *statuarii*. They were again confirmed in 1544, by the pope, who had then become sovereign of the city, and were made binding on the whole community.[8]

Savigny[9] mentions as the leading distinction between the universities of Paris and Bologna, from the earliest period, that in the former the masters or teachers constituted the corporation considered as a privileged body, to the exclusion of the scholars; while, in the latter, the students formed the university, and had the power of selecting from their own body the academical officers, whom the professors were bound to obey. At the head of the universities of law was the rector, who took precedence of all the other officers. The rector is first mentioned towards the end of the twelfth century, when only one was elected. For a long period two were chosen, one for each university; and finally one, which appears to have been the case in 1514, and which was established as the rule before 1552. He was chosen annually by the preceding rector, the counsellors of the na-

Bologna. tions, and a certain number of electors appointed by the university at large, and was taken from the different nations, according to a regular order of succession. The necessary qualifications for a rector were, that he should be twenty-five years of age, a *clericus*, not a member of any religious order, and should have studied law for at least five years, at his own cost. The powers of the rector were extensive. He possessed supreme authority over all members of the university, except those of the German nation, who were subject to their own procurators alone. His civil jurisdiction was not doubted when both parties belonged to the university, or when a citizen consented to bring before him a suit against a scholar; but when a suit against a scholar was brought before the magistrates of the city, the claim of the rector to hear it generally gave rise to a violent contest between the city and the university. Soon after the institution of the rectorate, an attempt was made by the city to abolish the office, or to render it subservient to the civic power; but the university succeeded in maintaining its privileges, which were ultimately confirmed by the authority of the pope. The criminal jurisdiction of the rector was limited generally to matters of academical discipline. He had the power of punishing both professors and scholars by fine and expulsion; and, in deciding more serious matters, he sometimes acted in conjunction with the magistrates of the city. In 1544, the pope confirmed by a bull his criminal jurisdiction when both parties belonged to the university, and when the offence was not capital. The rector was assisted by a council consisting of the counsellors of the nations.[1]

Chancellors. In Bologna, as in Paris, there were two Chancellors. Honorius III., whose pontificate extended from 1216 to 1227, when he regulated the *promotions* or collation of degrees in the school of law, placed them under the superintendence of the archdeacon of Bologna, whose consent, to prevent abuse, was rendered necessary. Savigny[2] appears to consider this as a personal authority vested in the archdeacon for the time; but it was retained by his successors, who assumed the title of chancellor, and exercised authority over all the faculties except the faculty of theology. The bishop of Bologna was constituted chancellor of the university of theologians, when this faculty was established by Innocent VI. in 1362. All honours emanated from the chancellors.

Other officers. Besides the rector and chancellors, the other officers of the university were: 1. The *counsellors* or representatives of the nations, who assisted the rector, and formed his council. Each nation elected one counsellor: the German nation was represented by two *procurators*, who were invested with judicial power over their own nation, independently of the rector. 2. The *syndic* or common agent of both universities, whose duty it was to defend their rights and privileges. He was elected annually from among the scholars, and was subject to the jurisdiction of the university at large. He received a salary of twelve *lire*, and latterly a third of all fines. 3. The *notary*, who was also common to both universities. 4. The *treasurer*, who was elected annually from the bankers of the city. 5. Two *bidelli*; one for each university.[3]

Degrees. The precise time when Degrees, properly so called, began to be conferred, cannot be ascertained; but perhaps we shall not much err in asserting that they were nearly coeval with the university itself. The earliest teachers were designated *dominus*, *magister*, *judex*, lord, master, judge; but these were names given to them as public lecturers, and were not titles of honour, carrying with them certain privileges, conferred by authority, and after examination.[4] *Magister* was probably applied indiscriminately to any teacher, while *dominus* and *judex* were designations assigned only to the teachers of the Roman law. There appears to be no reason to doubt that the terms soon came to be used synonymously. Savigny[5] states that, in the records of the university, Irnerius is styled *judex* or *causidicus*, but never *doctor*, and assigns the middle of the twelfth century as the date of this last title. The term doctor, here, as in Paris, originally signified merely a teacher, and implied nothing more than that the person bearing it had obtained a license to teach in that particular school. Some writers have asserted that it was borrowed from the theological school of Paris, while others have reversed the transmission, and allege that it was borrowed by the Parisians from the Italian seminary. The truth probably is, that it was given independently at both places. Savigny[6] supposes that it was in consequence of the privileges conferred on the masters and teachers by the edict of Frederick I., that they found it necessary to adopt measures to prevent the voluntary assumption of their office, and to establish a form of admission. If this supposition be admitted, it follows that degrees were conferred by public authority soon after 1158. The first doctors were no doubt those of the civil law, that being the branch of learning to which the Bolognese school was indebted for its early celebrity. At the close of the twelfth century we find doctors of the canon law, who soon obtained an equal rank with the civilians. In the thirteenth century, doctors of medicine, grammar, logic, philosophy, and the other arts, were added.[7] The title or dignity of doctor was at first conferred by the doctors themselves by *co-optation*, that is, they admitted the candidate into their body by common consent. This admission or promotion conveyed to him the right of lecturing in the school of Bologna, of exercising jurisdiction over his pupils, and of voting in the admission of future candidates. By a papal bull, the doctors of Bologna, like those of Paris, afterwards obtained the right of lecturing anywhere. The system of self-election having led to frequent abuse, by the admission of unworthy persons, Honorius III. in the early part of the thirteenth century, interposed his authority, and placed the promotions under the control of the archdeacon of Bologna.

The following extract presents a curious feature in academical history. "Originally," says Mr Malden,[8] "scholars were forbidden to marry into the families of Bolognese citizens, without the license of the rector. Exemptions from this prohibition were granted, which were at last extended to all the descendants of all doctors. By the terms of this exemption, it is manifest that the doctors of the university had become closely connected with the families of the citizens. This connection prepared the way for the gradual encroachments of municipal selfishness; and at last the principal chairs in the university were granted only to Bolognese citizens. But the actual doctors profited by the example, and went a step farther, and took an oath not to grant degrees to any but members of their own families. This outrageous monopoly began to produce its natural effects, in the ruin of the university; and commotions and struggles ensued between the years 1295 and 1304, which ended in compelling the doctors to admit all Bolognese equally to degrees; but the rank of doctor, at least in the two legal colleges or faculties, was still confined to citizens of Bologna."

Degrees were conferred in the civil law, or in the canon law, or in both. In the early age of the university single degrees were more common; in later times double degrees prevailed. Six years' previous study were necessary for the canonist, and eight for the civilian. If the student of the canon law had delivered a course of lectures, it was reckoned equal to a year's study; and in like manner the course of the civilian was shortened one or two years, by three or four years study of the canon law. The first step necessary for the candidate was to select a doctor who should present or recommend him to the archdeacon. He then underwent two examinations, the first of which (*examen*) was private, and the second (*conventus*) public. Previously to the first examination, two points of law were prescribed to him, which he was required to explain and defend, in presence of the chancellor and college of doctors. The doctor by whom he was presented alone examined him; the rest of the faculty having the power merely of asking questions and of stating objections, after making oath that no previous compact had been made with the candidate. The doctors were bound to treat the candidate *lovingly* as their own son, on pain of suspension from their functions for a year. The votes of the faculty were then taken, and if the examination was sustained, the candidate became a *licentiate*, that is, he obtained a license to present himself for public examination.[9]

The *conventus*, or public examination, by which the degree of doctor was acquired, took place in the cathedral, in presence of the university, when the licentiate read a thesis, and an exposition of a legal question, which was criticised, not by the doctors, but by the scholars. This was followed by an address from the archdeacon, or from a doctor deputed by him, in which the new graduate was solemnly proclaimed. He was then presented with the insignia of his rank, and had his place in the cathedral assigned to him.[10] It is probable that, in the earliest age of the university, this public examination by the scholars was the only one, and that the previous examination originated in an assumption of power by the doctors. The public examination frequently took place very soon after the private one, but sometimes a considerable interval was suffered to elapse, and thus the title of licentiate became a species of degree.

The candidate, before being received for examination, was required to swear, in presence of the rector, that he had studied for the period prescribed; before the private examination, that he had paid merely the requisite fees; and before the public examination, that he would promote the interest of the university and scholars, and if he remained in Bologna, would obey the rector, and comply with the statutes. At one time the commencing doctors took an oath to the magistrates of the city, that they would not lecture out of Bologna; but this oath was abolished in 1312, on the petition of the scholars, who purchased exemption from it with a sum of money.[11] It is a curious point in the tory of this university, that the female sex were admitted to its nours and offices. In early times degrees were conferred on learned men, who were even permitted to occupy professorial chairs. No-la d'Andrea read lectures on the canon law in the fourteenth cen-y; Laura Bassi was professor of physics in the eighteenth century; l Clotilde Tambroni, who was professor of Greek, died in 1817.

[10] Ibid. iii. pp. 195, 196.

[11] Savigny, iii. 198–202.

The expense of graduation was considerable. The fees for the vate examination amounted to sixty *lire;* those for the public ex-ination to eighty. Besides the fees, it was usual for the licentiate give clothes to many of those who took part in the solemn pro-sion; a custom which was found so oppressive that Pope Clement in 1311 ordained that an oath should be exacted from each candi-e that he would not expend more than 500 *lire.*[1]

All doctors, in right of their degree, had the power of lecturing or ching publicly; licentiates could not lecture without the permis-n of the rector. But even simple scholars, after five or six years of gent study, might obtain from the rector a license to teach, on ment of a fee proportioned to the importance of the branch of law which they proposed to lecture. The scholar who had lectured an entire treatise, or who had delivered a formal interpretation of oint of law, was considered to have earned his first degree, and k the name of Bachelor. When degrees became so common that doctors were not all necessarily obliged to teach, the jurisdiction r the scholars was confined to the *legentes*, or those who actually ured. All doctors who had at any time taught in the schools re-ied the right of voting in promotions.[2]

t is a remarkable feature in the constitution of the university of ogna, that the Professors at an early period received fixed salaries. the year 1279 the scholars made an agreement with a lecturer to ver a course of lectures for a certain specified sum; and in the fol-ing year they petitioned the city to pay a sum to the canonist sias for a course of lectures on the *Decretum*, and their petition was nted. In 1289 two professorships, one of the civil law and another he canon law, were established, with a fixed salary. The choice of professors rested with the scholars, who elected annually, sometimes electing the same person, and sometimes choosing another. The nber of endowed chairs continued to increase, so that in 1384 we l nineteen salaried lecturers in law, and twenty-three in arts. The ries of the professors of the civil law, which were the highest, ounted to 495 *lire* each. The salaries, which had hitherto been nted only for a year, now began to be considered permanent, and professors to regard themselves as public functionaries. In 1420 re were twenty-one teachers of law, of whom scarcely one is said have been elected by the university.[3] Besides the salaries given by state to the doctors, there were six endowed lectureships, to which olars only were eligible. The lecturers were appointed annually, seventy-six electors, and were equally divided between the Citra-ntane and Ultramontane scholars. Doctors, licentiates, and na-s of Bologna, were ineligible. This arrangement, according to igny, was acted upon in 1338; but in consequence of the tumult nding the election, it afterwards became customary for the univer-s to select twelve candidates, from whom were chosen by lot four urers on the civil law, and two on the decretals. According to Con-gius,[4] there were, in 1664, 126 professors in the school of Bologna, whom forty-nine belonged to the faculties of law; and the corpora- of the city was said to expend annually in their salaries nearly 00 crowns. The unsalaried professors received fees from their ils, and in the flourishing ages of the university many of them ac-ed great wealth.

uring the whole of the thirteenth century, the professors assembled r pupils in their own houses; in the fourteenth century public ools were founded, and were appropriated solely to the use of the tors. The bachelors were allowed the use of them twice a week he afternoon, if they were not occupied by a doctor. The courses ectures were begun on the 19th of October, and continued for a . The holidays amounted to about ninety, including two weeks aster and eleven days at Christmas.[5]

Bologna.

Modern Universities.

The university of Bologna, though fallen from its former glory, is still one of the first in Italy; and in several branches of study is inferior only to that of Pavia. The university contains the four faculties of theology, law, physic, and philosophy, and furnished in 1833 instruction in nine courses of education. 1. Elementary philosophy, which lasts two years, and consists of logic and metaphysics, the elements of algebra and geometry, physics and ethics. 2. Theological course, which lasts four years, and comprehends dogmatic theology, moral theology, lectures on the Scriptures, the Hebrew language, ecclesiastical history, and pulpit oratory. 3. Course of law, which continues four years: first year, institutions of the canon law, of the civil law, and of natural law; second year, institutions of public ecclesiastical law, and of criminal law, and text of the civil law; third year, institutions of public ecclesiastical law, text of the canon law, and text of the civil law, taught by a different professor from that of the second year; fourth year, text of the canon law, and text of the civil law, by both professors. 4. Notary course, obligatory for two years: first year, logic, metaphysics, and ethics; second year, canon and civil institutions. 5. Medical course; theory, four years, and two of practice. 6. Surgical course, three years, and two of practice. 7. Pharmaceutic course, two years; first year, chemistry and botany; second year, materia medica and pharmacy. 8. Veterinary course, two years; veterinary medicine, comparative anatomy, chemistry, botany, pharmacy, physiology, and materia medica. 9. Course of philosophy and mathematics, four years; the first two are nearly the same as in elementary philosophy; in the third and fourth years, fluxions, mechanics, hydraulics, optics, and astronomy.[6] Every student, before entering the university, must prove that he is possessed of a monthly income of twelve scudi or dollars, this being the smallest sum on which, it is believed, he can live respectably. The salaries of the professors amount to from 300 to 400 dollars, and the students pay no fees. The scholastic year begins on the 5th of September, and terminates on the 26th of June. Deducting the holidays, there are but 104 days of lectures in the year. The number of students is under 1000. The university library contains 150,000 volumes. There is also in the city another library, the gift of a clergyman, containing 83,000 volumes and 4000 MSS.

ENGLISH UNIVERSITIES.

Origin.

The English universities, like most of those which sprung up in remote times, were formed on the model of the university of Paris, and in the earlier period of their history bear a striking resemblance to the parent institution. Till 1836, England contained only two universities, those of Oxford and Cambridge. The origin of both is involved in doubt and obscurity, and it is probably impossible to decide at how early a period schools and places of general education existed in either. The question of the comparative antiquity of the two seminaries was agitated with great keenness in the seventeenth century, but the industry of the respective antiquaries has not thrown much light on the subject. Some of the more eager advocates of the remote antiquity of Oxford contend that it was a seminary of learning immediately after the destruction of Troy,[7] while the Cambridge antiquaries ascribe the origin of their university to one Cantaber, a Spaniard, by whom it was founded B. C. 375, and from whom it obtained the name Cantabrigia.[8] But though such speculations may amuse and interest the curious, they cannot be admitted as historical facts. The universities of London and Durham are of very recent origin.

Savigny, iii. 202, 205. Antony à Wood mentions several instances of the expense and magnificence which attended the early taking of higher degrees in England in the reigns of Henry III. and Edward I. About the year 1268, he says, when Alphonsus de Senis Siena, an Italian, studied at Oxford, one Bonifacius de Saluciis proceeded in the civil law, at whose inception there were such cere-nies and feasting, that the like for that faculty was scarce before known here. The abbot and convent of Oseney gave him the free use of r monastery on that occasion. He adds, that a still greater solemnity was performed some years after, at Gloucester College, by the Bene-ines, for one William de Brooke, a monk at St Peter's monastery at Gloucester, who took the degree of D. D. in 1298, being the first of order who had attained that dignity. He was accompanied by the abbot and whole convent of his own monastery, the abbots of West-ster, Reading, Abingdon, Evesham, and Malmesbury, numerous other priors and monks, and by a hundred noblemen and esquires on ses richly caparisoned. Wood, Hist. and Antiq. of the Univ. of Oxford, i. pp. 65, 66.

The *legentes* and *non-legentes* of Bologna correspond to the *regents* and *non-regents* of Paris, Oxford, and Cambridge, except that the former ns were applied only to doctors, while the latter were applied equally to doctors and masters.

UNIVERSITY OF OXFORD.

History.

The honour of founding this celebrated university is usually assigned to Alfred, who, according to John Rous, the antiquary of Warwick, who flourished in the fifteenth century, "built in this city three halls in the name of the Holy Trinity, for the doctors in grammar, philosophy, and divinity."[1] This opinion, though long maintained and strenuously supported, appears to be now generally abandoned.[2] The ablest antiquaries of modern times seem to be agreed that, although the university may be traced to very high antiquity, and far beyond the age of satisfactory records, the illustrious monarch whose name was formerly associated with it as its founder or restorer, had really no share whatever in its establishment.[3] It is at least certain that no document or well-authenticated history can be produced in which the name of Alfred appears as a benefactor of the university. Soon after the reign of Alfred, at least during the succeeding century, schools for the acquisition of learning appear to have been established in Oxford; but these were either of a private character, or were attached to the religious houses with which the town abounded. It is certain that Oxford was a place of study in the reign of Edward the Confessor (1041-1066);[4] but even at the time of the conquest it does not appear to have enjoyed any greater pre-eminence than that which naturally arose from the number of its monastic establishments, and from the circumstance of its having been, during the preceding century, a favourite residence of the English monarchs. Its schools might therefore be more numerous and better attended than those in other towns, and might possibly derive from royal favour some trifling privileges. When many of the secular scholars resided in one house, it got the name of a hall or hostel; and governors or principals were appointed over them, who superintended the discipline and civil affairs of the house. The schools were divided into grammar-schools, sophistry-schools, schools for arts, medicine or physic-schools, law-schools, divinity-schools, &c., names which, but for the literary remains of the early ages, would seem to indicate something like a defined system of education. No traces, however, of a regular plan can be discovered before the foundation of the first college in the middle of the thirteenth century.

In the beginning of the twelfth century, Oxford is again mentioned as a place of education. Robert Pulein, a theologian from Paris, expounded the holy Scriptures under the patronage of Henry I., and gave new life to the study of theology in England.[5] He continued his labours under the protection of Henry II. till he was called to Rome, and became chancellor of the apostolic see. In the reign of Stephen, Vacarius, a Lombard by birth, who had studied the civil law at Bologna, formed a school of Roman law at Oxford; and it is reasonable to suppose, as Mr Hallam observes, that a foreigner would not have chosen that city as the scene of his labours if he had not found a seminary of learning already established there. The introduction of this new science was opposed by the students of philosophy and theology, who prevailed upon the king to prohibit the lecturer from teaching, and to demand that all the books of law should be delivered up to him. This prohibition however was not carried into effect, since it appears from two decretals of Alexander III. in 1164 and 1170, that Vacarius remained in England in the reign of Henry II.; and there is evidence that the school subsisted for some time after his death. The difficulty and expense of obtaining copies of the original works on the Roman law induced Vacarius to compile for the use of his pupils an abridgment of the Pandects and Code which, according to Savigny,[6] was written in England about the year 1149. This opinion of Savigny is confirmed by Wood, who assigns 1149 as the date of the introduction of the civil law into Oxford, and refers to the same period, or to a time very little later, the introduction of the scholastic theology and the degree of doctor.[7] The study of the civil law, though honoured with the special patronage of the clergy, obtained but little favour from the laity of England. The circumstance of its being introduced from Italy, and recommended by ecclesiastical authority, disposed all laymen to look upon it with suspicion, while its rigid enactments accorded ill with the more liberal principles of the common law. The attention even of the clergy was soon diverted from it by the introduction of the canon law, which must have been taught at Oxford soon after the publication of Gratian's *Decretum*. The Benedictines of St Maur mention the existence of an eminent school of the canon law at Oxford about the end of the twelfth century, to which many students repaired from Paris.[8]

Even in that rude age, education seems not to have been entirely neglected by the English monarchs. Henry I. is said to have paid great attention to Oxford as a seminary of learning, and to have granted to the teachers and scholars, in their individual capacity, some important privileges. In the reigns of his two immediate successors learning declined, but it again revived under the encouragement of Richard I. New halls and schools were established under his patronage, and money was issued from his exchequer for their support. To so flourishing a condition indeed did he raise Oxford, that in the early part of the succeeding reign (A.D. 1201) it is said to have contained 3000 scholars.[9] The first reference to any public instrument where the term university (*universitas*) is applied to Oxford, is the 3d John (1201), an earlier date than any extant application of the word to Paris.[10] An unfortunate incident which occurred in 1209 interrupted this course of prosperity, and even threatened the destruction of the town as a seat of learning. A student, while engaged in some active exercise, accidentally killed a woman belonging to the town, and dreading the consequences, fled from justice. The mayor and burgesses immediately surrounded the hall to which the supposed murderer belonged; and failing to apprehend him, they seized three students entirely unconnected with the affair, and hanged them without proof or trial. The teachers and scholars, justly enraged at this barbarous act, unanimously quitted Oxford, and retired, some to Camidge, and others to Reading.[1] Not satisfied with this, they then applied to the pope, and obtained an interdict against the town, and against all persons who should settle in it for the purpose of teaching. The inhabitants finding themselves thus deserted by those on whom the prosperity of the town chiefly depended, waited upon the pope's legate, and obtained absolution, on conditions which induced the students to return to their former habitations. The king likewise bestowed on the students some new immunities, exempting them from any foreign judicature, and even granting them the power of taking cognisance in causes where one party was a scholar, or the servant of a scholar. (A. D. 1214.) From this year Meiners dates the commencement of the university properly so called.

---

[1] Du Boulay says that Alfred first entertained the intention of founding the university about the year 884, and invited masters from Paris to form and teach it; "ex hac nostra universitate Magistros evocavit ad eam componendam simul et regendam." Hist. Univ. par. i. 211 and 224, where the passage from John Rous is quoted. Henry's History of Great Britain, ii. 353.

[2] Mr Hallam, who, in his View of the Middle Ages (vol. iii. 524), states that, if the opinion of its foundation by Alfred cannot be maintained as a truth, it "contains no intrinsic marks of error," acknowledges in his last work (Introduction to the Literature of Europe, vol. i. p. 21, note †) that be had there given more credence to it than after further consideration he believed it entitled to. Bologna, as well as Paris, was full of English students about 1200. Meiners, ii. 428. Conringius, Dissert. iii. sect. 7.

[10] Dyer's Privileges of the University of Cambridge, i. 412, note.

Henry III. took advantage of a serious dispute which arose between the students and citizens of Paris in 1229, to advance the interests of Oxford, and invited the Parisian masters and scholars to settle there, promising them greater privileges than those which they had enjoyed in Paris.[2] A thousand accordingly accepted his invitation; but, presuming too much on the immunities which had been held out to them, they introduced a levity of manners, which gave rise to frequent tumults, and caused great alarm and disquiet in the town. The reign of this monarch is particularly memorable in the annals of the university. In the year 1244, he granted to it the first charter of privileges as a corporate body,[3] and in 1255 confirmed and extended the privileges which he had formerly conferred. Previously to this period, the scholars and students lodged and studied in halls rented from the townsmen; and this was one great source of the numerous quarrels which constantly took place between them. To remedy the evil, and also to encourage learning, several public-spirited individuals purchased or built large houses for the reception of the teachers and scholars, and thus set the example of appropriating funds for the support of those who had not the means of prosecuting their studies to advantage. Such was the origin of the English colleges, which at first modified, and have at length entirely superseded, the universities. Additional charters, some of fresh privileges, and others of general confirmation, were granted by Edward I. in 1275, Edward II. in 1315, Edward III. in 1327, and by succeeding kings. The English universities, it appears, solicited a recognition and renewal of their privileges at the beginning of every new reign. Their privileges now depend upon the act of the 13th Elizabeth, A. D. 1570, "concerning the Incorporations of the Universities of Oxford and Cambridge, and the Confirmation of the Charters, Liberties, and Privileges, granted to either of them." The *Corpus Statutorum*, or body of statutes, by which the university of Oxford is governed, was compiled, chiefly from existing statutes, by a committee appointed during the chancellorship of Archbishop Laud, and was solemnly ratified by the king, chancellor, and convocation, in 1636. These statutes, however modified by subsequent interpretations, additions, or restrictions, still determine the law and constitution of the university; and every member is bound by oath and subscription to their faithful observance.[4]

Various accounts are given of the number of students at Oxford in the reigns of the early Norman kings. Wood, in his Annals,[5] says, that in the time of Henry III. they amounted to 30,000; and even when Merton College was founded (1264), the number is said to have been 15,000. It may readily be granted that these statements are greatly exaggerated; still they seem to imply that the real number was very great.[6] Of the students, many were foreigners, from Paris and other places.

Oxford.

Confirmation.

The university of Oxford was confirmed by papal authority, and received from the see of Rome those privileges which it claimed the sole power of bestowing. It obtained a confirmation of its privileges from Innocent IV. in 1252; and from Boniface VIII. in 1296, the doctors and masters received permission to become lecturers and regents in any university in Christendom, without further examination.[7] Oxford is mentioned along with Paris, Bologna, and Salamanca, in the constitutions published by Clement V. after the council of Vienne, A. D. 1311. By these constitutions it was ordained that schools for Hebrew, Arabic, and Chaldee, should be erected in each of these *studia;* and that all prelates and ecclesiastical corporations in England, Wales, Scotland, and Ireland, should be taxed for the maintenance of professors of these languages at Oxford.[8] The interference of the Roman pontiff was frequently solicited on the part of the university, and his assumed authority submitted to in silence, especially by the less able of the English kings. It is clear, however, that by the more vigorous of the early monarchs the authority of the pope in matters relating to the universities was little regarded, or rather that it was utterly disclaimed. They considered the universities as not amenable to ecclesiastical superintendence, but took them under their own peculiar authority. Thus Henry III. on going to Gascony, appointed the archbishop of York and two others guardians of the university, to receive complaints during his absence, though, according to the canons, the government of it was vested in the bishop of Lincoln, the bishop of the diocese, and the archbishop of Canterbury, the metropolitan of the province.[9] Edward I. published a brief, which was confirmed by a parliament assembled at York, against the conduct of the preaching friars, although they were supported by papal bulls.[10] Edward III., in the fortieth year of his reign, in consequence of petitions from the universities of Oxford and Cambridge on the one hand, and from the friars of the four mendicant orders on the other, made an ordinance, with the assent of parliament, by which, after removing a prohibition imposed by the universities upon the admission of young scholars into these orders, it was enacted, "that all bulls and processes issuing from the court of Rome, and procured by the friars against either of the universities, or any person in them, should thenceforth be absolutely null and void; and the friars were forbidden to use or allege them."[11] The same king, nine years after, abrogated statutes made by the chancellor, proctors, and heads of the university, cited the official persons before him, and removed them for contumacy, although they pleaded in justification the pope's bulls.[12] Indeed the whole tenor of the privileges conferred by the various kings upon the universities may be considered as proving that, constitutionally, the power of the king and parliament was held to be supreme, and that the interference of the pontiff was submitted to only by sufferance.

Our space will not allow us to pursue in detail the history of this university. Beside the unfortunate incidents already alluded to, others occurred which gave a temporary check to its prosperity. In the reign of Edward I. a violent dispute arose between the university and the bishop of Lincoln, in whose diocese Oxford was then included, concerning the limits of the bishop's jurisdiction in university matters, which ultimately led to the total emancipation of the learned body from ecclesiastical authority, under the

sanction of a bull granted by Boniface in the year 1301.[1] The plague which broke out in 1349 nearly ruined the university, all the colleges and halls having been deserted and shut up during its prevalence. The reign of Richard II. is distinguished by the appearance at this university of John Wycliffe, who was the first warden of Canterbury College, and whose lectures on divinity loosened the shackles of popish thraldom, which Henry VIII. afterwards burst asunder, from motives very different from those which animated the first of the reformers. The succeeding reigns present little that is remarkable in the annals of the university, except the religious dissensions, which had nearly caused its dissolution. The reign of Henry VII. is entitled to the proud distinction of having fostered, with more than ordinary success, the revival of learning. Genuine scholarship had, during the preceding century, become exceedingly rare, and the Greek language had not only fallen into general disuse, but was affectedly held in contempt by a great body of the students, who formed themselves into an association, under the name of Trojans. So strong indeed was the prejudice against this language, that when Erasmus went to Oxford for the purpose of teaching it, several leading men in the university read lectures against him in the schools, and endeavoured to attach ridicule both to the man and to the knowledge which it was his object to disseminate. Through the vigorous efforts of Cardinal Wolsey, the Greek language was again received into estimation, and a taste for elegant literature was introduced. In 1518, the cardinal founded seven lectures for theology, the civil law, physic, philosophy, mathematics, Greek, and rhetoric, and appointed to all of them the men who were most distinguished for their abilities, and for their knowledge in these respective branches of learning. After the commencement of the reformation under Henry VIII., when the monastic orders were dissolved, and their property confiscated, and when the church in its unsettled state presented but few inducements to the study of theology, the number of scholars was very much reduced.[2] In 1546 only thirteen degrees were conferred; and in 1552, though the students who had their names on the books were a thousand and fifteen, yet the greater part were absent, and had in effect quitted the university.[3]

The changes which took place in the religion of the court during the reigns of Edward, Mary, and Elizabeth, affected considerably the prosperity of the university. The last-named sovereign granted to both universities the act of incorporation; and her successor, in 1603, conferred upon them the privilege of sending each two representatives to the national council. From the period of the revolution the university of Oxford has continued to flourish; its revenues have been increased; and the system of education now embraces the improvements which have been effected in almost every branch of science. The doctrines of the schools, it is true, received favour here for some time after they had been expelled from the northern universities; but they have now given way to the more rational views of experimental philosophy.

Colle
and H

One of the distinguishing peculiarities of the English universities, is the existence of collegiate establishments, some of which were founded at a very early period. We have already mentioned similar establishments in the university of Paris; but the English colleges, being more richly endowed, have to a much greater extent engrossed the powers and privileges of the universities. Of the existing colleges of Oxford, three, University College, Balliol College, and Merton College, were founded before the end of the thirteenth century, and in the following century the number was increased to seven. The motive which led to those foundations was the same which has been mentioned in treating of the university of Paris: to furnish the students with lodgings, to relieve the indigent from some portion of the expenses of their education, and to provide more effectually for the discipline of the university. In Oxford, the chancellor and his deputy combined the powers of the rector and the two chancellors in Paris; and the inspection and control, chiefly exercised in the latter, through the distribution of the scholars into nations,[4] under the government of rector, procurators, and deans, was in the former more especially accomplished by collecting the students into certain privileged houses, subject to a principal, who was responsible for the conduct of the members. But the number of the *colleges* in which provision was made for the support of the members was, for many centuries, small in comparison to the *halls* or *inns*, in which the students lived chiefly at their own expense, and were merely furnished with cheap and convenient lodgings. At the commencement of the fourteenth century, the number of halls was about *three hundred*, while the colleges amounted only to *three*. For the establishment of a hall, nothing more was necessary than that a few students, on a mutual agreement to live together, should hire a house, find surety for a year's rent, and choose for principal a graduate of respectable character. The chancellor or his deputy could not refuse to sanction the establishment, and to admit the principal to his office. The halls were in general held only on lease; but, by a privilege common to most universities, the rent was fixed every five years by sworn taxers, two masters and two citizens; and houses once occupied by students could not be resumed by the proprietors so long as the rent was punctually discharged. The halls were governed by peculiar statutes, and were liable to be visited and regulated by the university.[5] The causes which occasioned a diminution in the numbers of the scholars, diminished also the number of the halls, though that of the endowed colleges continued to increase. At the commencement of the fifteenth century, while the students were diminishing, the colleges had risen to *seven*. In the beginning of the sixteenth century, the number of halls had fallen to *fifty-five*, while the endowed colleges had increased to *twelve*. In 1546, the inhabited halls amounted only to *eight*; and in 1551, Wood remarks that "the ancient halls lay either waste, or were become the receptacles of poor religious people turned out of their cloisters."[6] As the students fell off, the rents of the halls were taxed at a lower rate; and they became at last of so little value to the proprietors that they were willing to dispose of them for a trifling sum. The old colleges thus extended their limits by easy purchase; and the new colleges, of which *six* were founded during the sixteenth century, were built on sites either obtained gratuitously or for an insignificant price.[1] Before this period the colleges had rarely admitted any students who were not on the foundation, and provided for by endowment; but they now began to receive independent members, and the diminution of the number of students in the university rendered it possible to receive nearly all of them. Since the beginning of the seventeenth century, only one college has been founded; and three of the eight surviving halls have been changed by endowment into colleges, but one of these is now extinct.[2]

---

[1] Ayliffe, i. 93. Neither Oxford nor Cambridge being the seat of a bishop, the scholars appear from the very first to have elected their chancellor, subject however in both cases to the approval of the diocesan. The advantages of this are very apparent. Instead of a distant superior exercising only an occasional and appellative jurisdiction, the chancellor was one of their body, and combined the offices which, in the continental universities, were divided between the chancellor and rector.

[2] Edin. Rev. No. 106, 410.

[3] Wood, as cited in Edin. Rev. No. 106, 410.

[4] "The division of the scholars into nations, which prevailed in all the universities of the continent, was unknown in England; probably because our insular situation prevented the influx of foreign students. There was a tendency at one time at Oxford to establish a similar distinction between the natives of the counties north and south of the Trent. For some time the proctors were chosen, one from each division; but the schism was healed. At Cambridge, by the composition between the scholars and the burgesses, in the fifty-fourth year of Henry III., conservators of the peace were to be elected annually at the beginning of the academical year, twenty-three in number (the original number of a jury), ten from the town, and thirteen from the university; and of these latter, five were to be English, three Scotch, two Welsh, and three Irish. This arrangement might easily have given rise to a division of the scholars into nations, each choosing its own conservators; but it was not attended by any such consequence." Malden on the Origin of Universities, p. 108.

[5] Wood, as cited in Edin. Rev. No. 106, 410.

[6] Edin. Rev. No. 106, 410, and authorities there cited.

In addition to the want of endowments, it may freely be admitted, that the more effectual superintendence and tuition which were supplied in the colleges, in consequence of the greater number of graduates who were members of them, contributed to the downfall of the halls. It remains only to mention the reason which, in the most crowded state of the university, has prevented one from being restored. Before the period of their downfall, the establishment of a hall was easy, and the chancellor was not at liberty to refuse his sanction. A piece of university legislation has effectually secured the monopoly to the colleges. The earl of Leicester, when chancellor of the university, about 1570, "through the absolute potency he had," obtained from the university the right of nominating the principals of all halls, and consequently in effect a *veto* upon the institution of any; and this right is now vested by statute in his successors. The heads of colleges being in reality the governing body, have since prevented any interference with their monopoly, by the establishment of a new hall.[3]

In the earliest period of the university, the scholars lodged, without domestic superintendence, in the houses of the citizens, as at Paris and Bologna, and attended such lectures as they chose. In the year 1231, it was ordained "that every clerk or scholar resident in Oxford must subject himself to the discipline and tuition of some master of the schools;" *i. e.* should enter himself as the pupil of one or other of the actual regents, while he was still left at liberty to select his own place of residence. At the commencement of the fifteenth century, however, it had become the established law, that all scholars should be members of some college, hall, or entry, under a responsible head. The scholars who frequented the lectures of the university, without attaching themselves to any college or hall, were called *Chamberdekyns*, as in Paris they were called *Martinets*; and frequent and decisive measures were adopted against them.[4] In the foreign universities, it was only the students of the faculty of arts who were obliged to place themselves under collegiate superintendence; but in the English universities the graduates and under-graduates of every faculty were equally required to be members of a privileged house. It is necessary however to observe, that entrance at a college or hall did not imply entrance under any particular tutor. "Young students, and many in those days were mere boys, were placed by their friends under the care of tutors; but these were private tutors, and the universities did not interfere with the private arrangement. It was not till the time when Leicester was chancellor, that the university undertook to regulate who might be tutors; and it was not till the chancellorship of Laud, that it was made necessary to enter under a tutor resident in the same college or hall with the pupil. Laud, therefore, may be regarded as the author of the system of college tuition."[5] In Oxford, according to its original constitution, as in all the older universities of the Parisian model, the business of instruction was not confided to a special body of privileged professors, but was conducted by the graduates at large. Every graduate had an equal right to teach, and even incurred the obligation of teaching publicly, for a certain period, the subjects of his faculty, as the condition on which he obtained his degree. Even the bachelor was obliged to give proof of his ability in teaching, by reading a short course of lectures under the superintendence of his faculty; and the doctor, after his promotion, immediately commenced (*incipiebat*) his duties as a public teacher (*regebat.*)[6] It was however necessary for the university to enforce this obligation of public teaching, during the term of *necessary regency*, only if a sufficient number of *voluntary regents* did not present themselves. When this was the case the period of *necessary regency* was shortened, and even a dispensation from actual teaching during its continuance commonly allowed.[7] The regents, whose duty as public lecturers was dispensed with, still retained their privileges as members of the governing body. The period of *necessary* regency was finally limited to one year; but the masters were allowed to remain *voluntary* regents (*regentes ad placitum*) for two years. A lecturer might continue to teach as a *voluntary regent*, after his term of *necessary* regency had expired; or he might resume his regency at pleasure. Now that the sole effect of regency is to entitle the master to become a member of the house of congregation, all continue regents for two years. All professors and public lecturers, the masters of the schools, and public examiners, are regents; and the name has been extended to all resident doctors, to the heads of houses, and to the deans of colleges.[8]

Oxford.

Professors.

The ancient system of instruction was gradually superseded by the appointment of salaried professors. The unsalaried regents in general found their schools deserted for the gratuitous instruction of the privileged lecturers; and though the right was expressly reserved to every doctor and master, of lecturing in the public schools on any subject pertaining to his faculty, its exercise was in a great measure abandoned.[9] "Some time," says Mr Malden,[10] "before the present statutes were digested under the authority of Archbishop Laud, there were, besides the professors of the superior faculties, ten professors or public readers of the seven arts and the three philosophies. They were appointed by the house of congregation, that is, by the regents; and attendance on their lectures was enforced by statute. In the time of Laud six of these enjoyed a permanent endowment; four were paid partly by the fees of their pupils, partly by fines levied on the regents whom they relieved from teaching. After the final collection of the statutes, A. D. 1636, by which the university is still nominally governed, we find eleven professors or readers in the faculty of arts. They lectured on grammar, rhetoric, and logic, the three branches of the ancient Trivium. Of the Quadrivium, geometry and astronomy had their professors endowed by the munificence of Sir Henry Savile, in 1619. Provision was made by royal endowment for teaching the Greek and Hebrew languages: and there were also professors of natural and of moral philosophy, of metaphysics, and of his-

Oxford.

tory. Music had its professor; but it was now separated from the faculty of arts. There were also two professors of divinity, a professor of civil law, a professor of medicine, and a prælector in anatomy, who ministered instruction in the higher faculties. The regius professorships of Greek, Hebrew, divinity, civil law, and medicine, were endowed by Henry VIII. in the years 1535 and 1540. The Margaret professorship of divinity was of older date."

Colleges.

Before proceeding to give an account of the system of education at present pursued in Oxford, it seems necessary for us to describe shortly the constitution of the various colleges of which both universities are composed. These may be regarded either as charitable foundations for the maintenance of a certain number of students and of resident graduates, or as houses of education in which young men desirous of obtaining degrees are lodged and placed under the superintendence of tutors. In the first point of view, each college is an independent corporation, wholly unconnected with the university, except in so far as its members are subject to the statutes; it is governed by its own laws, and is subject to the inspection of its own visitor, appointed in its charter of foundation.

Heads.

Each college consists of a Head, called by the various names of provost, master, rector, principal, or warden, of a body of fellows (*socii*), and generally of scholars also, besides various officers or servants. With the exception of one or two royal foundations, the heads of colleges are elected by the fellows, from their own number, possess superior authority in the discipline of the college considered as a place of education, and exercise an important office in the government of the university. In most colleges the heads are necessarily clergymen, and are allowed to marry. Their incomes vary so much as to render it impossible to make a definite estimate of them. They arise generally from the produce of a double fellowship, and from college livings attached to the office. The office is held for life.

Fellows.

The Fellows are the governing body of the college. The fellowships vary according to the extent of the colleges, and were either constituted by the original founder, or have been endowed by subsequent benefactors. In many colleges in both universities the fellows are necessarily graduates, either by statute, or by common usage; having passed the lowest degree, that of B. A., or student in the civil law. This rule, however, is subject to many exceptions. In New College, Oxford, which is an establishment connected with Winchester College, persons of the founder's kin are fellows on their first admission, and the others after a probation of two years. The classes of persons eligible to fellowships are also limited by the statutes of each college. At Cambridge, the limitation to particular schools, dioceses, and counties, is less common than at Oxford; but, on the other hand, it is the general practice in the former university for each college to confine the election of fellows to its own students. At Oxford, some of the followships in every college are open to the graduates of the whole university; but in some of these only is the election made on the principle of free competition, the others are disposed of by private interest and favour. In Downing College, Cambridge, graduates of both universities are eligible. Some few fellowships may be held by laymen, but in general they can be retained only by persons already in holy orders, or who are ordained within a specified time. Those who decline to take orders vacate their fellowships when the time allowed for the choice of a profession expires. Fellowships are of very unequal value. The best at Oxford are said to be worth, in good years, from L.600 to L.700, while many do not exceed L.100; and many at Cambridge fall far short of that sum.[1] They are paid out of the college revenues, which are for the most part received in corn-rents, and vary with the price of that commodity. The senior fellowships are the most lucrative; but all confer upon their holders the right to apartments in the college, and contain privileges as to commons or meals. The fellowships are tenable for life, unless the holder marries, or inherits estates which afford a larger revenue, or accepts one of the livings belonging to the college. In some colleges, graduates who have been elected to fellowships are required to pass a year of probation, during which they receive no income.

Scholars.

The Scholars are placed under different regulations, and enjoy different advantages, in the different colleges. They are on the foundation, but their connection with it is not so intimate as that of the fellows. They are always chosen from the under-graduates, and are often elected before they have commenced their residence at the university. At Oxford the scholars wear a different gown from the rest of the under-graduates, and in some colleges succeed by rotation to fellowships. In respect of discipline and education, they are on precisely the same footing as the independent students. The scholarships vary, in point of emolument, from L.100 or L.80 to L.20, or less, per annum, together with some advantages in the way of board.[2] In some colleges the students corresponding to the scholars bear different names, as the demies (*semicommunarii*) of Magdalen, Oxford.

Besides the scholars, there are in nearly all the colleges students named Exhibitioners, who have exhibitions, or annual pensions, given in some instances by the colleges, in others by free and endowed schools, to young men proceeding generally to the universities, or to particular colleges. Some of these are very valuable.

There are also several classes of inferior students, who are maintained either wholly or in part by the endowments. These poor students are generally required to perform some menial offices in the college, and bear various names. At Oxford they are named Servitors, Bible-clerks; and in Christ Church, Scholars; at Cambridge they are generally termed Sizars. In the latter university their position is more elevated than at Oxford.

The Tutors who conduct the education of the students are selected from the fellows. These, with the officers, as the Dean, who is the highest connected with education, the Bursar, &c., are sometimes the only resident fellows.

The university of Oxford is incorporated by the style of "The Chancellor, Masters, and Scholars of the University of Oxford." Its ancient charters were confirmed by the legislature in the 13th of Elizabeth; and its statutes, as has been already mentioned, were reduced into a digest in the chancellorship of Archbishop Laud. The principal officers of the university are the chancellor, the high steward, the vice-chancellor, two proctors, a public orator, a keeper of the archives, a registrar, public professors and lecturers, two curators of the theatre, two clerks of the market, the keeper of the Bodleian library, and the keeper of the Ashmolean Museum. The first five are invested with magisterial authority, and have the power of appointing deputies.

The highest officer in the university is the Chancellor, who is elected by the members of convocation, and holds his appointment for life. In the thirteenth century the chancellor was nominated by the regents and non-regents, and confirmed by the bishop of Lincoln, who was then the diocesan of Oxford. After the reign of Edward III. he was elected and confirmed by the regents and non-regents only. Till 1484, the office was held only for one, two, or three years, and was always conferred on a resident ecclesiastic until the time of Sir John Mason, in 1552, who was the first lay-chancellor. For nearly two hundred years it has been conferred on noblemen of distinction, who have been members of the university. The duties of the chancellor are, to defend its privileges, and to decide, either in person or by deputy, in all civil questions in which a member happens to be involved.

The Seneschallus or High Steward is appointed by the chancellor, and approved by convocation, and retains the office for life. The high steward assists the chancellor, vice-chancellor, and proctors in the execution of their respective duties, and defends the rights, customs, and liberties of the university. If required by the chancellor, he hears and determines capital causes, according to the laws of the land and the privileges of the university, when a scholar or privileged person is the party offending. He likewise holds the university court-leet, at the appointment of the chancellor or vice-chancellor, either by himself or deputy.

The Vice-Chancellor is in effect the supreme judicial and executive authority in the university. He is annually nominated by the chancellor, from the heads of colleges; but the office is, in practice, held by rotation for four years. The vice-chancellor appoints four deputies, from the heads of colleges, who perform his duties in the case of illness, or necessary absence from the university.

The Proctors, senior and junior, are two masters of arts, of at least four years standing, and not more than ten, who are chosen annually from the several colleges by turns, according to a peculiar cycle, fixed by the Caroline statutes of Charles I.[3] They are elected by the doctors and masters of arts; and after their election they nominate four masters of arts as deputies, and may depute their authority to a greater number if necessary. Their duties are, to preserve the peace of the university, in which they are assisted by their deputies, and have under their command the academical constabulary force; to repress disorders among the students, and to inflict summary academical punishments, as the imposition of tasks, confinement to college, &c. They have also an extensive police jurisdiction in the town. Their summary authority extends both to under-graduates and bachelors of arts.

---

[1] M'Culloch's Statistical Account of the British Empire, ii. 335.

[2] M'Culloch's Stat. Acc. ii. 336.

[3] Previously to the year 1629, the proctors were chosen by the common suffrages of the masters, and the canvass was generally attended with extreme tumult. To prevent the breach of discipline usual on such occasions, Charles I. converted these public elections into private ones; and that the office might be distributed through every college according to an arithmetical proportion, a cycle was drawn up by two celebrated mathematicians, which has since been followed.

The business of the university is transacted in two distinct assemblies termed "Houses," namely, the house of *Congregation* and the house of *Convocation*. The chancellor or vice-chancellor, or in his absence one of his four deputies, and the two proctors, or in their absence their respective deputies, preside in both houses, where their presence is indispensably requisite.

The House of Congregation consists wholly of regents, either *necessary* or *ad placitum*. Its business is principally confined to the passing of graces and dispensations, and to the granting of degrees. In the sole instance of supplications for graces, but in no other, every member of the house, in addition to his right of suffrage, has a suspending *negative* upon each grace for three times, as the grace is proposed in three distinct congregations; but previously to the fourth supplication, he is required to state privately to the vice-chancellor and proctors the ground and proof of his objection, which are subsequently submitted to the judgment of the house for approbation or rejection. All suffrages for or against graces and dispensations in congregation are to be whispered secretly into the ear of the proctor, by a majority of which, given in the word *placet* or *non-placet*, the fate of the measure is ultimately determined.

The House of Convocation, which is, with some limitations, composed of regents and non-regents alike, extends its power to all subjects connected with the credit, interest, and welfare of the university. In the exercise, however, of one particular branch of its privileges, the enacting of new or the explaining of old statutes, some restriction is prescribed. No proposition to explain or amend a royal or Caroline statute[1] can be received without royal permission. A proposition to enact any other new statute, or explain an old one, must be previously referred to the hebdomadal meeting, which, if it approve the proposition, draws up the terms in which it must be submitted to convocation; and thus, in fact, takes the initiative in every measure.

Oxford.

In both houses the chancellor or vice-chancellor singly, and the two proctors jointly, are officially invested with an absolute *negative* upon all proceedings, except in elections. When the negative of these officers is not interposed (an interposition nearly as rare as the royal veto in parliament), every question is decided by a majority. All elections, except for members of parliament, are made by a private scrutiny, in which the vice-chancellor presides, and the two proctors are scrutators. The members of parliament are chosen by the vice-chancellor, doctors, regent and non-regent masters, in convocation.

Hebdomadal Meeting.

The Hebdomadal Meeting consists of the vice-chancellor, proctors, and heads of houses, who meet every Monday, and at other times when convened by the vice-chancellor, to deliberate upon all matters relating to the preservation of the privileges and liberties of the university, and to inquire into and consult respecting the due observance of statutes and customs. All letters of the chancellor, in the case of dispensations, which are addressed to convocation, must, previously to a recital in the house, be sanctioned by their approbation.

Professorships.

The Professorships are of two kinds; those instituted by the crown, and those established by private endowment. The regius professors are appointed by the crown, the others according to the will of the founders. The professors as such have no direct concern with academical instruction or discipline. Attendance on their lectures is not, except in a few merely formal instances, necessary for the attainment either of university rank or college emolument; although, for the purpose of being admitted to holy orders, it is necessary for bachelors of arts to attend the lectures of the regius professor of divinity for a short time, unless they obtain a dispensation. The lectures of professors, therefore, are attended only by voluntary students.

The following is a list of the professorships, with the date of their foundation, and patronage.

Regius professorship of divinity.	1535	Crown.
— — — medicine.	1535	Crown.
— — — civil law.	1546	Crown.
— — — Greek.	1546 ?	Crown.
— — — Hebrew.	1546 ?	Crown.
Margaret professorship of divinity.	1497	Graduates of divinity.
Professorship of natural philosophy.	1618	Vice-chancellor, president of Magdalen, and warden of All Souls.
avilian professorship of geometry.	1619	Archbishop of Canterbury, lord chancellor, chancellor, &c.
avilian professorship of astronomy.	1619	Ditto ditto.
White's professorship of moral philosophy.	1621	Vice-chancellor, proctors, &c.
Cambden professorship of ancient history.	1622	Chancellor, masters, and scholars.
Professorship of music.	1626	Proctors.
Laudian professorship of Arabic.	1636	Presidents of St John's and Magdalen, wardens of New College, All Souls, and Merton.
Sherardian professorship of botany.	1728	College of Physicians.
Professorship of poetry.	1708	Members of convocation.[2]
Regius professorship of modern history and modern languages.	1724	Crown.
Professorship of Anglo-Saxon.	1795	Members of convocation.
Vinerian professorship of common law.	1758	Chancellor, masters, and scholars.
Clinical professorship.	1772	Members of convocation.
Lord Almoner's readership in Arabic.	1780	Lord almoner.
Aldrichian professorship of medicine.	1803	Members of convocation.
— — chemistry.	1803	Members of convocation.
Professorship of political economy.	1825	Chancellor, masters, and scholars.
Boden professorship of Sanscrit.	1832	Chancellor, masters, and scholars.
Lee's lectureship in anatomy.	1750	

Besides, there are three readerships, in experimental philosophy, mineralogy, and geology, established by a grant from the Crown in the years 1810, 1813, and 1818; the two last of which are at present held by Dr Buckland, the celebrated geologist.

The Public Orator is chosen by convocation, and must be at least either a bachelor in civil law, or master of arts. He is the secretary of the university, writes letters and addresses on public occasions, presents those on whom the honorary degree of master of arts is to be conferred, and delivers the annual Creweian oration alternately with the professor of poetry.

Every student admitted to the university is entered on the books of some college or hall. At the time of matriculation, he takes an oath to observe the statutes of the university, or submit to the penalties imposed for their violation, and subscribes his assent to the thirty-nine articles. If there is room for him in the college, he may commence residence immediately on matriculation; but this is not necessarily required of him till three or four terms have elapsed. Lodging in the town is in no case allowed to men under twelve terms standing. There is no difference in respect of priority of degree, admission, &c. between gentlemen commoners and commoners. The only privileges of the former consist in a particular dress, and in a separate table at the college dinner, with some trifling indulgences in particular colleges. In the case of noblemen, however, and the eldest sons of baronets and knights, the time for taking the first degree is shortened.

---

[1] The Caroline statutes, transmitted by Charles I., and confirmed by convocation, are those only which relate to the hebdomadal meeting, to the nomination of collectors in Lent, to the election of proctors, and to the procuratorial cycle.

[2] No professorship in the gift of convocation can be successively enjoyed by two persons of the same college.

Tuition. The student, on entering his college, is assigned to the superintendence of some one of the tutors. This, however, in most of the colleges, is little more than a form, as the tutors, who are generally three, four, or five in number, usually divide among themselves the discipline and instruction of the college; and the student is equally under the superintendence of all. The instructions of the tutors are directed solely to the preparation of the students for taking a degree, and consist of catechetical lectures, mixed with reading and discussion, on a portion of some classical or mathematical book in common use at the university examinations. Of these lectures, the students at first generally attend three or four daily. In the colleges which have a considerable number of under-graduates, divinity is usually taught by the dean, and mathematics by a separate tutor; but, with these exceptions, there is not much division of labour between the tutors in the same house. The subjects which form the academical education may be taken indifferently by any. Besides the class lectures, the tutors have from time to time interviews with their pupils separately, for the purpose of ascertaining more exactly their state of preparation for the public examination, consulting with them on the most effectual means of removing their peculiar difficulties, and arranging generally their plans of study. They also prescribe weekly exercises in composition, in Greek, Latin, and English. **Private Tutors.** In this department, however, the college tutors are not the sole labourers. Although recognised neither by the universities, nor by any particular college, a very numerous class has long existed both at Oxford and Cambridge, who, under the denomination of *Private Tutors*, superintend and assist the studies of individuals. Without interfering with the operation of the college lectures, they are occupied rather in securing for the student the best use of them, and, in the latter part of his course, in preparing him generally for his public examination. The fee of a *private* tutor at Oxford is L.50 a year; at Cambridge, where the academical year is somewhat shorter, L.40. The course of college lectures closes at the end of each term, with a formal examination of the students separately, by the head and tutors. This summing up of the business of the term is called, in the technical language of the place, *collections* or *terminals*, and occupies from two days to a week, according to the size of the college or hall.

According to the statutes, residence and attendance upon the university professors are requisite for all degrees. Students in arts are required to attend the lectures of the professors of that faculty during a period of four years to qualify for bachelor, and during seven to qualify for master; the particular branches for each year being also specified. The present practice, however, is very different; it has already been stated that the professors have been entirely superseded by the college tutors; and although the degrees emanate from them, they have no share whatever in communicating the knowledge which is requisite for their attainment. The degree of B. A. is the only one for which residence is indispensable.

Terms. The academical year is divided into four terms: 1. *Michaelmas*, which extends from the 10th of October to the 17th of December; 2. *Hilary*, from the 14th of January to the day before Palm Sunday; 3. *Easter*, from the tenth day after Easter Sunday to the day before Whitsunday; 4. *Trinity*, from the first Wednesday after Whitsunday to the Saturday after the act, which is always on the first Tuesday in July. The year of academical residence thus includes nearly seven months. The following is the time requisite for obtaining the different degrees.

Bachelor of Arts (B. A.); sixteen terms, for all except the sons and the eldest sons of the eldest sons of peers and peeresses in their own right, baronets, and the eldest sons of baronets and knights, who are admissible to their degree after having completed three years. Of the sixteen terms, however, twelve only are necessary in residence.

Master of Arts (M. A.); twelve terms after admission to a bachelor's degree. A master of arts becomes a regent after the act subsequent to his degree, and thereby obtains the privilege of voting in convocation.

Bachelor in the Civil Law (B. C. L.); three years, to be calculated from the regency. For those who do not pass through acts, twenty-eight terms are necessary, of which seventeen must be in residence.

Doctor in the Civil Law (D. C. L.); five years from the time at which the bachelor's degree was conferred; shortened to four for those who intend to practise at Doctors Commons.

Bachelor in Medicine (M. B.); twenty-eight terms after matriculation.

Doctor in Medicine (M. D.); three years after taking the bachelor's degree.

Bachelor in Divinity (B. D.); seven years from the regency.

Doctor in Divinity (D. D.); four years after taking the bachelor's degree.

Degrees in Music are merely honorary; but the performance of some piece of music is required by way of exercise.

Candidates for the degree of bachelor of arts are required in the sixth or eighth term, unless dispensation be obtained for a later period, to undergo the preliminary examination called *responsions*; that is, to answer questions publicly proposed by the masters of the schools.[1] This exercise consists of an examination in the Greek and Latin languages, chiefly with a view to their grammatical construction; and in the rudiments of logic, or a portion of Euclid's Elements of Geometry. This examination is technically called the "little go;" and to have failed three times in passing it (or, in the Oxford phraseology, to have been "plucked"[2] three times) is generally considered a disqualification from further pursuing the studies of the university.

The public examinations are held twice a year, viz. in Michaelmas and Easter terms. The public examination comprises, 1. The rudiments of religion, under which head is required a competent knowledge of the gospels in the original Greek; of the history of the Old and New Testament; of the thirty-nine articles of the church of England; and of the evidences of religion, natural and revealed. 2. The *Literæ humaniores*; under which head is comprised a sufficient acquaintance with the Greek and Latin languages, and ancient history; with rhetoric and poetry; with moral and political science, as derived from the Greek and Roman writers, and illustrated, if necessary, from modern authors; with logic, which is indispensably required from all candidates for the first, second, or third classes; and with Latin and English composition. 3. The elements of the mathematical and physical sciences.

With regard to the examination in some parts of the literæ humaniores, and in the elements of the mathematical sciences and of physics, the examiners have a discretionary power; a knowledge of the latter branches not being indispensable. They are however bound to examine all candidates in at least three Greek and Latin classical writers, in logic or the first four books of Euclid, and to ascertain their proficiency in translating from English into Latin. With respect to the rudiments of religion, they possess no discretionary power; and any failure in this part of the examination must preclude the candidate from his degree, without regard to any other attainments.

Such are the acquirements necessary to enable a student to obtain a degree. Those who aspire to "honours" are required to embrace a wider field, and are subjected to a more strict examination, which lasts three or four days. The candidate for honours may attain them either in classical literature and moral philosophy (*in literis humanioribus*), or in mathematics (*in disciplinis mathematicis et physicis*), or in both. As a preliminary condition, he must however satisfy the examiners of his proficiency in divinity, though he is not in general subjected to a severer trial than those who merely present themselves for a common degree. The candidate for mathematical honours must, in the first instance, "pass" in classics. The candidate for classical honours is allowed to choose his own books for examination, which generally amount to fourteen or sixteen. Among those most commonly chosen are, Herodotus, Thucydides, Livy, Sophocles, Horace, Virgil, and Aristotle's Rhetoric and Ethics. To these some add, according to their inclination, Aristotle's Poetics, Lucretius, or a scientific dialogue of Cicero, part of Homer or Pindar, or Æschylus, some plays of Aristophanes; and some few take a selection from the orators, or from Polybius or Tacitus. The necessary extent of knowledge in mathematics and physics, though inferior to that which is required at Cambridge, embraces geometry, algebra, Newton's Principia, mechanics, hydrostatics, astronomy, and optics. The examinations are conducted principally by means of printed papers.

When the examinations are concluded, the names of those who have honourably distinguished themselves, by passing a good examination in a wider range than that necessary for a mere degree, are distributed in alphabetical order into four classes, under the two divisions of *literæ humaniores* and *disciplinæ mathematicæ et* ford. hysicæ. A fifth class gives the *number*, without mentioning the ames, of those who, though they have obtained their *testimonium*, re not deemed worthy of any honourable distinction. Printed co-ies of the schedule containing these classes are sent to the chancel-or, vice-chancellor, the heads of houses, the proctors, and to the efectory and common room of each college and hall. The exami-ations for fellowships, scholarships, &c., are conducted in the ame manner as those for honours, with this exception, that ma-hematical knowledge generally goes for little in college competi-ions for fellowships, unless the college should chance to be in vant of a tutor in that department.

---

[1] There are three masters of the schools, who must have been admitted regents in arts, one of whom is nominated in convocation by the vice-chancellor, and one by each of the proctors, annually, on the first day of Trinity term. The presence of two masters is necessary at the responsions.

[2] This phrase had its origin in an ancient custom, by which any one who objected to a degree about to be conferred in congregation, notified his dissent by plucking the sleeve of the proctor's gown.

iners The examiners for degrees are, seven masters of arts, four in lassics and three in mathematics, who are appointed by the vice-hancellor and proctors, subject to the approval of congregation nd convocation.

Degrees in the civil law and medicine are merely nominal ho-ours, and are not conferred on special examination; but they can nly be obtained by those who have passed a bachelor's examina-ion in arts. For degrees in divinity, attendance on divinity lec-res is requisite. There are, besides, disputations and exercises en-ined by statute for all the higher degrees, the performance of hich is little more than nominal.

Oxford. Expenses.

The expenses of an under-graduate vary so materially, according to the taste and habits of each individual, that it is impossible to present any satisfactory statement of them. The whole expenditure, exclusive of a private tutor's fee, an expense which is incurred only by those who are preparing for honours, of such commoners as live on the most economical scale, has been estimated from L.200 to L.250 a year.[1] The ordinary college account, including university and college fees of all kinds, boarding, lodging, washing, coals, and servants, varies from L.60 to L.100 at different colleges, for commoners, and from L.30 to L.40 more for gentlemen commoners. The students dine together in the college hall, sitting at different tables according to their ranks and degrees. Their remaining meals are taken in their own rooms. The university, as a corporation, possesses very little property except the libraries and public buildings; and of these the most important have been raised either by the munificence of individuals or by public subscription. The estates which have been bequeathed to it have been appropriated either to the endowment of certain professorships, or to the augmentation of the libraries.

For the Bodleian Library, Clarendon Press, &c. see LIBRARIES and OXFORD.

The following are the existing Colleges and Halls at Oxford, in the Order of their Foundation.

Names.	Date of Foundation.	Founders.	Visitors.	On the Foundation.	Members in 1839.		Patronage. Advowsons.
					Of the Senate.	Total on the Board.	
1. University College.	1253	William of Durham.	The Queen.	Master, 13 fellows, 19 scholars, with some exhibitioners.	117	234	10
2. Balliol College.	between 1263 and 1268	John Balliol of Bernard Castle, and Dervorguilla his wife.	Archbishop of Canterbury.	Master, 12 fellows, 14 scholars, and a considerable number of exhibitioners; 10 from the university of Glasgow.	136	309	20
3. Merton College.	1264, removed to Oxf. 1274	Walter de Merton, bishop of Rochester.	Archbishop of Canterbury.	Warden, 24 fellows, 14 post-masters, 4 scholars, 2 chaplains, and 2 clerks.	64	133	18
4. Exeter College.	1314	Walter de Stapledon, bishop of Exeter.	Bishop of Exeter.	Rector, 25 fellows, and 19 scholars and exhibitioners.	137	326	12
5. Oriel College.	1326	Adam de Brome.	The Queen.	Provost, 18 fellows, and 17 scholars and exhibitioners.	164	327	13
6. Queen's College.	1340	Robert Egglesfield.	Archbishop of York.	Provost, 24 fellows, 10 masters of arts, 4 scholars, 24 exhibitioners, &c.	181	276	29
7. New College.	1386	William of Wykeham, bishop of Winchester.	Bishop of Winchester.	Warden, 70 fellows and scholars, 10 chaplains, an organist, 3 clerks, and 16 choristers.	71	153	36
8. Lincoln College.	1427	Richard Fleming, bishop of Lincoln.	Bishop of Lincoln.	Rector, 12 fellows, 8 scholars, 12 exhibitioners, and 1 Bible clerk.	70	147	11
9. All Souls College.	1437	Henry Chichele, archbishop of Canterbury.	Archbishop of Canterbury.	Warden, 40 fellows, 2 chaplains, and 2 Bible clerks.	77	105	17
0. Magdalen College.	1456	William of Waynfleet, bishop of Winchester.	Bishop of Winchester.	President, 40 fellows, 30 demies, schoolmaster, usher, 4 chaplains, organist, 8 clerks, and 16 choristers.	130	171	38
1. Brasen-Nose College.	1509	William Smith, bishop of Lincoln, and Sir Richard Sutton, Knt.	Bishop of Lincoln.	Principal, 20 fellows, and a considerable number of scholars and exhibitioners.	218	390	42
2. Corpus Christi College.	1516	Richard Fox, bishop of Winchester.	Bishop of Winchester.	President, 20 fellows, 20 scholars, 2 chaplains, and 4 exhibitioners.	83	120	22
3. Christ Church.	1525	Cardinal Wolsey, suspended by Henry VIII. and re-established in 1532.	The Queen.	Dean, 8 canons, 101 students, 8 chaplains, organist, 8 singing men, and 8 choristers.	486	897	91
4. Trinity College.	1554	Sir Thomas Pope, Knt.	Bishop of Winchester.	President, 12 fellows, 13 scholars, and 3 exhibitioners.	119	289	9
5. St John's College.	1555	Sir Thomas White, Knt.	Bishop of Winchester.	President, 50 fellows and scholars, chaplain, organist, 6 singing men, 6 choristers, and 2 sextons.	124	230	29
6. Jesus College.	1571	Hugh Price, D. C. L. treasurer of St David's.	Earl of Pembroke.	Principal, 19 fellows, 18 scholars, and a number of exhibitioners; all except two fellows must be natives of Wales.	54	135	22
7. Wadham College.	1613	Nicholas Wadham, Esq., and Dorothy his wife.	Bishop of Bath and Wells.	Warden, 15 fellows, 15 scholars, 2 chaplains, 2 clerks, and a number of exhibitioners.	87	245	9
8. Pembroke College.	1624	Thomas Tesdale, Esq. and Richard Wightwick, B. D.	Chancellor of the university.	Master, 14 fellows, and 29 scholars and exhibitioners.	111	187	13
9. Worcester College.	1714	Sir Thomas Cookes, Bart.	Bishops of Oxford and Worcester, and vice-chancellor of university.	Provost, 21 fellows, 16 scholars, and 3 exhibitioners.	107	238	8
0 St Mary Hall.	1333	......	Chancellor of the university.	Principal, vice-principal, and 3 exhibitioners.	20	65	...
1. Magdalen Hall.	1487	......	Ditto.	Principal, vice-principal, and some scholars and exhibitioners.	58	179	1
2. New Inn Hall.	1438	......	...	Principal.	4	52	...
3. St Alban Hall.	About 1550	......	...	Principal and vice-principal.	9	22	...
4. St Edmund Hall.	About 1269	......	...	Ditto. ditto.	57	101	...

[1] M'Culloch's Stat. Acct. ii. 341.

Cambridge.

UNIVERSITY OF CAMBRIDGE.

Origin.

It is probable that Cambridge first became a seat of education in the seventh century, when, according to Bede, Sigebert, king of the East Angles, with the assistance of Bishop Felix, instituted in his kingdom a school for learning, in imitation of those which he had seen during his exile in France.[1] This school is supposed to have been fixed at Cambridge, which then bore the name of Cairgrant, and was one of the most celebrated towns in Britain, though the fact is not asserted by Bede. How long the school thus founded continued to flourish, we are not informed; but the complaint of Alfred that, in his youth, when he had leisure to be instructed, he could not find teachers, would lead to the inference that in his time no public seminaries existed. The merit of restoring, or probably of founding, the school which formed the nucleus of the future university, is ascribed to Edward the Elder, son of Alfred; who appears, from the chronicle of Hyde Abbey, to have erected, "at his own expense, halls for the students, and chairs and seats for the doctors;" at the same time appointing teachers, and adopting other necessary measures, which seemed to secure the stability of the institution.[2] The importance of the town, however, rendered it liable to numerous vicissitudes, and exposed it to the ravages of the Danes and Saxons. In the year 1010 it was burnt and plundered by the Danes; and towards the end of the eleventh century, William the Conqueror destroyed a part of it, to make room for the fortress which he found it necessary to erect for the purpose of overawing the refractory monks of Ely. In all these reverses of fortune the scholastic establishments had their full share.

History.

The reign of the succeeding monarch was not more favourable to the tranquillity of the town, and the schools were therefore for some time abandoned. Henry I., who is said to have been educated at Cambridge, conferred on the town some valuable privileges, and induced the wandering students to return to their former dwellings. In his reign (1109) Joffrid, abbot of Croyland, "sent to his manor of Cottenham, near Cambridge, Gislebert, his fellow-monk, and professor of divinity, with three other monks who had followed him into England. These being well versed in philosophy and other sciences, went daily to Cambridge, and having hired a public barn, made open profession of their sciences, and in a little time collected a great concourse of scholars. In the second year after their arrival, the number of their scholars from the town and country increased so much, that there was no house, barn, or church capable of containing them. For this reason they separated into different parts of the town, imitating the plan of the university of Orleans."[3] An old building is still pointed out as the representative of the barn in which these missionaries taught. The number of students continued to increase, and the school gradually acquired celebrity, till 1174, when nearly the whole town was consumed by a fire "so merciless," says Fuller, "that it only stopped for want of fuel to feed its fury." From this disaster the seminary appears to have speedily revived; and, in 1209, it received an accession of numbers from Oxford, in consequence of an act of severity on the part of King John, which has been already alluded to. This, according to Mr Hallam,[4] is the earliest authentic mention of Cambridge as a place of learning; though he admits the reasonableness of the conjecture, that the Oxford scholars would not have removed to a town so distant, if it had not already been the seat of academical instruction. Cambridge was not yet permitted to enjoy the tranquillity which is indispensable for the successful prosecution of study. In the year 1215, during the contentions between King John and his barons, the town was laid waste; and it shared the same fate afterwards in the civil war under Henry III. Previously to this last disaster, the king had extended his patronage to the rising seminary, in consequence of some of the Parisian scholars who had accepted his invitation having settled there, and had by public letters confirmed the authority of the academical officers, and checked the disorders which from time to time manifested themselves. In these remote times the students lodged in the houses of the citizens, or in halls or inns hired of them, under the superintendence of principals, who were responsible to the chancellor for the conduct of their pupils.[5] The extravagant demands for rent gave rise to numerous disputes between the scholars and townsmen, and drew from the king in 1231 a public letter ordaining that lodgings or hostels (*hospitia*) "should be taxed according to the custom of the university, namely, by two masters, and two respectable and lawful men of the town, and let to the scholars according to their valuation." This order was repeated in letters patent of the same king, with the addition that the valuation should be renewed every five years.[6] A similar regulation prevailed at Oxford.

The most important of the public instruments of Henry III. relative to the university, besides those already mentioned, are, his letter addressed to the sheriff of the county (*vicecomes*), calling upon him "to repress the insubordination of the clerks and scholars, and to enforce obedience to the injunctions of the bishop of Ely, either by imprisonment or banishment from the university, according to the discretion of the chancellor and masters;" his letter to the bishop of Ely, ordering that "clerks who were contumacious and rebellious against the chancellor should be imprisoned or banished from the town;" and his letter addressed to the sheriff, in the 26th year of his reign, in which it is ordered that "when any clerk of the university of scholars studying at Cambridge, has been guilty of any misdemeanour, and has been convicted by the university, and sentenced to imprisonment, if the burgesses of the town are negligent in carrying the sentence into effect, or are unable to do so, the sheriff, on the warrant of the chancellor, is to cause such malefactor to be committed to prison, and kept in safe custody, until the chancellor demand his liberation."[7] The mixture of jurisdictions implied in these documents is singular; the authority of the bishop of Ely, as diocesan, is distinctly recognised; but delinquents are to be tried by the chancellor and masters, and the civil power of the sheriff is necessary to carry their sentence into execution. It likewise appears from what has already been stated, that Cambridge, though not yet incorporated, was recognised as a university,[8] and received a support from the civil power which was not given to the continental universities. A nore explicit recognition of the privileges of the university ; found in a royal enactment of the forty-fifth of Henry II. (1260), prohibiting "the king's justices from interfer- ng in hearing and determining offences between scholars nd laymen;" meaning by the latter term those who were ot scholars.[1]

[5] The highest officer of the university was originally called Rector. Mr Dyer says the name Chancellor occurs in 15th Henry III., and supposes it was applied to him about the beginning of this reign. History, i. 60, note. Privileges, i. 404, 485.

[6] Dyer's Privileges, i. 5 and 7.

[7] Dyer's Privileges, i. pp. 5, 6, 62.

[8] Mr Dyer states (Privileges, i. 412, note) that he finds the term *University* applied to Cambridge in a public instrument of 1223. Mr Hallam (Mid. Ages, iii. 527, note) assigns the date of its first incorporation to the 15th of Henry III., or 1231; but in Hare's Register of the Charters, and other monuments of the liberties and privileges of the university, which is the authority on which the university relies, there is no charter of incorporation of this year, or indeed any of this monarch. It is probable, therefore, that Mr Hallam has mistaken

The royal support thus given to the university was not ıffieient to check the spirit of insubordination among the cholars, or to prevent them from engaging in frequent con- icts with the townsmen. On one occasion the students om the north and south, arranged in opposite sides, es- oused the cause of two of their countrymen who had quar- elled, and proceeding from words to blows, threw the uni- ersity and town into the utmost disorder. The chancel- r interfered, but academical authority was too weak; and ıe townsmen who were called to his aid, mixing in the ay, contributed only to increase the confusion. Public under, burning of records, and every species of horror en- ıed. The king sent a delegate to inquire into the dis- ıtes, and to cause summary justice to be executed on some the delinquents. Sixteen of the townsmen were hanged, ıd others belonging both to the university and town took fuge in the religious houses, or were committed to the mmon gaol. By this means peace was restored; but any of the scholars retired to Northampton, where they ere allowed by the king to form themselves into a literary eiety.[2] These tumults were likewise increased by the urnaments which were held at Cambridge during the irteenth century, and which not only interrupted the ıdies of the university during their continuance, but gave e to animosities which did not easily subside. To re- ove this impediment to learning, Henry III. issued letters tent, which were confirmed by Edward II., forbidding any urnament from being held within five miles of the town.[3]

The most important document of Henry III. is the famous mposition (1270) between the scholars and burgesses, nfirmed hy royal authority, which ordained that "a certain ımber of the scholars and the townsmen should be bound oath to take the names of all the principal houses in the wn, and of those who dwelt in them, so that no person ould be lodged therein who could disturb the public peace." fenders who could not be expelled by the authorities of e university and town, were to be denounced before the ng and his council.[4] The effects of this arrangement were neficially felt by the university; and accordingly the rrent of its history was not disturbed by any violent agi- ions during the next century. In the year 1381, the hos- ty of the townsmen to the students displayed itself with eat violence, which led to the destruction of the charters the university, and those of Bennet College. After nume- ıs other acts of violence, the tumult was suppressed by the hop of Norwich, and the principal leaders were punished. e mayor was deprived of his office, and the liberties of town were declared forfeited, and bestowed on the vice- ıncellor, in whom they were vested till the reign of Henry II. when the corporation was restored, though several of former privileges were retained by the university.

Cambridge.
Charters.

The university obtained its first formal charter of privileges from Edward I. in the twentieth year of his reign (1291). This charter, besides confirming the letters of Henry III. and the Composition, conferred upon the university some new privileges, among which was one, that no one imprisoned by order of the chancellor should be liberated by the mayor and bailiffs under pretext of a king's brief formerly issued.[5] Charters more and more ample were granted by Edward II. Edward III. Richard II. and Henry IV. in the beginning of their reigns, as we have already found to be the case with the university of Oxford. By these charters the university obtained the control over victuallers of all sorts, with power to punish *regraters* and *forestallers*, and to deliver scholastics and clerks from prison; and all causes in which they were concerned, relating to laws, letting of houses, &c., were made cognisable before the vice-chancellor or his commissary. The jurisdiction of this officer was extended to all cases, whether civil or criminal, except those of mayhem and felony, in which one of the parties was a master or scholar. The assize of bread, wine, and beer, with the supervision of weights and measures, which had formerly belonged to the magistrates of the town, were exclusively lodged in the university; and for these privileges the university was to pay into the exchequer a yearly tribute of ten pounds. The mayor and bailiffs of the town were sworn every year, before the vice-chancellor, to keep the peace of the university.

Confirmation.

So far as the extant documents enable us to judge, Cambridge was not much troubled by papal bulls and rescripts;[6] and was less exposed than the sister university to ecclesiastical interference at home. When Edward II., in the tenth year of his reign (1316), granted to the university a charter containing some additional privileges, he solicited a confirmation of them from the papal see. A bull was accordingly issued at Avignon, by John XXII., in the second year of his pontificate (1318), which, after confirming the privileges conferred by former popes and former kings of England, ordains "that there shall be thenceforth at Cambridge a *studium generale*, and that every faculty shall be maintained there; and that the college and masters of the said *studium* shall be accounted a university, and enjoy all the rights which any university whatsoever, lawfully established, can and ought to enjoy."[7] From the date of this bull, Cambridge was recognised among the universities of Christendom.

We have already seen that the jurisdiction of the bishop of Ely, as bishop of the diocese, was in ancient times distinctly acknowledged; but it was soon limited, partly by the concessions of the bishops themselves, and partly by papal authority. Hugh Balsham, the founder of St Peter's College, disclaimed (1275), by a public letter, any intention of derogating from the privileges of the university, or disturbing the jurisdiction of the chancellor, but required all suits to be brought before the chancellor in the first instance, restricting himself to receiving appeals. In the following year the same bishop limited the jurisdiction of his archdeacon.[8] Farther limitations in the power of the

---

of the public letters for a charter of incorporation. (Malden, pp. 93, 94). "Wherever," says Mr Dyer, "we choose to make our stand, ether at the diploma of Henry III. which is undoubtedly authentic, or any which preceded him, that are of doubtful authority, they all pose the existence of a university, but say nothing of its creation: nor, indeed, from the meaning of the word, does it seem to have been essary; the word was previously in use, and suited to a literary as well as any other body: so it was insensibly adopted, without annex- to the term any of that charm attached to it in later years." Privileges, i. 385.

Dyer's Privileges, i. 6.

Dyer's History, i. 62. This *university* lasted only four years. The students were ordered by the king to return to Cambridge in 1264

In the year 1701, when the celebrated Dr Bentley was vice-chancellor, the mayor and corporation of Cambridge gave permission to ers to perform at Sturbridge Fair, which called into exercise the power of the university, and has since prevented a repetition of the offence. ık's Life of Bentley, i. 152.

Dyer's History, i. 67. Privileges, i. 66.

[5] Dyer's Hist. i. 67. Priv. i. 73.

In the reign of Henry VIII. the university and colleges were ordered to send in all their grants, charters, statutes, and bulls; and though charters, &c. were restored, it does not appear that the bulls were returned. It is doubtful, therefore, if we possess the most ancient do- ents of this kind. See Dyer's Priv. i. 394.

This bull is given at full length by Dyer (Priv. i. 60 and 61), who successfully proves (p. 410) that it was issued by John XXII., and as Mr Parker supposes, by John X., whose pontificate extended from 914 to 928.

[8] Dyer's Privileges, i. 8. Malden, p. 102.

Cambridge. bishop were made in the early part of the reign of Edward III.; and in the thirty-sixth year of the same reign, letters patent were granted, by which the scholars were protected from being summoned out of the university into any ecclesiastical court; and appeals to any ecclesiastical court whatever were prohibited in cases cognisable by the chancellor. These immunities were confirmed by royal letters to the bishop of Ely in the 15th of Richard II.[1] The university elected its chancellor and other principal officers, but the confirmation of the bishop of Ely was anciently required.[2] This confirmation was however dispensed with by a bull of Boniface IX. in 1401; and in 1430, Pope Martin V. appointed a commission to inquire whether the university by grant or custom was subject to the ecclesiastical jurisdiction of the chancellor, and exempted from that of *all others;* empowering his delegates, if they should find it so, to confirm by his authority that jurisdiction and exemption, which was accordingly done. The sentence of the delegates was ratified by a bull of Eugenius IV. in 1433. The university was thus relieved from the jurisdiction of the bishop of the diocese, but not from that of the archbishop of the province. Two examples of metropolitan visitation are recorded, the one in 1309, and the other in 1401; but in neither case does the archbishop appear to have acted on his own authority. Mr Dyer[3] shows that the former visitation was undertaken by the authority of letters patent from the king. The proceedings of the latter, which had special reference to the heresy of Wycliffe, were confirmed by act of parliament. The right of visitation and inspection is vested in the sovereign.

In the reign of Henry V. the university obtained two remarkable privileges. The one was a public statute, ordaining that none should practise the art of medicine except those admitted in the universities, and approved by them; offenders were to be punished at the discretion of the privy council. The other was a mandate from the archbishop, granted with the consent of the prelates of his province, that patrons should bestow ecclesiastical benefices only on graduates and students of the university. Some additional privileges were conferred by Edward IV. and Henry VII. The changes which took place in the religion of the state during the four succeeding reigns affected considerably the internal arrangements and prosperity of the university. Queen Elizabeth, in the third year of her reign, granted to it an extensive charter; and by the act of parliament 13 Eliz. c. 29, for the incorporation of the two English universities, this and all preceding grants from Henry III. downwards were confirmed, and the university was declared to be incorporated by the name of the "Chancellor, Masters, and Scholars."

Colleges. Our materials do not enable us to give so minute an account of the collegiate foundations of Cambridge, and of other religious houses for the residence of students, as we have already given respecting those of Oxford. In the early part of the thirteenth century, the halls or hostels are said to have been very numerous, and to have been crowded with students. This is indeed implied in the public letters of Henry III.; and it would appear from the terms of the Composition, that the *hospitia*, to which it referred, were liable to fluctuation and change. The principal houses were those of St Mary, St Bernard, St Thomas, and St Augustin, assigned to artists; and St Paulinus, St Nicholas, St Clement, and Hovens, to students of the civil and canon law. Several of these houses were at length deserted, and sunk into decay; others, being purchased by patrons of literature, and obtaining charters of incorporation, are represented by the present colleges. Caius says there had been twenty hostels, of which seventeen remained in his time.[4] Of the existing colleges, Peter-house, or St Peter's College, was founded so early as 1257; five were incorporated during the succeeding century, four in the fifteenth, six in the sixteenth, and one, Downing College, so late as 1800. The term *hall* is not applied, as at Oxford, to houses without endowment, but is used indiscriminately with *college.*

The university of Cambridge is incorporated (13 Eliz. c. 29) by the name of the "Chancellor, Masters, and Scholars of the University of Cambridge," and consists of seventeen colleges, or societies, devoted to the study of learning and science. Each college is a body corporate, bound by its own statutes, but is likewise controlled by the paramount laws of the university, each furnishing members both for the legislative and executive government of the whole. The statutes of Elizabeth are the foundation of the existing government, and form the basis of all the subsequent legislation; indeed no grace of the senate is considered valid which is inconsistent with these statutes, and certain nearly contemporary interpretations of them, or with king's letters, which have been accepted and acted on by the university. The principal officers of the university have nearly the same offices and titles as at Oxford; namely, the chancellor, high steward, vice-chancellor, public orator, two proctors, a librarian, two taxers (who regulate the markets, assize of bread, &c.), professors and public lecturers, two scrutators, &c. There are also two officers peculiar to Cambridge, styled moderators,[5] who are deputies of the proctors, and whose office it is to superintend the exercises and disputations in philosophy, and the examinations previous to the degree of bachelor of arts. There are, besides, a commissary, who is an officer under the chancellor, and an assessor, whose duty it is to assist the vice-chancellor in his court. The chancellor is always a nobleman, and is elected by the senate. His office is biennial, or tenable for a longer period by the consent of the university. The other officers are elected nearly in the same manner as at Oxford.

The business of the university is conducted by the Senate, which consists of two Houses, denominated the Upper or Regent House, and the Lower or Non-Regent House. All masters of arts, or doctors in one or other of the faculties of divinity, civil law, or physic, having their names upon the college-boards, holding any university office, or being resident in the town of Cambridge, are members of the senate. Masters of arts of less than five years' standing, and doctors of less than two, compose the regent or upper house, or, as it is otherwise called, the *white-hood* house, from the members wearing their hoods lined with white silk. Masters of arts of more than five years' standing, but who have not advanced to the degree of doctor, constitute the non-regent or lower house, otherwise called the *black-hood* house, its members wearing black silk hoods. But doctors of more than two years' standing, with the public orator, may vote in either house, according to their pleasure.

Besides the two houses, there is a council called the Caput, chosen annually on the 12th of October, by which every university grace must be approved before it can be introduced in the senate. The caput consists of the vice-chancellor, a doctor in each of the faculties of divinity, civil law, and physic, and two masters of arts, who represent the regent and non-regent houses. The vice-chancellor is a member of the caput by virtue of his office; the other members are chosen in the following manner: the vice-chancellor and the two proctors severally nominate five persons properly qualified for the trust, and out of the fifteen the heads of colleges, doctors, and scrutators, choose five. The vice-chancellor's list is, in general, honoured with the appointment. A few days before the beginning of each term, the vice-chancellor publishes a list of the days on which a Congregation or assembly of the senate will be held for transacting university business; but in case of emergency, the vice-chancellor summons a congregation for the despatch of extraordinary affairs. Any number of members of the senate, not less than twenty-five, and including the proper officers who are obliged to be present, constitutes a conegation, and may proceed to business. There are also statut- ɔle congregations, or days of assembling enjoined by the statutes, r the ordinary routine of university affairs, such as conferring grees, electing officers, &c. Every member has a right to pre- nt any proposition, or grace, to the consideration of the senate; it previously to its being voted upon by the two houses, it must approved by the caput, each member of which has a *negative* ice. After a grace has passed the caput, it is read in the non- gent house by the senior scrutator, and also in the regent-house the senior proctor, and the congregation is prorogued by the ce-chancellor. It is read in like manner at the second congre- tion; and if a *non-placet* is put in by a member of the non-regent use, it is there voted; and if the number of *non-placets* is equal or exceeds that of the *placets*. the grace is thrown out, and can oceed no farther. But if the *placets* exceed the *non-placets*, it is rried up to the regent-house, where it undergoes the same pro- ss; and if it passes through both houses, it is considered a regular of the senate. No degree is ever conferred without a grace that purpose; those for bachelors of arts, honorary degrees, d masters of arts of King's College excepted, which require to read at one congregation only. A grace in this instance is med a Supplicat, and is signed by the prælector of the college which the candidate belongs, the subscriber being made respon- le for the assertion which it contains. An assembly of the ate held out of term-time is called a *Convocation;* in which case race is immediately passed to convert the convocation into a gregation, when the business proceeds in the ordinary manner.

Cambridge.
Professors.

The Professors, as at Oxford, are not directly concerned in the public education of the university. Many of them deliver courses of lectures, which are in general better attended and more celebrated than those in the sister university; but these are on branches of learning or science of recent growth, and not on subjects included in the ancient and regular studies of the place. Attendance on their lectures is in no way required, nor does the university take cognisance of it. This rule is subject to two exceptions; students proceeding to the lower degrees in the civil law and medicine, are required to present testimonials of attendance on the lectures of particular professors. The professors are paid from various sources, some from the university-chest, others by the government, or from estates left for that purpose. Education is conducted entirely by the tutors of the various colleges, assisted, as at Oxford, by private tutors.

Income.

The annual income of the university arises from various sources. The rectory of Burwell, and a farm at Barton, produce about L.1000 per annum; the produce of fees at matriculations, for degrees, &c. averages about L.2000; and the trading profits of the university press, arising chiefly from its share in the monopoly of printing Bibles, is supposed to be about L.2000. The whole income from every source is believed scarcely to exceed L.5500 per annum. The funds are managed by the vice-chancellor, or by specific trustees, and the accounts are examined annually by three auditors appointed by the senate.

The following table contains a list of the professorships, with the date of their establishment, the salaries, and patronage.

Lady Margaret's professorship of divinity.	1502	20 marks.[1]	Chancellor, doctors, inceptors, and bachelors in divinity.
Regius professorship of divinity.	1540	L.40	Vice-chancellor, master, and two senior fellows of Trinity, &c.
— — — civil law.	1540	40	Crown.
— — — physic.	1540	40	Crown.
— — — Hebrew.	1540	40	Vice-chancellor, master, and two senior fellows of Trinity, &c.
— — — Greek.	1540	40	Ditto ditto.
Professorship of Arabic.	1632	40	Vice-chancellor and heads.
Lord Almoner's professorship of Arabic.	...	50	Lord Almoner.
Lucasian professorship of mathematics.	1663	100	Vice-chancellor and masters of colleges.
Professorship of casuistry.	1683	70	Vice-chancellor, professors of divinity, and master of St Peter's.
— — chemistry.	1702	100	Members of senate.
Astronomy and experimental philosophy.	1704	500	Vice-chancellor, masters of Trinity, Christ's, Caius, &c.
Professorship of anatomy.	1707	100	Vice-chancellor, proctors, and junior doctors.
Regius professorship of modern history.	1724	400	Crown.
Professorship of botany.	1724	200	Crown.
— — geology.	1731	...	Members of senate, chancellor, archbishop of Canterbury, &c.
— — astronomy and geometry.	1749	300	Lord high chancellor, president of the Privy Council, &c.
Norrisian professorship of divinity.	1760	105	Heads of houses.
Natural and experimental philosophy.	1783	160	Regent masters of arts.
Downing prof. of the laws of England.	1800	200	Archbishops of Canterbury and York, master of St John's, &c.
— — medicine.	1800	200	Ditto ditto.
Professorship of mineralogy.	1808	100	
— — political economy.	1828	...	
— — music.	1684	No salary.	Senate.
Barnaby lecturer.	1524	...	
Lady Margaret's preacher.	1503	10	Vice-chancellor and heads of houses.
Sadlerian lecturer.	1710	40	
Christian advocate.	1789	...	
Hulsean lecturer.	1789	300	Vice-chancellor, master of Trinity, &c.

The organization of the collegiate bodies, and their rules of ernment, at Cambridge, vary from those of Oxford only in a unessential particulars. The three ranks of independent ler-graduates in the former university are noblemen, fellow- nmoners (so called originally from having their commons, or ege dinner, at the same table with the fellows), and pensioners. th respect to the discipline and government of those in *statu illari*, it is to be observed, that students at Cambridge do not scribe to the thirty-nine articles either at matriculation or af- wards; although, on taking their degree of B. A., they are ged to sign a declaration of adherence to the Church of Eng- l. Lodging in college is not enforced on under-graduates if re be not room within the walls of the building to accommodate m. It is chiefly to this circumstance that the great increase of lents at Cambridge of late years is to be attributed, the mem- s of the other university being necessarily limited by the ount of room for lodging them. With regard to members on foundation, the scholars of most colleges at Cambridge, being erally elected by free competition from among the under- duate members, form rather a distinguished class among the lents, than a body distinct from the independent members, and sen without free competition, as is generally the case at Ox- l. A distinction exists between two different classes of fellowships in most houses at Cambridge, which is only partially known at Oxford; viz. between the foundation-fellowships, and what are termed the bye-fellowships and appropriated fellowships; the former being part of the original endowments, and generally open to all the world; the latter, founded by subsequent donations, and frequently limited by local and other restrictions. In most colleges, the governing body is composed of the foundation-fellows only; and they alone are eligible to college office. It has been already stated, that the general usage, at Cambridge, is for each college to elect its fellows from among its own members, whether scholars or independent: the chief exceptions to this rule occur in the small colleges, when they are in want of some individual to fill the office of tutor, and no satisfactory candidate presents himself in their own number.

"In general, it may be said that the Cambridge system is less strict in point of external discipline, and the under-graduates under rather less close control, than at the sister university; on the other hand, that emulation and close attention to study are more favoured and encouraged. All the regulations, both of the colleges and university, tend in this direction. Open competition, and rank according to merit, form the cardinal principles of the academical constitution, as far as it relates to students."[2]

Terms.

The academical year consists of three terms, viz. Michaelmas,

---

[1] The salary was augmented by James I. with the rectorial tithes of Ferrington, Norfolk.

[2] M'Culloch's Stat. Acct. ii. 350, 351.

Cambridge.

Admission.

Lent, and Easter, and includes nearly seven months. The mode of admission on the boards of a college is either by a personal examination before the tutors and officers, or through a recommendatory certificate, specifying the age, qualifications, &c. of the candidate, signed by a master of arts of the university, and accompanied by a deposit called caution-money.[1] This is generally done before the end of Easter term; and if the certificate be deemed satisfactory, the name is at once entered on the boards of the college, and the student usually comes into residence about the 20th of October following, when the academical year begins. The following are the principal regulations necessary for proceeding to degrees.

Degrees. The distinguishing characteristic of this university has, for nearly two centuries, been the pursuit of mathematical studies, and of those branches of natural philosophy which depend on them. To these the lectures, both public and private, are chiefly devoted, and thus present to the student the only means by which he can attain the honours and emoluments either of the university or of his college. The study of classical literature, which is now prosecuted to an extent not inferior to that in the sister university, is of comparatively recent introduction. Original composition forms no part of the examination for honours, but it is made a leading feature in the competition for scholarships and other prizes.

Bachelor of Arts (B. A.), twelve terms, of which ten must be in residence. Privy councillors, bishops, noblemen, sons of noblemen, the relations of the king, with their eldest sons, baronets and knights, are admissible after having kept seven terms.

Master of Arts (M. A.), three years after taking a bachelor's degree.

Bachelor in Divinity (B. D.), must be M. A. of seven years' standing. By the 9th statute of Queen Elizabeth, persons admitted of any college, when upwards of twenty-four years old, are permitted to take the degree of B. D. after ten years, without having previously taken any other, and are styled *Ten-year-men.* The last two years must be in residence.

Doctor in Divinity (D. D.), must be B. D. of five, or M. A. of twelve years' standing.

Bachelor in the Civil Law (B.C.L.), must be of six years' standing complete, and must reside the greater part of nine several terms. The candidate is required to pass the "previous examination," to attend the lectures of the professor of the civil law for one year, and to be examined by the professor. A B. A. of four years' standing is also admissible to this degree.

Doctor in the Civil Law (D. C. L.), must be B. C. L. of five or M. A. of seven years' standing.

Bachelor in Physic (M. B.), must be of five years' standing, and must reside nine terms. The candidate is required to attend a complete course of lectures on the principles of pathology and practice of physic by the regius professor of physic, a course of lectures by the professors of anatomy, chemistry, and botany; to undergo an examination by each of these four professors, and to produce a certificate of having acquitted himself satisfactorily.

Doctor in Physic (M. D.), subject to the same regulations as a D. C. L.

Licentiate in Physic is required to be M. A. or M. B. of one term's standing after he has been admitted M. B.

Bachelor in Music (Mus. B.), must enter his name in some college, and compose and perform an exercise in his art.

Doctor in Music (Mus. D.), generally a Mus. B., and his exercise is the same.

Examinations. The system of public examinations which is pursued at Cambridge differs in many respects from that which prevails at Oxford; and as these examinations are intended to exhibit the result of the academical instruction, a short account of them will convey to the reader a pretty correct notion of its merits. The examinations take place in the Lent term of each year, and are conducted by the moderators, and by examiners appointed by the senate. It may be premised, that the course of study preparatory to the degree of B. A. is comprehended under the three heads of Natural Philosophy, Theology and Moral Philosophy, and the Belles Lettres. The first comprises Euclid's Elements, the principles of algebra, plane and spherical trigonometry, conic sections, mechanics, hydrostatics, optics, astronomy, fluxions, Newton's Principia, Increments, &c.; the second, Beausobre's Introduction, Doddridge's and Paley's Evidences, the Greek Testament, Butler's Analogy, Paley's Moral Philosophy, Locke's Essay, and Duncan's Logic; and the third comprehends the most celebrated Greek and Latin classics. The under-graduates are examined in their respective colleges yearly or half-yearly, on the subjects of their studies; and, according to the manner in which they acquit themselves in these examinations, their names are arranged in classes, and those who obtain the honour of a place in the first class receive prizes according to merit.

The first university or "previous" examination (technically called the "little go)" takes place in the Lent term of the second year from that in which the student commences his academical residence, and is conducted by four examiners appointed by the senate. The subjects of examination are one of the four Gospels, or the Acts of the Apostles, in the original Greek, Paley's Evidences of Christianity, and one of the Greek and one of the Latin classics. Every student is required to translate some portion of each of the subjects appointed, to construe and explain passages of the same, and to answer printed questions relating to the evidences of Christianity. After the examination, the students are arranged in two classes; those who have passed with credit, and those to whom the examiners have only not refused their certificate of approval. Rejected candidates are required to attend the examination of the following year. A certificate of having passed this examination is indispensable for proceeding to the degrees of B. A., M. B., and B. C. L.

The student has next to perform the usual exercises required by the statutes for his degree; or, in academical language, to keep an Act under a moderator. This exercise, which at Oxford has almost fallen into disuse, is performed at Cambridge only by those who aspire to university honours.[2] In the Lent term of his third year, the moderator or examiner gives notice to a student that he is to keep an act, who thereupon writes three questions, which he proposes to maintain and defend. The first question is always from Newton's Principia, the second from some other mathematical work, and the third from some moral or metaphysical writer. The moderator, on receiving these, nominates three students, whose attainments, he thinks, will enable them to prepare arguments on the other side. On the day appointed, the moderator having taken his chair, the candidate for the degree, who is termed the *respondent*, reads a Latin thesis, usually on the third subject; after which the others, styled *opponents*, propose their arguments, in syllogistic form, against the several positions, the discussion being conducted in Latin. If the respondent can answer them, he does so; if not, the moderator endeavours, by questioning him, to ascertain from what defect in his knowledge this arises. Each opponent, as he is dismissed, is also questioned by the moderator.

To check the practice of "degrading," or postponing for a year, the degree of B. A., which had become common among the students, a statute was enacted in 1829, by which degraders are not allowed to present themselves for university scholarships, or any other academical honours, without special permission.

The *Senate-House Examination* also takes place in the Lent term, when all the men of the same year, except those who have degraded, are brought into competition at the same time. The questionists,[3] or candidates for the degree of B. A., are divided into six classes, determined by the "exercises" in the schools of the preceding year, and sometimes by the report of their college tutors. The first four classes include those who are candidates for honours; those of the two remaining classes are applicants merely for the degree.

The examination of candidates for mathematical honours, technically called the *Mathematical Tripos*, is confined to mathematics and the cognate sciences, with subsidiary questions in divinity, logic, and moral philosophy. It lasts eight days, the first five of which are devoted entirely to mathematics, the time of examination for each day being five hours and a half. During the first four days the same questions are proposed to all the classes; on the fifth a distinction is made in this respect between the first and last two. The examination on the first day extends only to such parts of pure mathematics and natural philosophy as do not require the method of the differential calculus. On the second and third days, the questions from books include, in addition to the above subjects, the parts of natural philosophy somewhat more advanced, and the simpler application of the calculus. The fourth day's examination extends to subjects of greater difficulty, care however being taken that there be some questions suitable for the lower classes. On the fifth day the classes are arranged according to a settled plan, when the questions proposed to all the classes are xed upon by the moderators and examiners in common; but the ıty of examining the answers to the questions is apportioned nong the moderators and examiners, as the plan directs. On e sixth day the four classes are examined in logic, moral philosophy, and divinity. The mathematical examination is resumed the seventh day; and on the following morning are published e classifications or *brackets*, arranged according to the order of erit, and each containing, alphabetically, those who have shown emselves nearly equal. Those between whom the examiners cant assign a difference of merit are *bracketed* as equals. At the close the examinations, a select number, thirty at least, of those who ve most distinguished themselves, are recommended to the ctors for their approbation, and their names are set down acding to merit, and classed in three divisions, viz. wranglers, ior optimes, and junior optimes, which constitute the three ors of honour. The highest of all is the senior wrangler for the r, "the greatest of English academical honours."

---

[1] The caution-money for a nobleman is L.50; for a fellow-commoner, L.25; for a pensioner, L.15; and for a sizar, L.10. This money remains in the hands of the tutor or sponsor, and is not returned till a person takes his name off the boards.

[2] By special composition between the university and King's College, its under-graduates do not keep any public exercises in the schools, nor are they in any way examined for the bachelor of arts degree.

[3] *Questionist* is the name given to a student during the last six weeks of preparation for taking his degree.

he examination of the questionists of the fifth and sixth clas s, who are not candidates for honours, is conducted differently. e subjects and exercises proposed are the same for all, and em ce Euclid's Elements, arithmetic, and algebra, with some of elementary parts of natural philosophy; Homer and Virgil,[1] uding questions in grammar, history, and geography; Paley's idences, and Locke's Essay. Of the six examiners, two con themselves to mathematics, two to classics, and two to moral losophy. The examination lasts six days, and is conducted irely by printed papers. The questions proposed are of an nentary character, and presuppose very moderate attainments he part of the questionists. The examiners are strictly en ed to take care that the number of the questions to be an red, and the length of the passages to be translated, in any one er, do not exceed what a person well prepared may be expected nswer and translate in the time allowed. The names of the lidates comprehended in these two classes are also arranged numerically according to merit, but are not published in the calendar.

Cambridge.

The candidates are then required to take the oaths of allegiance and supremacy, and to observe the statutes of the university; and having also subscribed that they are *bonâ fide* members of the Church of England, are admitted to their degrees by the vice-chancellor.

Classical Tripos.

In addition to the examination thus described, there is also an examination in classical learning, or a *Classical Tripos*, which takes place on the fourth Monday after the general admission to the bachelor's degree, and continues five days. It is a voluntary competition, to which those only who have obtained mathematical honours are admissible. Translations are required of passages selected from the best Greek and Latin authors, with written answers to questions arising immediately out of the passages; but no original composition either in Greek or Latin. The names of those bachelors who pass this examination with credit are arranged in three classes according to their respective merits.

Besides the honour of occupying a high place in the tripos lists, Cambridge holds out to the ambitious student many strong inducements to exertion, in the prizes which are annually submitted for competition. Those to which the greatest degree of importance is attached are *Smith's Prizes* and the *Chancellor's Medals*. The former are assigned to two commencing bachelors of arts, for proficiency in mathematics and natural philosophy; and as the competition takes place soon after the mathematical tripos, the adjudication of them forms a severe test of the accuracy of the previous decision. It sometimes happens that the judgment of the tripos examiners is reversed, and the second wrangler becomes first prizeman. The chancellor's medals are given to two commencing bachelors of arts, who must be senior optimes at least in classical merit. For these there is also a separate competition, but it generally happens that the first medal is gained by the person whose name is at the head of the classical tripos.

The following are the existing Colleges and Halls at Cambridge, in the Order of their Foundation.

Names.	Date of Foundation.	Founders.	Visitors.	On the Foundation.	Members in 1839.		Patronage.	
					Of the Senate.	Total on the Boards.	Advowsons.	Schools.
St Peter's College.	1257	Hugh de Balsham, bishop of Ely.	Bishop of Ely.	Master, 14 foundation and 10 bye-fellows, and 59 scholars.	94	194	11	1
Clare Hall.	1326	Elizabeth de Burgo.	Chancellor and two persons appointed by grace of the senate.	Master, 10 senior, 9 junior, and 3 bye-fellows, 44 scholars, and 4 exhibitioners.	77	164	16	...
Pembroke Hall.	1343	Countess of Pembroke.	Lord high chancellor.	Master, 14 foundation and 2 bye-fellows, 23 scholars, and several bye-scholars and exhibitioners.	46	128	10	...
Gonville and Caius College.	1348	Edmund Gonville, increased by John Caius in 1558.	Master of Corpus Christi, senior doctor in physic, and master of Trinity Hall.	Master, 12 senior and 17 junior fellows, 28 scholars, 8 exhibitioners, 1 scholar in chemistry, and 4 in physic.	129	283	22	1
Trinity Hall.	1350	W. Bateman, bishop of Norwich.	Lord high chancellor.	Master, 12 fellows, and 17 scholars.	47	140	9	...
Corpus Christi College.	1351	The brethren of two Cambridge guilds.	Vice-chancellor and two senior D. D., in extraordinary cases the Queen.	Master, 12 fellows, and 61 scholars and exhibitioners.	90	231	11	...
King's College.	1441	Henry VI.	Bishop of Lincoln.	Provost, 7 fellows, and 70 scholars, the latter supplied by a regular succession from Eton College.	76	107	34	...
Queen's College.	1446 1465	Margaret of Anjou. Eliz. Widville, consort of Edward IV.	The Queen.	President, 19 foundation fellows, 1 bye-fellow, 26 scholars.	128	345	10	...
Catharine Hall.	1475	Robert Woodlark, D.D.	The Queen.	Master, 6 foundation and 8 bye-fellows, and 43 scholars.	80	211	4	...
Jesus College.	1496	John Alcock, bishop of Ely.	Bishop of Ely.	Master, 16 foundation fellows, 46 scholars and exhibitioners.	80	183	16	...
Christ's College.	1456 1505	Henry VI. Countess of Richmond and Derby.	Vice-chancellor, and two senior D.D.	Master, 15 clerical and 2 lay-fellows, and 85 scholars and exhibitioners.	101	217	17	...
St John's College.	1511	Countess of Richmond and Derby.	Bishop of Ely.	Master, 32 foundation fellows, 32 appropriated and 8 bye-fellowships, and 181 scholars and exhibitioners.	575	1125	46	6
Magdalene College.	1519	Baron Audley.	Professor of Audley End.	Master, 4 foundation and 13 bye-fellows, and 43 scholars.	79	189	7	...
Trinity College.	1546	Henry VIII., augmented by Mary.	The Queen.	Master, 60 fellows, 69 scholars, besides exhibitioners and sizars.	907	1754	63	4
Emanuel College.	1584	Sir Walter Mildmay.	In some cases vice-chancellor and two senior D.D.; in others, master of Christ's, and two senior D. D.	Master, 12 foundation and 3 bye-fellows, 4 foundation and 32 other scholars.	112	214	17	3
Sidney-Sussex College.	1598	Countess of Sussex.	Sir J. S. Sidney, Bart.	Master, 9 foundation and 3 other fellows, 20 foundation scholars, and 18 other scholars and exhibitioners. A mathematical lecturer.	47	91	6	...
Downing College.	1800	Sir George Downing, Bart.	Lord high chancellor.	This college will consist of a master, 2 professors, 16 fellows, and 6 scholars.	27	52	2	...

[1] The portions of Homer and Virgil required in this examination are the first six books of the Iliad and Æneid.

Cambridge.

The following statistical information relating to the universities of Oxford, Cambridge, and Dublin, was communicated to the meeting of the British Association for the Advancement of Science, at Newcastle, in August 1838, by the Rev. H. L. Jones.[1] The books used by Mr Jones in compiling his tables were the Oxford, Cambridge, and Dublin University Calendars; besides which, private information was relied on in determining the value of fellowships, the number of students resident, &c., points on which the Calendars are silent. In cases of doubt, care was taken to make the estimate below what was believed to be the real value. We can only give the general abstract of Mr Jones' tables.

Mr Jones estimates the average incomes at Oxford and Cambridge as follows:—Heads, L.764. 6s., and L.774; Fellows, L.211, and L.209. 6s.; University Scholars, L.42. 4s., and L.50; College Scholars, &c. L.15; Professors, L.187. 3s., and L.181. 2s.; Lecturers, L.150, and L.47. 7s. The average expenditure of resident members is estimated at L.300 for Oxford, and L.250 for Cambridge, varying however in the different colleges.

UNIVERSITY OF LONDON.

Foundation.

The university of London was constituted by a royal charter, dated the 28th of November 1836, which confers on it the power of granting degrees in arts, law, and medicine, under regulations to be determined by the university, subject to the approval of the secretary of state. By a second charter, dated 5th December 1837, some of the powers granted in the first were modified, and two new members of senate were named. The objects proposed to be effected by the institution, as stated in the charter, are "the advancement of religion and morality, and the promotion of useful knowledge," by holding forth "to all classes and denominations" of persons, without religious distinction, "encouragement for pursuing a regular and liberal course of education," and "rewarding" with academic honours and distinctions those who, by the pursuit of such course of education as the senate, with the concurrence of the government, shall prescribe, have acquired certain ascertained degrees of "proficiency in literature, science, and art." The university consists of a chancellor, vice-chancellor, and thirty-six fellows, who form the senate, or governing body, and are invested with the sole power of managing and superintending its affairs, and of forming regulations for examinations and the granting of degrees, such regulations to be submitted to one of the secretaries of state, and "approved of and countersigned by him." The chancellor is appointed for life by the crown, under the sign manual; the vice-chancellor, whose office is annual, is elected by the fellows from their own number. The original fellows were appointed by the crown, under the sign manual; and the charter provides that, "if at any time, by death or otherwise, their number shall be reduced below twenty-five, exclusive of the chancellor and vice-chancellor for the time being," the members of the senate "shall elect twelve or more fit and proper persons" to complete the requisite number of thirty-six. The power o visitation is retained by the crown. In contemplating the effects likely to result from an establishment invested with such extensive powers, and directed to such noble ends we cannot but regard the university of London as calculated eventually to attain an important station among similar institutions in the empire, and as destined to give a powerful impulse to the advancement of learning and science.

The university comprehends two colleges, named *University College* and *King's College*, both situate in London University College was established by a company of shareholders, for the purpose of furnishing to the inhabitants o the metropolis, at a moderate price, a general education embracing a wider range of subjects than those in which instruction is given at Oxford and Cambridge. Student are admitted without reference to their religious opinions The classes were opened in October 1828; and a second charter of incorporation was granted in 1836. The constitution of both colleges nearly resembles that of the Scotish and German universities, and retains much of the simplicity by which the ancient academical seminaries were characterized. The students do not reside in the college; and the academical discipline is therefore confined to the class room. The professors are dependent on the fees whic they receive from their pupils, and deliver their instructions by means of public lectures, accompanied by catechetical examinations. There are public examinations a the end of the session, when prizes are awarded to th most distinguished students. The government is veste in a council, consisting of a president, vice-president, an twenty-four other members, which has the power to mak regulations, accept endowments, appoint professors, tutor &c. and to manage generally the affairs of the college. A the members of council are elected by the proprietors. Instruction is provided in the three faculties of arts, law, an medicine. The college contains thirty-two professorships nine in literature, six in mathematical and physical science three in ethical and political sciences, three in law, and eleve in medicine; but some of these are held along with othe professorships.

King's College was incorporated by royal charter i 1829, and is confined principally to the education of members of the church of England. The funds for the erectio nd support of the institution were raised partly by dona- ons, and partly by proprietary shares. The government vested in a council consisting of three classes; the visi- or, who is the archbishop of Canterbury; the perpetual overnors by virtue of their office, as the lord chancellor, rchbishop of York, bishop of London, and other high func- onaries; the governors for life, and those who are simply ouncillors. There are thirty-four professorships, embra- ng the same faculties as in University College, with the ldition of lectures in divinity by the principal. By no- ing, perhaps, is the recent institution of these colleges ore distinctly marked, than by the provision which they ive made for the cultivation of the modern languages and erature. Each of them furnishes instruction in English, rench, Italian, and German; and even Chinese is taught a professor.

---

[1] Journal of the Statistical Society of London, vol. i. pp. 385–397.

Besides the members of these two colleges, the university is npowered by the charter of foundation to grant degrees in arts d law to candidates from such institutions within the United ngdom as are or shall be authorized under the sign manual to ue certificates of proficiency, and also to prescribe the courses study, and the modes of education, necessary to entitle the can- ates to be admitted to examination. The following institutions ve consequently been empowered (1841) to issue certificates to ndidates for degrees in arts and law: St Cuthbert's College, haw; Stonyhurst College; Royal Belfast Academical Institu- n; Bristol College; Manchester New College; St Mary's Col- e, Oscott; Carlow College; St Edmund's College, near Ware; merton College; Highbury College; the Colleges of St Peter St Paul, at Prior Park, near Bath; Spring Hill College, Bir- ngham; and Stepney College. The senate, with the ap- bation of the secretary of state, has also the power of selecting medical institutions and schools, "whether corporate or unin- porated," in the metropolis or in other parts of the United King- n, "from which, either singly, or jointly with other medical itutions and schools in this country or in foreign parts, it may proper to admit candidates for degrees in medicine," and to fer degrees on these candidates on their producing certificates naving completed the course of instruction required by the versity. The list of "recognised medical institutions, schools, teachers," dated 9th April 1840, besides the various hospitals medical schools of the metropolis, comprehends the medical ools which have been established in Birmingham, Bristol, Hull, ds, Liverpool, Manchester, Newcastle-upon-Tyne, Sheffield, York; the extra-academical lecturers, composing Queen's ege, Edinburgh, and various teachers who are members of the al College of Surgeons; two medical schools, besides lecturers lasgow; and medical schools in Dublin, Cork, and Belfast.

he Session of the university commences on the first of Octo- for the medical classes, and on the first of November for the ainder, and ends in May. Students in arts, before being itted, must produce a certificate of having completed their six- th year, and are required to undergo a *bona fide* examination ne elements of mathematics, natural philosophy, natural his- , and some of the simpler doctrines of chemistry. They are examined in classics, in the grammatical structure of the Eng- language, and in the outlines of modern history and geogra- Ancient history and geography are embraced in the classical rs. The candidates who have passed are arranged by the ex- ers in two divisions, each in alphabetical order; and any candi- who has passed may, on producing a certificate that he has not pleted his nineteenth year, be examined for honours in ma- natics and natural philosophy, and also in classics; the range amination being made considerably more extensive than that ntrance. The candidates in each of the two divisions are placed in the order of merit; and to the first of each class an bition of L.30. for two years, is assigned. Students of medi- before admission, are required to undergo a similar examina- on the same subjects, varied however to suit their professional s; and those who are admitted have likewise an opportunity taining honours, and of gaining exhibitions of equal amount those in the faculty of arts. The examinations are conduct- means of printed papers; the power being left to the ex- ers of putting *viva voce* questions on the written answers when appear to require explanation.

ne examinations for degrees take place once a year. The ex- ations in arts are in May, and those in law and medicine ovember. The course prescribed in each faculty is exten- and the plan of examination is comprehensive and judicious; our limited space prevents us from giving even an abstract of . The examinations are all conducted by means of printed papers, and are placed under the superintendence of twenty-two examiners, appointed by the senate, and paid by the government. Of these, fourteen are assigned to the faculty of arts, one to the faculty of law, and thirteen to the faculty of medicine. Some of them examine on more than one subject. The professors take no part in the examinations. In each of the faculties there are also examinations for honours, and exhibitions are granted to the successful competitors. The exhibitioners take the designation of University Scholars. The course for the degree of B. A. is two years, and for M. A. four years; for LL. B. one year after taking the degree of B. A.; for LL. D. two years after becoming LL. B.; for M. B. four years; for M. D. a certain prescribed course after taking the degree of M. B. The following are the fees for graduation: B. A. L.10, M. A. L.10, LL. B. L.10, LL. D. L.25, M. B. L.10, M. D. L.10. The estimated public expense of the university, exclusive of the revenue derived from fees, for the year from 1st April 1840 to 31st March 1841, was L.5318. 10s. This money it appropriated to the payment of examiners, registrar, &c.

London.

UNIVERSITY OF DURHAM.

Foundation.

The university of Durham was incorporated by a royal charter, dated the 1st of June 1837, under the name of "The Warden, Masters, and Scholars of the University of Durham," which authorizes the body corporate to have perpetual succession, and a common seal, and to enjoy all the rights and privileges which "are incident to a university established by royal charter." It consequently possesses and exercises the right of granting degrees in all the faculties.

History.

The great and increasing population of the north of England, and its remoteness from the universities of Oxford and Cambridge, had long pointed out the expediency of establishing in this part of the kingdom an institution which should secure to its inhabitants the advantages of a sound yet not expensive education. Accordingly the late bishop of Durham, with the dean and chapter, believing that the means of supplying the deficiency might be provided from the resources of that body, without contravening the principles on which it was incorporated, agreed, by an act of chapter in 1831, to appropriate property producing L.3000 per annum to the support of an academical institution in connection with the cathedral church. The bishop, at the same time, promised to provide eventually for the warden, the professor of divinity, and the professor of Greek, by attaching prebendal stalls to the several offices. In pursuance of this arrangement, an act of parliament was obtained in 1832, authorizing the bishop, and the dean and chapter, to carry their munificent resolution into effect, by empowering them to establish a university for the advancement of learning in connection with their cathedral church. The university was opened in October 1833, and a regular system of instruction commenced. After the course of study had been finally fixed, and the arrangements for conducting the business matured, a statute was passed by the dean and chapter, in July 1835, and approved by the bishop, intrusting the ordinary management of the university, under the bishop as visitor, and the dean and chapter as governors, to the warden, a senate, and a convocation. A body of regulations for conducting the studies and the general business of the university was soon after prepared, and was approved by convocation on the 4th of March 1836. The various acts of the dean and chapter were ratified by the charter of foundation in the following year.

Constitution.

The university consists of a warden or principal, a professor of divinity and ecclesiastical history, a professor of Greek and classical literature, a professor of mathematics, two proctors, and readers in law, medicine, Hebrew, history, and polite literature, natural philosophy, chemistry, and modern languages; with graduates and scholars. The warden and the professors of divinity and Greek are appointed by the bishop of Durham; the professor of mathematics and the other officers are nominated by the dean and chapter. The business of the university is conducted by the warden and a senate and convocation. The senate, which consists of the chief officers of the university, transacts the ordinary business, Durham.

and is competent to originate regulations and other measures relating to it, but such regulations and measures are not in force till they are confirmed by the convocation. The convocation, which, besides the members appointed on the first establishment of the university, consists of all persons regularly admitted to the degrees of doctor in divinity, the civil law, and medicine, and to the degree of master of arts, confirms or rejects what is submitted to it by the senate, but has not the power to originate or amend.

Civil Engineering.

By the regulations of the university, provision has been made for a regular course of general education similar to that which is given at Oxford and Cambridge. The qualifications of the students are ascertained by examination before admission; and their proficiency during the continuance of the course is tested by public examinations held annually, particularly at the end of the third year for the degree of bachelor of arts, and at the end of the fourth year for the degree of master. Instruction in theology is likewise given; and those who at the end of the course pass the requisite examination, and produce the necessary testimonials, receive under the common seal of the university a certificate of competency and character, which is called a license in theology. In 1837, an important extension of the benefits of the university was made by the establishment of a course of instruction for students in civil engineering and mining, suggested by the extensive public works in the neighbourhood. The students in this department are examined, on admission, in the Latin language, in arithmetic, and the elements of mathematics. The full course of study extends over three years: the competency of the students is tested by a public examination at the end of each year; and those who have passed all the requisite examinations are admitted to the "academical rank" of civil engineer. Besides the regular courses of professional education, public lectures on various branches of literature and science are also delivered from time to time, which are open, under certain regulations, to persons who are not members of the university.

Fellowships, &c.

Six university fellowships have lately been endowed by the dean and chapter, which are open to any member who has passed the examination for the degree of B. A., and are tenable for six years. The fellowships are vacated by marriage, or by holding preferment, office, or property real or personal, producing L.300 a year or upwards. There are also twenty university scholarships of the annual value of L.30 each; and others founded by the trustees of the last two bishops. Prizes of various kinds are given for the encouragement of merit.

University College.

University College was formed at the opening of the university, for the purpose of uniting a system of domestic discipline and superintendence with academical instruction; and residence within the college is enforced on every student, unless a dispensation to reside elsewhere is granted by the warden. College examinations, independent of those appointed by the university, are held at the end of every term.

Degrees.

Degrees are conferred by the warden and convocation, but every grace for a degree must be allowed by the dean and chapter before it is proposed in convocation. The academical year consists of three terms, of not less than eight weeks each, called Michaelmas, Epiphany, and Easter. Michaelmas term commences not earlier than the 10th of October, and Easter term ends not later than the 30th June. No religious test is exacted till a student proceeds to his degree. For the terms and exercises requisite for proceeding to the different degrees, See *Durham University Calendar* for 1841.

SCOTISH UNIVERSITIES.

UNIVERSITY OF ST ANDREWS.

History.

At the beginning of the fifteenth century, Scotland contained no academical institution in which the higher branches of knowlege were taught. The Scotish youth who wished to obtain a more liberal education than the seminaries of the country afforded, were under the necessity of seeking it in foreign universities; in some of which colleges were early endowed for their reception. Soon after the middle of the thirteenth century, Dervorguilla, wife of John Balliol, founded and endowed a college at Oxford for Scotish students; and in 1326, the Scotish College in the university of Paris was founded and endowed for a similar purpose, by David Murray, bishop of Moray. The risk and inconvenience attending the removal of the youth to foreign schools was long felt; and the discerning part of the community were not insensible of the advantages which the country would derive from the establishment of an institution within its own limits, where the higher branches of education, in science, philosophy, and theology, might be attained. One of the individuals who entertained these sentiments was Henry Wardlaw, bishop of St Andrews, who took measures to remedy the evil. Having ascertained that his sovereign James I., at that time a prisoner in England, approved of his scheme, he resolved, with the consent and approbation of the estates of the kingdom,[1] to erect a university in the ecclesiastical metropolis. The lectures commenced in 1411; and the bishop, with the concurrence of the prior of St Andrews, and the archdeacon of Lothian, immediately granted to the masters and students the privileges belonging to a university. Benedict XIII. issued a bull of confirmation on the 27th of August 1413, instituting a *studium generale*, or university, for instruction in theology, the canon and civil law, medicine, and the liberal arts; and conveying to the bishop the power of conferring degrees in these faculties, thereby investing him with the power and dignity of chancellor. The pope on the same day signed other five bulls, securing the rights and privileges of the university, which were ratified by James I. in 1432.[2] The king at the same time granted to the members exemption from all the exigible tributes of his kingdom; an immunity which was confirmed by his four immediate successors.

The university was formed on the model of those of Paris and Bologna. The members, or *supposts*, as they were called, were divided into four nations, those of Fife, Angus, Lothian, and Albany, the last including all who did not belong to any of the other three districts. The supposts, at a congregation or general meeting, elected annually four procurators to watch over their interests, and four intrants, or electors, by whom the rector was chosen. The government was vested in the rector, of whom it was required as a necessary qualification, that he should be a graduate in one of the faculties, and should also be in holy orders. The university was represented in the rectorial court by twelve assessors, three selected from each nation. With the advice and consent of his assessors, the rector possessed supreme judicial power in all causes, civil and criminal, relating to members of the university, with the exception of crimes which inferred the highest punishment.[3] As in other cases which have already been mentioned, the privileges and powers possessed by the university excited the jealousy of the magistrates of the city; till a concordat was entered into by the contending parties, by which their respective jurisdictions were defined and adjusted.[4] The members of the university were divided into faculties, at the head of each of which was a dean, who presided at the meetings of the masters for regulating the course of study, for examinations, and the conferring of degrees. The university was well supplied with teachers even at its commencement. Before the papal bulls were issued, it included a professor of divinity, four lecturers on the canon law, and three who taught the arts or philosophy.[5] The revenues of the institution were at first extremely limited, and for some time consisted chiefly of small sums received from the students t their admission and graduation; but the persons appointd to conduct the different departments of study generally njoyed endowments from other sources. During the first wenty years of its existence, great inconvenience was sufered from the want of public buildings; and the schools vere held in the different religious houses, which in conequence claimed to be considered as constituent parts of ie university. In 1430 a *Pædagogium* was built for the chools of the faculty of arts, and for chambers for the stuents of that faculty; while the studies of the faculties of ieology and law continued to be conducted in other buildngs. The congregations of the university were held for t least 130 years in the Augustinian priory.[1]

[5] Fordun, as cited by Dr M'Crie, Life of Melville, i. 216.

The university was liberally patronised by James I. after is return from his long captivity in England; and being onducted by an active and devoted priesthood, it soon acuired the confidence and respect of the country, and tracted students from all parts of the kingdom. To proide more effectually for their instruction, James Kennedy, e successor of Wardlaw in the see of St Andrews, estalished in 1450 the College of St Salvator, which was nctioned by Pope Nicholas V. about the year 1455, and n favour of which new grants were made by the same relate, and by Pope Pius II. in 1458. The college was o consist of thirteen persons, all of whom were to live ithin its walls; a præpositus or provost, who was to be a octor of divinity; a licentiate and a bachelor of the me faculty; four masters of arts, and six poor scholars. he provost was required to lecture in theology once a eek, the licentiate twice, and the bachelor every *readble* day; the duty of preaching at stated times to the peoe being also imposed on the two former. Two of the asters of arts were to be annually chosen as regents, the ne to teach logic, and the other physics and metaphysics, ccording to the method of the schools and the statutes of e university. The masters of arts and poor scholars ere to be elected by the provost, licentiate, and bachelor. he benevolent founder granted as an endowment the ectorial tithes of four adjoining parishes, constituting the ree principal masters of the college rectors of three of em, and reserving the fruits of the fourth as a common nd for the maintenance and support of all members of the undation, together with their attendants and servants. bout the year 1468, Pope Paul II. in consideration of the sing reputation of the college, honoured it with the prilege of conferring degrees in theology and the arts; therey constituting it a separate university, though with limitd powers.

In 1512, John Hepburn, prior of the Augustinian moastery, and Alexander Stewart, archbishop of St Andrews, unded the College of St Leonard, which was in the same ear confirmed by a royal charter from James IV., accomanied, as in the case of the university, with an exempon to its members and property from all national imosts. The prior granted to this new erection the revenues the hospital of St Andrews, for the support of the prinpal master; four chaplains, two of whom were to be reents; six graduates in arts, who were to be diligent stuents of theology; and twenty scholars, students of philosohy. The principal, who was to be nominated by the prior, om the canons of the chapter, was constituted professor divinity, and was invested with absolute jurisdiction over l the members of the college. In conjunction with the rior, he was to appoint the regents; and candidates for the cholarships, after satisfactory examination by him, certied to the prior, were nominated by the latter, who was njoined to be influenced in the disposal of his patronage y merit alone, and not by individual solicitation. As in e case of St Salvator's, all the members were to live within the walls of the college, and were bound to conform to certain regulations as to dress, amusements, and general conduct. Delinquencies were to be severely punished; and the power of visiting the college and reforming its abuses was retained by the prior and the chapter of the convent.

St Andrews.

St Mary's College.

Notwithstanding the superior advantages of the two endowed colleges, there were still in the university professors and students who belonged to neither, and who continued to frequent the *Pædagogium*, although they were supported by but slender funds. The disadvantages to which they were subjected in their competition with the rival colleges induced Archbishop Alexander Stewart to make preparations for giving to the pædagogium a collegiate form, which were frustrated by his premature death in the field of Flodden. The design was resumed by his successor James Beaton, who in 1537 founded St Mary's College, or as it was sometimes called, the New College, and in the same year procured for it the confirmation of Paul III.[2] It was founded for all the faculties; and by its charter of erection, obtained the power of conferring degrees, thus forming a third independent university. But the college was not finally erected till 1553, when Archbishop Hamilton, under the authority of a papal bull obtained in the year preceding, extended its constitution, and endowed it with the tithes of six parishes. It was to consist of thirty-six persons; a prefect or principal, who was to be a doctor or licentiate in divinity, and who was to have jurisdiction over all members on the foundation; two professors of divinity, the one a licentiate and the other a bachelor; a professor of the canon law, who was to be in priest's orders; eight students of divinity, whose appointments were tenable for six years, and who, besides attending regularly the lectures of the professors, were themselves required to lecture; three professors or regents of philosophy, who were to teach logic, ethics, physics, mathematics, and the other liberal arts; a professor of rhetoric and one of grammar, who were to be masters of arts; sixteen poor scholars, students of philosophy, who were to be well acquainted with grammar and Latin; a provisor, a janitor, and a cook. The defence and increase of the Catholic faith being the declared object of the erection of this as well as the other colleges, the principal and professors had certain extra-academical duties assigned to them. The principal was required to lecture on the sacred Scriptures every Monday, the licentiate five times a week, and the canonist to deliver the same number of lectures on the canon law. Appropriate duties were assigned to the other members. The rector of the university, with the principal of St Salvator's College, and some of the highest ecclesiastics of the city, were to elect the principal and the professors of divinity and the canon law; and they again were to fill up all other vacancies as they occurred in the college. The rector was empowered to visit the college annually, and to see that discipline was duly enforced. The college was to be exempted from all public burdens. All vacations were to be disallowed, and absentees for a month in the year, without permission from the principal, were to forfeit their appointments. Nothing probably is more remarkable in the establishment of the colleges of St Andrews, than the success of the founders in obtaining for them the most celebrated teachers. Men who had distinguished themselves in the foreign universities were urgently invited as professors, and appear to have willingly embraced the opportunity to diffuse among their countrymen the learning which they had themselves acquired.

The constitutions of the colleges remained unaltered till the reformation, with the exception of the appointment of a professor of humanity in each of the colleges of St Salvator and St Leonard, answering to the professor of grammar in St Mary's. During the agitation of the religious controversy, the academical exercises were interrupted, and in the year 1559 the faculty of arts were under the necessity of discontinuing the public exhibitions usual at graduation.[1] Immediately after the establishment of the reformation, the laws and practice of the university were accommodated to the change which had taken place in the religious establishment of the country; but the mode of teaching, and the academical exercises, so far as related to philosophy and the arts, continued nearly on their former footing. The students who entered a college at the same time, formed a class, and were placed under the superintendence and tuition of a regent, by whom their studies were conducted during the whole course. The regular time of the course was four years, but it was more usually finished in three years and a half. The session commenced on the first of October, and continued till the end of July, the months of August and September[2] being allowed as a vacation. The regent assembled his class three hours every day, and read and explained to them the books of Aristotle, beginning with dialetics or logic, then advancing to ethics, next to physics, and concluding with metaphysics, which were considered the highest branch of philosophy, and mathematics, which included arithmetic. During their course the students were frequently exercised in disputations and declamations, both privately in their class, and publicly before the college and university. The principal frequently read lectures on the higher branches of philosophy, which were attended by all the students of the college.[3]

Course of study.

Degrees.

In the middle of the third year, the students who obtained from their regent and the principal of the college an attestation of regular attendance and good conduct, were allowed to propose themselves as candidates for the degree of bachelor. In the presence of three regents, annually selected from each college as examiners, the candidates *determined* a question in logic or morals, and answered such questions as were proposed to them on any of the branches of study with which they had been occupied. Those who acquitted themselves to the satisfaction of the examiners were confirmed *bachelors* by the dean, the rest were sent to a lower class. A similar form was observed in the act of laureation at the end of the course; except that on this occasion the candidates were examined on the whole circle of the arts, and were required to defend a thesis which had been previously affixed to the gates of the different colleges. They were then divided into classes, and their names arranged according to merit, with a certain preference to persons of rank. When the examinations were concluded, the degree of master of arts was solemnly conferred by the chancellor, *in nomine Patris, Filii, et Spiritus Sancti.* Certain fees were paid by the graduates, according to their rank, to the purser of the university and of the faculty, to the dean, and to other officers. Small annual fees seem originally to have been paid by the students to their regents.[4]

Soon after the establishment of the reformation, the leaders of that great revolution proposed a scheme for new-modelling the universities, which, though not adopted by the legislature, will remain a lasting monument of the enlightened and patriotic views of its compilers.[5] After several other ineffectual attempts, a commission was appointed in 1579, on the petition of the General Assembly, with full powers to consider the foundations in the university of St Andrews, to alter the constitution and form of study, and to introduce such improvements as might appear necessary. The commissioners, finding that all the colleges had departed from their original foundations, agreed upon a new form of instruction, which was laid before the ensuing meeting of parliament, and ratified on the 11th of November 1579. St Salvator's College was to consist of a principal, and four professors or regents of humanity and philosophy. The first regent was to teach the Greek grammar, and to exercise the students in Latin composition during the first, and in Greek during the second half year. The second regent, who was also considered a professor of humanity, was to teach the principles of rhetoric, and the practice of it as exemplified in the best Greek and Latin authors. This class was to spend an hour at least every day in composition; and during the last half year the students were to declaim once a month in Greek and Latin alternately. It was the duty of the third regent to teach, in the original language, part of the Logic of Aristotle, with the Ethics and Politics; and the Offices of Cicero in Latin. The fourth regent was to teach the necessary parts of the Physics, and the doctrine of the Sphere. Each regent was confined to his own department. Professors of mathematics and law were also established, who were to lecture at least four times every week; and the principal of the college was to act as professor of medicine. Similar arrangements were made in St Leonard's College; with this difference, that no classes of mathematics and law were established in it, and the principal was to lecture on the philosophy of Plato. St Mary's College was appropriated solely to the study of theology, and the languages connected with it. The course of study was to be completed in four years, under the instruction of a principal and four professors, each of the professors having under his care only the students of one year. It embraced, in the first year, the elements of Hebrew, Chaldee, and Syriac; during the next eighteen months, the same languages, with critical explanations of the Pentateuch and historical books of the Old Testament; and during the remaining eighteen months, the prophetical books were examined in the same manner. During the whole four years, the fourth professor was to explain the New Testament, by comparing the original with the Syrian version; and the principal was to lecture on systematic divinity. The students were required to attend the lectures of three professors every day during the continuance of their theological course. Such was the form of instruction drawn up by Melville, and recommended by Buchanan, which has been well characterised by Dr M'Crie as "the most liberal and enlightened plan of study which had yet been established in any European university."[6] This destination of the colleges continued till 1621, when, by an act of the legislature, their original constitutions were restored, "in all their heads, articles, and clauses," so far as was consistent with the reformed religion, with the single exception that St Mary's should be confined to the faculty of divinity. Professorships of mathematics and medicine were instituted in 1668 and 1721. We have not the means of ascertaining the precise number of students who belonged to the university at one time. In ordinary cases it appears not to have exceeded 200, and it did not fall much short of that number during the latter half of the sixteenth century. Fewer had attended it during the first half, and still fewer previously to that period.[7]

The three colleges continued without further alteration till the year 1747, when, in consequence of the inadequacy of the provision for the principals and professors of the two colleges of philosophy, a union of them was effected by parliamentary enactment, which enabled them to consolidate their endowments, and to make provision for a more extended course of instruction. By this statute the United College of St Salvator and St Leonard was to consist of a principal, a professor of Greek, three professors of philosophy, professors of humanity, civil history, mathematics, and medicine, and sixteen bursars on the original foundations. The same statute regulates the patronage of the professorships and bursaries, and makes provision for the disposal of the funds of the college. No change has since taken place in the constitution of the colleges, none of the suggestions of the royal commissioners appointed in 1826 having been carried into effect in any of the Scottish universities. The principal of United College takes no active part in teaching; the professor of ethics delivers a course of lectures on political economy, and the professor of medicine teaches chemistry and chemical pharmacy. In St Mary's College there is a principal, who is also primarius professor of divinity, and conducts the department of systematic theology; a professor of divinity, who confines his lectures chiefly to biblical criticism; and professors of ecclesiastical history and oriental languages. The members of the colleges have long ceased to live in common: the bursaries are still paid to certain poor scholars, but chambers are no longer provided for them, nor do they eat at a common table. The professors of United College receive fees from their pupils, but those of St Mary's have no remuneration except their salaries, and a small grant of public money.

The university consists of a chancellor, rector, two principals, and eleven professors. These members, with the exception of the chancellor, form the governing body of the university, under the name of the Academical Senate. The Chancellor is the highest dignitary in the university, and the guardian of its privileges. He was originally the fountain of honour, and entitled to confer all academical degrees; but this part of his official prerogative has long been in abeyance. According to the original charter, the bishop of the see, as in the other Scottish universities founded by

[7] Life of Melville, i. 250.

:clesiastics, was chancellor *ex officio*. Since the abolition of episɔpacy, he has been elected by the senate, is generally a noble-an, and retains his appointment for life.

The Rector, who is the next office-bearer, is elected, according the original constitution of the university, by four intrants ıosen by the four nations; the retiring rector having a casting ɔte in the case of an equality in the votes of the intrants. By the cisting regulations, the only individuals who are eligible are the vo principals, and the professors of divinity and ecclesiastical history. The rector nominates his substitutes and assessors from e senate, and with their advice determines all causes which are ought before him. He acts as a civil magistrate within the uniersity, and possesses over the students the power of expulsion.

The Dean of the faculty of arts is chosen annually by the memrs of the faculty, who are the principal and professors of United ɔllege. He presides in the meetings of the faculty, and commucates with the senate respecting applications for degrees.

The Senatus Academicus is composed of the principals and prossors of the two colleges, with the rector as president. By this ɔdy alone degrees are conferred; the faculty of arts merely exersing the privilege of recommending to it such individuals as they nsider entitled to that distinction. The senate also manages e university business, superintends the arrangements connected th the library, elects the chancellor, the professor of medicine, e librarian, and the archbeadle. An appeal to it is competent, certain cases, from judgments pronounced by either of the colges. All members of the senate, previously to their admission, ıst sign the Formula of the Church of Scotland, in presence of e presbytery of St Andrews.

In United College the Session or annual term of attendance for e Latin and Greek classes begins on or about the 20th of Octor; for the other classes, on the first Thursday of November, and ɔses on the last Friday of April. In St Mary's College, it commences about the end of November, and terminates in the beginng of April. In all the Scotish universities the curriculum of arts tends over four sessions; and at those of St Andrews, Glasgow, d Edinburgh, whatever other classes are attended, the Greek ıst be taken the first year, the logic the second, the moral phisophy the third, and the natural philosophy the fourth. At all ese seminaries, and also at the two Aberdeen colleges, it is usual the student to attend the junior Latin or humanity class along th the Greek; and these two branches form his whole occupan for that session. In his second session, at St Andrews, asgow, and Edinburgh, he enters the logic class; the lectures dered in which, at the two former universities, embrace the subt of rhetoric also. At Edinburgh, rhetoric is taught in a sepae class, attendance on which is likewise required from candies for degrees, but without any particular year being assigned it. In neither of the Aberdeen colleges is there any logic or etoric class. The other classes which it is customary to attend ring the second year are the senior Greek, the senior Latin, l the junior mathematics. In all the universities, except those Aberdeen, the class of moral philosophy is attended during the rd session, and natural philosophy in the fourth. Along with ese the students of the third year generally attend the senior thematics, and frequently the advanced Greek; those of the rth year continue to advance in their mathematical studies. both the Aberdeen colleges the class of natural philosophy is ended in the third year, and moral philosophy in the fourth. e qualifications required from candidates for graduation are ferent in the different universities; and in all, the professors the examiners, each in his own department.

At the beginning of each session, a code of laws is read by the ncipals to the students of their respective colleges, compliance th which is strictly enforced. Delinquents are first admonished vately by the principal, and, if the offence is repeated, are ought before the academical courts. The students of arts wear a ticular dress, which varies with the rank of the wearer, according he is a *primar*, *secondar*, or *ternar*. This dress was anciently worn all times when the student was out of his room, but is now disnsed with, except when he is within the walls of the college. e students of both colleges are required to attend divine worp every Sunday, except such as obtain dispensations from the principals and professors. The students of St Mary's assemble every morning in the public hall, for prayers, reading a portion of scripture, and singing psalms. The duty is performed by the students in rotation.

Revenue. The revenue of the university, as distinct from the colleges, is small, and is appropriated chiefly to the support of the library. The regular income for 1826 was L.297. The endowments of the colleges have been much curtailed within the last fifty years, by the augmentations of the stipends of those parishes, the tithes of which were granted to them by the original founders. The revenue of United College is derived partly from the funds of the original foundations, from royal grants made at different periods, from the donations of private individuals, and from property purchased by the college itself. In 1823, it amounted, including bursary funds, to L.3021. 1s. 6d. St Mary's College was originally endowed with tithes only, to which some additions were made by James VI. and William III. As in the case of United College, these have also been diminished by the sums which have at various times been allocated for the maintenance of the parochial clergy. The average income for the seven years preceding 1826 was L.1076. 5s. 5½d. The following table contains the different professorships, with the patronage, salary, and class-fees.

UNITED COLLEGE.

Office.	Salary.[1]	Class-Fee.		Patronage.
	L.	L.	s.	
Principal.	307	...		Crown.
Greek.	219	3	3	College.
Logic.	219	3	3	College.
Moral philosophy.	219	3	3	College.
Natural philosophy.	219	3	3	College.
Humanity.	199	3	3	Duchess of Portland.
Mathematics.	210	3	3	Crown.
Medicine.	199	3	3	University.
Civil history.	199	3	3	Marquis of Ailsa.

ST MARY'S COLLEGE.

Office.	Salary.			Patronage.
	L.	s.	d.	
Principal.[2]	238	8	2	Crown.
Divinity.	231	16	3	Crown.
Ecclesiastical history.	286	0	1	Crown.
Oriental languages.	211	0	1	Crown.

The funds and revenues of both colleges are managed by the principal and professors. The annual grants from the crown amount to L.525. The fees formerly exacted for degrees in arts have been abolished. Those payable for graduation in medicine are L.25. 16s. 11d.; and in divinity, when not conferred as an honorary mark of distinction, L.14.

Bursaries. In United College there are seventy-five bursaries, varying in amount from L.5 to L.25 each. Their aggregate value is about L.900. Twenty-two of these are open to general competition, eight are given by competition at Madras College, seven are assigned by the university and United College, and the rest by private patrons. St Mary's College possesses seventeen bursaries varying from L.7 to L.18. Their aggregate value is about L.200.

Number of students in session 1839–40, 145; Graduates in arts, 9; in divinity, 5; in medicine, 24; in law, 1.[3]

UNIVERSITY OF GLASGOW.

Foundation. In the year 1450, Pope Nicholas V., at the solicitation of William Turnbull, bishop of Glasgow, issued a bull, establishing a *studium generale*, or university, "for theology, the canon and civil law, the arts, and every other lawful faculty," at Glasgow; and granting to it all the rights and privileges belonging to the university of Bologna. The archbishop of Glasgow was constituted chancellor, with the same authority as was possessed by the heads of the Italian university, and particularly with the power of conferring degrees History. and licenses on candidates duly examined. No mention is made of medicine, as in the original erection of the university of St Andrews; but it is implied in the expression, "quavis alia licita facultate." In the following year a body of statutes for its government was prepared by the bishop and his chapter, which, with the papal bull, was confirmed in 1453 by a royal charter from James II. The king likewise exempted the members from taxes and all civic burdens; and in the same year various privileges were conferred by the bishop, similar to those granted by Bishop Wardlaw to the university of St Andrews.

---

[1] The salaries here given are those mentioned in the Report of the Royal Commissioners, as received in 1823. It being the practice of the ɔllege to divide every year nearly their whole revenue, the incomes of the members fluctuate considerably. In 1824 the salary of each was .35 more than in 1823.

[2] The principal has a house and a small garden; the three professors have each a garden, but no house.

[3] The number of students in all the Scotish universities has been much diminished within the last fifteen years. The diminution, we believe, s been produced by causes external to the universities themselves, and may be partly accounted for by the small inducements which the ırned professions hold out to young men in Scotland; by the superior advantages which are offered by the arts, manufactures, and comerce of the country; by the emigration of many young men who would otherwise have received a university education; and by the schools, iefly medical, which have been established in the principal towns of England and Ireland.

In the original constitution of the university, that of Bologna seems to have been imitated as far as circumstances would permit. It consisted of a chancellor, rector, deans of faculties, procurators, regents, masters, and scholars; and was placed by the bishops beyond the control of the civil magistrates. The supreme power was vested in the scholars who had been marticulated, and whose names remained on the *album;* and these, in their *comitia* or congregations, enacted, amended, or repealed the statutes. The *supposts,* or members of the university, were distributed into four nations,[1] each having a procurator, elected annually from its own number, who was invested with considerable trust and power. The supposts, assembled in *comitia,* also elected the rector through the medium of intrants, and at the same time chose four deputies to form the rectorial council. The rector, acting with the advice of his council, exercised supreme judicial and executive power over all the members of the university: he was invested with jurisdiction in all minor civil cases in which supposts were concerned; graver offences were specially reserved for the decision of the bishop himself. Permission was given to the supposts to bring their causes either before the rector or the bishop, and liberty of appeal to the latter was allowed to any one who thought himself aggrieved by the sentence of the former. In 1461 an ecclesiastical jurisdiction was conceded to the rector; and such a concession implies that this officer was always to be a person in holy orders. All houses and lodgings for the supposts within the city were subjected to regulations similar to those established by Gregory IX. in the university of Paris. The magistrates and other officers of the city took a yearly oath to observe and defend the privileges and liberties of the university.

This university, at its first erection, was entirely unendowed, and for a considerable time possessed no funds, with the exception of small perquisites paid at promotions to degrees. Its meetings were held in the chapter-house of the Blackfriars, or in the cathedral; and the teachers were furnished with schools in the religious houses. In 1458, the faculty of arts commenced building a *Pædagogium,* at the expense of its common purse; but this design was superseded by the liberality of the first Lord Hamilton, who in the following year conveyed to the principal and the other regents of the faculty, for their use and accommodation, a tenement in the High Street, together with four acres of land. The donor required that the principal and regents should, on their admission to office, promise on oath to commemorate himself and his wife as the *founders of the college.* The annals of the university furnish scarcely any information respecting the means of instruction which it provided, and the mode in which that instruction was conveyed. In the higher faculties, the teaching seems to have been confined to occasional lectures. More attention appears to have been paid to the inferior branches of science. The records mention the admission of a regent of philosophy within two years after the erection of the university. It may readily be assumed that the want of salaries to the professors was the principal reason why the higher branches of knowledge were neglected; and even the instruction which the university diffused was furnished by men who derived their emoluments from other sources. The professors of divinity, and of the canon and civil law, depended for their support on the benefices which they held as ecclesiastics in various parts of the country.

By Lord Hamilton's deed of bequest, the faculty of arts obtained the nucleus of the college property; but it is not quite clear that the name of a college was then, for the first time, conferred upon it. Two sets of records are preserved, commencing with the origin of the university, one volume of which is entitled "Annales *Collegii Facultatis Artium* in Universitate Glasguensi;" and if this title was prefixed to it so early as 1451, the college must have existed as a corporate faculty before the charter of Lord Hamilton. It is not however till 1462 that express mention is made of the *Collegium Facultatis Artium;* and it may be questioned if even at that time the college was co-extensive with the faculty, and not rather a select body, which assumed the government of the whole faculty, like the colleges of faculties at Bologna. The exact imitation of all the customs of Bologna makes the latter supposition probable. It is at least clear that at this early period the term college had no reference to a building for common habitation or common maintenance.[2]

The university remained in this state for about a hundred years, during which time it appears, from the language of certain grants, that the university and the college of the faculty of arts were frequently confounded. In the year 1557, two years before the reformation, James Beaton, archbishop of Glasgow, conveyed to the *Pædagogium,* or *university,* and to the masters and regents in the same, an ecclesiastical benefice, which, from the accompanying restrictions, was clearly intended for the benefit of the whole university. Similar instances might be adduced. At what precise period the two terms ceased to be used synonymously, and the existence of a separate college to be recognised, does not appear.

From its peculiar constitution, the university of Glasgow suffered more from the change of religion at the reformation than the other learned seminaries of Scotland. The professors in the higher faculties being all supported by their livings in the church, and adhering to the old religion, successors could not be appointed to them, owing to the total want of salaries. It likewise suffered materially from the fraudulent alienation and unjust seizure of its slender revenues.[3] This evil was in some degree remedied in 1563 by Queen Mary, who granted certain houses and lands for the benefit of the college or university, and specially for the maintenance of five bursars. In 1572 the magistrates of Glasgow granted a charter, which was confirmed by act of parliament, conveying to the college certain church property for the support of a professor of divinity, who was to be principal or provost, two regents of philosophy, and twelve poor students. The regents and students were

---

[1] The four nations were, *Natio Clydesdaliæ,* comprehending the natives of Lanarkshire, Renfrew, and Dunbarton, from Erickstane, the source of the Clyde, to Dunbarton; *Natio Thevidaliæ,* including the Lothians, Stirling, and all the towns east of the river Urr; *Natio Albaniæ,* embracing all the country north of the Forth; and *Natio Rothsaiæ,* including Ayrshire, Galloway, Argyle, with the Isles, Lennox, and Ireland.

[3] M'Crie's Life of Melville, i. 70.

ɔ eat and sleep within the college, and were required to sign
ıe Confession of Faith. It might be supposed that these
ifts would have been sufficient to place the college on a
spectable footing; but it appears that even then the whole
ınds did not exceed L.300 Scots, or L.25 sterling.

Five years afterwards, James VI. new-modelled the constitu-
on, and made a very considerable addition to the revenue. The
ıarter then granted forms the basis of the present constitution,
ıd is known by the name of *Nova Erectio*. According to it, the
llege was to consist of a principal and three regents, to each of
hom certain salaries were assigned, four poor students, and ser-
nts. The principal, who was to have the ordinary jurisdiction
er the members of the college, and to reside there constantly,
ıs to be a proficient in sacred learning, and was required to lec-
re at least one hour a day for five days in the week. He was to
nominated by the king; and failing an appointment by the
ɔwn within thirty days, the election devolved upon the chancel-
, rector, dean of faculty, and five clergymen, including the mi-
ster of Glasgow. The regents were to be elected by the rector,
an, and principal, and were appointed each to a particular de-
rtment of learning, a principle which had never before been
ɔpted in Scotland, instead of conducting the students through
the branches of instruction included in the course. The elec-
s were invested with a visitorial power over the regents, and
ght remove them. The principal, if negligent after three ad-
nitions, was removable by the rector, dean, and regents. The
tor, dean, and minister of Glasgow were to inspect and audit
accounts four times in the year, and to direct the surplus re-
ıue to be applied to the necessary uses of the college. It is ob-
ɔus that the intention of this charter was to place the college
der the effectual superintendence of the university. In 1581,
chbishop Boyd granted to the college an additional endowment
the support of a fourth regent, who is believed to have been
professor of Greek. About the same time a new body of sta-
es was framed by royal authority, which still regulates both
university and college.

The course of instruction prescribed by the *Nova Erectio* is an
litional proof of the enlightened views entertained by the early
ders of the Church of Scotland on the subject of public educa-
n; but having already alluded to this subject in connection with
university of St Andrews, our limits will not permit us to give
n detail. It may be sufficient to say, that it embraced every im-
ɔvement which the learning and experience of Andrew Melville
l been able to devise. Small fees, varying with the rank and
nding of the students, were to be paid at matriculation to the
tor and beadle. New students, as well as those who had attend-
the former year, were to be examined in the beginning of Oc-
ıer; and the examination of candidates for the degree of master
arts was to be held on the third week of August. After due
ımination, the dean and others were to decide on the qualifica-
ns of the several candidates, and to arrange their names ac-
ding to merit. The examiners were to be the dean, principal,
ɔfessors, and the master of the grammar-school, all of whom were
ɔrn to be faithful and impartial. Degrees were to be solemnly
ıferred by the chancellor. *Honoraria* were to be paid to the re-
ıts, according to the rank and fortune of the students. Sons
the nobility and barons of Scotland were to pay annually at
st L.3; those of the second rank, who, though inferior to the
ons, possessed means sufficiently ample, were to pay L.2;
ɔse of the third rank to pay L.1; the poor were to be admitted
e of all charge.

The constitution founded on the *Nova Erectio* has at different
ıes been extended and improved by commissions of visita-
n. One appointed by the General Assembly in 1639, and re-
wed in subsequent years, recognised, in 1640, a class of hu-
nity, and instituted a separate professorship of divinity. In
42, another professorship of divinity was established by the
iversity, and distinct departments of study were assigned to the
ncipal and the other two professors of this branch. A profes-
ship of medicine, which had existed for some time, was de-
red to be unnecessary. By the same commission, strict regu-
ions were made respecting the study of Greek and Latin, the
rformance of public exercises, and the regularity of attendance.
ıe most material change effected on the constitution of James
. was this: "on the understanding that it was a disadvantage
students to change their masters annually, it was required that
ery master, instead of continuing to teach the same branch,
should educate his own scholars through all the four classes;"[1] four years being the curriculum necessary for graduation in arts.

In 1727 a royal visitation made several important regulations, which have ever since remained in force. It declared the right of electing a rector to be in all the matriculated members, moderators, or masters and students; revised the system of teaching introduced by the charter of *Nova Erectio;* and assigned permanent professors to the three classes of philosophy. The *Semi* Class was set apart for logic and metaphysics, the *Bachelor* Class for moral philosophy and natural philosophy, and the *Magistrand* Class for physics and experimental philosophy. Besides the professors of humanity, Greek, and philosophy, the visitation recognised professors of divinity, law, medicine, botany, anatomy, oriental languages, mathematics, and history, requiring them to teach whenever five or more scholars presented themselves. The same commission defined the powers of the faculty meetings, and sanctioned certain privileges "which had been assumed by them in contradiction to the statutes, and which by this time had passed into usages. As the meetings of the faculty were composed only of professors, this interpretation tended to give the college greater power of self-government, and to remove it from the control of the officers of the university."[2]

The exclusive rights thus granted to the college were submitted to the Court of Session in the years 1771 and 1772. The court declared that the whole revenue and property of the college are vested in the principal and masters, and are not subject to the control of the rector and his assessors. At the same time it recognised the visitors appointed by the charter of foundation, and their right to audit the college accounts, and to dispose of the surplus revenue. The right of election to professorships, which the charter intrusted to the rector, dean, and principal, was found to be in the rector, dean, and faculty meeting, or, in other words, in the professors themselves. The distinctive privilege of professors of the university, and of the college of Glasgow, was finally made in 1807, in a lawsuit which arose out of the appointment of a regius professor of natural history. The incumbent claimed a right to participate in all the powers and privileges of the faculty, and to be admitted as a member of the college, which was resisted by that body. The Court of Session recognised the rank of the incumbent as a professor in the university, but decreed that he was not a member of the college, and not entitled to share its property, or to vote in any of its meetings. This decision was acquiesced in by the crown; and, in all subsequent appointments to regius professorships, restrictions have been introduced which are intended to be in conformity with the deliverance of the court.

Present Constitution.

The university at present consists of a chancellor, rector, dean of faculty, principal, professors, and students. The business of the university is transacted in three distinct meetings; those of the Senate (*Senatus Academicus*), the Comitia or general Congregation, and the Faculty. The *Senate* consists of the rector, dean, members of faculty, and the other professors. In this meeting the rector presides, except when affairs are managed for which the dean is competent. Meetings of the senate are held for the election and admission of the chancellor and dean of faculty, the vice-chancellor and vice-rector, for electing a representative to the General Assembly, for conferring degrees, for the management of the libraries, and other matters belonging to the university. The constituent members of the *Comitia* are, the rector, dean, principal, professors, and the matriculated students of the university. In this meeting the rector or vice-rector presides. Meetings of the *comitia* are held for the election and admission of the rector, for hearing public disputations in any of the faculties previously to the conferring of degrees, for the admission of professors, and for promulgating the laws and other acts of the university and college courts. The *Meeting of Faculty*, or *College Meeting*, consists of the principal and professors of divinity, ecclesiastical history, oriental languages, natural philosophy, moral philosophy, mathematics, logic, Greek, humanity, civil law, medicine, anatomy, and practical astronomy. In this meeting the principal presides, and has a *casting*, but not a *deliberative* vote. The members of the faculty have the administration of the whole revenue and property of the college, with the exception of a few particular bequests, in which the rector and other officers of the university are specially named. Along with the rector and dean, they exercise the patronage of eight professorships, which is vested in the college.[3]

Chancellor.

The Chancellor, who is the highest officer in the university, is elected by the senate. As at St Andrews, he is usually a nobleman, and he holds his appointment for life. The chancellor nomi-

---

This mode of conducting academical education was long followed in all the universities of Scotland; and, chiefly from the influence of Dr
id, who gave it a decided preference, continued to prevail at Aberdeen till 1800. Commissioners' Report, p. 221.

Malden, p. 159.

[3] New Statistical Account of Scotland, No. vii. p. 173.

nates a deputy or vice-chancellor, and by himself or deputy has the sole privilege of conferring degrees on persons found qualified by the senate.

Rector. The Rector is elected by the comitia, divided into nations, according to the act of visitation in 1727. This office in ancient times was invariably held by a clergyman; and it was not till 1717 that the royal commission ordered that the rector should not be a minister, nor bear any other office in the university. By the statutes, the rector is an annual magistrate; but it has long been customary to re-elect the same person for a second year. His duties were formerly important; but the practice of electing men distinguished in literature and politics, who are non-resident, has led to the remiss and inefficient discharge of them. The rector nominates a vice-rector, generally a professor, who in his absence is entitled to preside in the senate and comitia, and to exercise the other duties of the office, with the exception of the visitorial power.

Dean of Faculties. The Dean of Faculties is elected by the senate, and generally holds his office for two years. He is entitled to exercise a superintendence over the studies, and, in conjunction with the masters, to judge of the qualifications of candidates for degrees.

Principal. The Principal, who must be a minister of the church of Scotland, is appointed by the crown. In right of his office he is primarius professor of divinity; but the duty of teaching has long been discontinued. He is the head of the college, presides in all meetings of the faculty, and exercises the ordinary superintendence of the deportment of all members of the university.

Subordinate Officers. The other officers are, a Factor, appointed by the college to collect the revenue, keep accounts, &c., who must not be principal, a professor, or master, in the university; a librarian, janitor, beadle, &c.

Faculties. In the original foundation, the Faculties of theology, the canon law, the civil law, and the arts, are expressly enumerated; and medicine and music, though not specified, are implied. Soon after the erection of the university, some efforts were made to teach the canon and civil law, and professors of divinity are occasionally mentioned; but till the reformation there seems to have been no regular course of instruction, except in the faculty of arts. The university now contains four faculties; those of arts, theology, law, and medicine. The faculty of law is confined to the single professor of the civil law; the other faculties have the usual complement of professors. The professors of Greek, logic, moral and natural philosophy, whose chairs were earliest endowed, are denominated regents, and enjoy, in right of their regency, certain trifling privileges. The regius professors, whose chairs have been recently founded and endowed by the crown, are members of the senate only, and not of the faculty of the college.

Revenue. The Revenues of the university and college are derived from estates, tithes, and bequests, and, with some unimportant exceptions, are administered by the principal and professors of the college, under the control of the ordinary visitors. The *gross* revenue, including royal grants, which together make L.510, amounted in 1824 to L.9916. 18s. 3d. From this fund the principal and thirteen faculty professors receive their salaries; the others are endowed by grants from the crown.

Connected with the college are twenty-nine foundations for Bursaries, whose benefit extends to about sixty-five students. Their average annual value is L.1165. 10s. 4d.; the highest being L.50, and the lowest L.4. 10s.; and they are tenable for periods varying from three to eight years. Besides the bursaries, the principal and professors of the college possess the right of nominating students, natives of Scotland, who have attended two sessions at the university of Glasgow, or one session there and two at some other Scottish university, to ten exhibitions at Balliol College, Oxford, on the foundation of John Snell. Each exhibition is of the yearly value of L.132, and lasts for ten years. Another foundation, by John Warner, bishop of Rochester, of L.20 a year, to each of four Scottish students at the same college, during their residence at Oxford, is generally given to the Glasgow exhibitioners; so that four of them have an income of L.152. Warner's exhibitions are in the gift of the archbishop of Canterbury and the bishop of Rochester, who usually nominate on the recommendation of the master of Balliol College.

The Session commences on the 10th of October, and ends in the beginning of May. The only lectures delivered in summer are those of the professor of botany, whose course continues from the 20th of April till the 20th of July.

Students in the faculty of arts may enter either the humanity or Greek class, and must proceed regularly to the logic, moral philosophy, and natural philosophy, in order to their obtaining degrees, or being admitted to the classes of divinity. Such as are not natives of Scotland may enter the logic class in the first year if found qualified. There is no examination previously to admission; but soon after the commencement of the session, the students of Greek, logic, moral and natural philosophy, are publicly examined on the subject of their studies in the preceding year. This is called the *Blackstone Examination*, and takes place in presence of the principal, the professor whose class is proposed to be entered, and of all others who choose to attend.

The ordinary academical Discipline is conducted by the principal and the five professors of the Gown classes, viz. the professors of humanity, Greek, logic, moral and natural philosophy, who meet with the students on the Saturdays in the common hall, and take cognizance of all petty delinquencies. Punishments are inflicted by admonition, fine, and sometimes by extra exercises. Cases of a graver character are brought before the faculty and rectorial court, whose jurisdiction extends even to expulsion. The professors are at due pains to enforce regular attendance, and to stimulate the industry of the students. All students, except those who obtain dispensations, are required to attend divine worship every Sunday in the college chapel. The students of languages and philosophy wear gowns of scarlet cloth or frieze.

The number of students in session 1839-40 was 940; Graduates in arts, 28; in medicine, 66; in surgery, 13; in divinity, 6; in law, 2. The fees for graduation in arts are L.3. 1s.; in divinity, L.20; in medicine, L.25. 3s.; for LL. B. L.10, and for LL. D. L.20.

The following table contains a list of the professorships, with the date of their foundation, the patronage, the salary attached to each, and the fees exigible by the professors.

		Founded.	Salary.	Fees.	Patronage.
	Principal	1577	L.450 11 11½	... ...	Crown.
Faculty professorships.	Logic and rhetoric	1577	289 6 6	L.3 3 0	Faculty, rector, and dean.
	Moral philosophy	1577	286 11 0½	3 3 0	Faculty, rector, and dean.
	Natural philosophy	1577	291 2 1	4 4 0	Faculty, rector, and dean.
	Greek	1581	289 8 10	3 3 0	Faculty, rector, and dean.
	Divinity	1630	425 10 7½	2 2 0	Faculty, rector, and dean.
	Humanity	1637	289 8 11	3 3 0	Faculty, rector, and dean.
	Mathematics	1691	292 0 0	3 3 0	Faculty, rector, and dean.
	Oriental languages	1709	300 0 0½	2 2 0	Faculty, rector, and dean.
	Theory and practice of medicine	1713	270 0 0	3 3 0	Crown.
	Civil law	1713	310 0 0	5 5 0	Crown.

w.

The fee here given in the Greek class is that for the public c s. The fee for the private class is L.1. 1s., and attendance is fi e after two sessions. The fee for private students in the nat al philosophy class is L.3. 3s., and for the experimental course L. 2s. The professor of natural history has a class of mineralo y, the fee for which is L.1. 10s. 6d. The fee for the class of S tish law, which is taught by the professor of the civil law, is L.4. 4 Part of the salaries of the principal and the professors of div ty is payable in grain, and varies with the price of that artic . Several of the professors receive part of the graduation fe . The principal and thirteen professors occupy houses erecte by the college: the expense of keeping them in repair, the t es, and civic burdens being also defrayed out of the college f ds.

UNIVERSITY OF ABERDEEN.

The university of Aberdeen was founded in 1494, by a b l of Pope Alexander VI., issued on the representation o James IV., who was desirous to extend the advantages o education to the northern districts of his kingdom. The papal edict authorized the erection of a *studium gen ale et universitas studii generalis*, in the city of Aberd n, for teaching divinity, the canon and civil law, med ine, and the liberal arts; and conferred upon it all the p ileges and immunities which were enjoyed by the univ sities of Paris and Bologna. The university was to c sist of a chancellor, who was to be the bishop of Aberd n, a rector, and doctors of faculties, and was invested w h the power of conferring degrees, which were to be c sidered valid throughout Christendom. Two years after, o the publication of the deed of erection, the king granted a harter in favour of the university, bestowing upon it c tain ecclesiastical funds for the support of its members, a d communicating to it all the rights, liberties, and adv tages which his ancestors had given to St Andrews and G sgow. Its privileges were finally established by a pap bull issued in 1500. In erecting this new seminary, the m del of Paris seems to have been mainly followed. The s posts were divided into four nations, who seem to have e cted their procurators (*procuratores gentium*); but they t k no further part in elections, or in the government of t university, the procurators acting as their representat es.

of
ity,
s

In 1505, William Elphinstone, bishop of the diocese, for t purpose of increasing the revenues of the new univers y, and enlarging the number of its members, founded and e dowed a college in honour of the Trinity and the Virgin M ry, which was in the following year confirmed by the h d of the church, and soon after by the reigning monarch. T e college was to consist of thirty-six ordinary members, t chief of whom was to be a doctor or licentiate of div ity, who was to be styled principal, and to whom all the m mbers were to yield obedience. Next to him were doct s and licentiates of the canon and civil law and medicine; a master of arts, who was to be regent and sub-principal; and a other who was to teach the elements of literature. Besides t se there were five masters of arts, students of divinity, w o were to retain their appointments for a limited number o years, and thirteen poor scholars of respectable talents a d proficiency, who were to be students of arts. All the m mbers, with the exception of the doctor of medicine, w re to be ecclesiastics, and were required to live within e college. The rector of the university, if not a member o the college, and if he was, the dean of the faculty of a s, and the official of Aberdeen, were constituted visitors, h power to remedy whatever was found defective.

A new erection was prepared by the bishop, and offic lly published in 1531, increasing the number of the embers of the college, improving their comforts, and in ducing a more efficient system of instruction. By this w charter, which, though modified by time and circumstances, still regulates, in a great degree, the form and practice of the university, the members of the seminary were to be forty-two. The first class consisted of four doctors; a doctor of divinity, who was to be principal, and whom all the other members were respectfully to obey; and doctors of the canon and civil law, and medicine, or licentiates if doctors could not be found. In the second class were eight masters of arts, the first of whom, skilled in philosophy and the arts, was to be sub-principal; the second was to be conversant in poetry, grammar, and rhetoric; and the other six, from whom the regents were to be elected, were to be students of divinity, and to retain their appointments for six years. The next class was formed of students of law, who were to study the civil law, and to attend the lectures delivered on that subject. All these, with the exception of the doctor of medicine, were to belong to the priesthood, and were occasionally to say mass for the founders. There were, besides, thirteen students of arts, retaining their endowments for three years and a half, the usual curriculum in that faculty; and eight prebendaries, who were to attend to sacred music, one of them being styled Cantor, and another Sacrist, and six boys for the choir. For all these accommodation was to be provided in the college. The revenues were placed under the charge of a procurator or factor, who was to be appointed by the principal officers of the college.

Aberdeen.

The principal was to be elected by the rector of the university, the procurators, doctors, sub-principal, regents of arts, humanist, theological students, cantor, and sacrist, and to be admitted by the chancellor. His duties were to govern the college, to preside in its meetings, to direct the regents in the delivery of their lectures, and to punish such as were deficient in their duty, to profess every day in philosophy and the arts, and to give lectures in divinity to the people six days in the year. The doctors, who were to be appointed by nearly the same electors, were likewise to be admitted by the chancellor, and to lecture to the students, each on the subjects belonging to his faculty. The election and admission of the sub-principal and humanist were to be conducted in a similar manner. The former was required to lecture in philosophy and the arts *quolibet legibili die*, to instruct the students in manners and virtue, to preside at public disputations among the students, to inflict fines on such as absented themselves from divine worship, and, along with the principal, to take a general superintendence of the affairs of the college. The students of theology and the arts were to be elected by the sub-principal, the regents, and the doctors of faculties, and admitted by the principal. The theological students were required to apply themselves to the study of their science, and to be qualified within three years to take their bachelor's degree. Their places, when vacant, were to be filled up from the students of arts. The college was exempted from all civic burdens.

From this statement it appears that the northern seminary closely resembled in its constitution the colleges of St Andrews and Glasgow. The connection between the college and the university is distinctly marked in the charter of foundation, in which it is recommended that the permanent and higher offices should be supplied from the inferior members if they were qualified, if not, from the members of the university of Aberdeen; and failing these, recourse was to be had to other universities. As at Oxford, Cambridge, and St Andrews, however, the university has disappeared, and the incorporated and endowed college only remains. The college is co-extensive with the university, or rather the university is confined to the limits of the college; nor is any distinction between them preserved, as at Glasgow.

This college remained in nearly the same state for more than a century, without however escaping the deterioration which seems to be incident to all exclusive bodies. In 1619 Bishop Forbes obtained a commission of visitation, by which the abuses that had gradually been engendered were reformed, and the original foundation, with some exceptions, restored. By the introduction of the reformed religion, some of the offices were rendered unnecessary; and accordingly the General Assembly, in 1639, ordered those of the canonist and cantor to be abolished. After the abolition of episcopacy, Charles I. resolved to apply part of the revenues of the different sees to the support of the universities, and appointed a commission to inquire into the state of those of Old and New Aberdeen; the result of which was his executing a charter, uniting them as one university, under the name of "King Charles's University of Aberdeen." The colleges however continued distinct, and are separately recognised in the act of 1641, by which the grant of the rents of the bishopric of Aberdeen was ratified; nor do they appear ever to have acted together as one university. Bishop Elphinstone's seminary has since retained the name of King's College. Another attempt to form both into one university was made about the year 1784, which after long negociation and discussion was abandoned; and a similar result is likely to attend the labours of the commission appointed in 1836 and 1837.

From the period of its institution down to the earlier part of the last century, various improvements were introduced by royal and parliamentary commissions. The General Assembly also extended its jurisdiction to the college; and the chancellor of the university and the ordinary visitors appear to have watched over its interests. In what manner the rector and his assessors were elected, and how frequently their visitations took place, are unknown for a period of 129 years after the institution of the college. Subsequently this court appears to have been efficient, and to have been instrumental, in several instances, in giving effect to improved plans of education. The senate, consisting of the regular officers of the college, likewise applied themselves to the same laudable object, and from time to time introduced such alterations as a change of circumstances or the advancement of knowledge rendered necessary. About the year 1620 a professorship of divinity was instituted by the college, and was confirmed two years after by royal charter. Weekly discourses on catechetical doctrine were established; and in 1764 a professorship of oriental languages was founded, for which an endowment out of the bishops' rents was afterwards obtained. In 1753 the teaching of the elements of Latin was abolished, and the scholarship of the class raised to the standard of the other universities. In the same year, the senate, taking into consideration the whole state of the college, approved of certain statutes intended to regulate the length of the session, the management of the bursaries, and the plan of instruction. On this last head, after mature deliberation, it was determined, chiefly, it is alleged, through the influence of the celebrated Dr Reid, who was at that time one of the regents, that the old system of the same regent conducting the students through the whole course should be continued, as at once more beneficial to the students, and more advantageous to the cause of literature and science. And it is a curious fact, that the system thus sanctioned by high authority prevailed till the year 1800, when the practice of the other universities was here introduced.

Constitution.

The university and college at present consist of a chancellor, rector, principal, sub-principal, and nine professors; the office of sub-principal being always held by one of the professors. The college contains the four faculties, and, as at St Andrews and Glasgow, the senate, besides managing the business of the college, and administering the revenues, exercises the patronage of certain academical offices. The chancellor and rector are appointed by the senate. The office of the rector is annual: his four assessors, who constitute his court, are elected by the senate at the same time with himself. The *procuratores gentium* are called into existence only for the purpose of assisting in the election of certain office-bearers, and are then appointed by the senate. The office of dean of faculty has also fallen into desuetude, excepting in the case of a vacancy in the professorship of divinity, when a dean of the faculty of divinity is chosen by the senate, he being by the charter nominated one of the electors. The principal and sub-principal are elected by the rector, procurators, and professors, and admitted by the chancellor. The principal presides in the meetings of the college, but has long ceased to take any part in academical instruction. The sub-principal presides in the meetings of the faculty of arts, and, in the absence of the principal, in the meetings of the senate, and collects the fines imposed on the students for any breach of discipline.

The Revenue of the college arises from certain properties acquired under the foundation charters, from others obtained subsequent to the dates of these charters, and from royal grants. A great part of the original grants consisted of tithes, which, being subject to the burden of supporting the parochial clergy, have been much diminished. The total nett revenue for 1836 amounted to L.2364, the royal grants being L.1148. 6s. 8d. King's College possesses thirty-two foundations for bursaries, the benefit of which is extended to 134 students. Their aggregate value amounts to L.1771. 13s. 10d., and they vary from L.50 to L.5 and under. About eighty of these are open to public competition. The bursars are required to attend the junior humanity and Greek classes during the first session, and at the commencement of the following session are examined as to the proficiency which they have made in these languages during the vacation. They are also admitted to all the classes on the payment of modified fees in proportion to the amount of their bursaries.

The Session commences on the first Monday of November, the previous week being employed in deciding, by comparative trial, the vacant bursaries in the gift of the college, and in ascertaining the attainments of the bursars presented by private patrons. It terminates at the end of twenty-one weeks. It has long ceased to be the practice of the students to live within the walls of the college; and the discipline of the professors is therefore chiefly confined to the class-room. Strict attendance is enforced, and various methods are adopted to fix the attention of the students on the subjects of study. The regular fees exigible from the students who do not hold bursaries are, for the classes of Greek, mathematics, moral and natural philosophy, L.3. 3s.; first humanity and second Greek classes, 10s.; second humanity class, 15s.; chemistry and natural history, L.1. 11s. 6d.; oriental languages, L.1. 11s. 6d.; civil law, L.1. 1s. These fees are modified, in the case of bursars, in proportion to the amount of the bursaries. An academical dress is prescribed by the charter of foundation, and is still imperative on all students except those of medicine and divinity. The students are required to attend the college chapel; but a dispensation is granted to all who produce a written request from their parents or guardians.

The number of students in 1839-40 was 350;[1] Graduates in arts, 36; in divinity, 1; in law, 2; in medicine, 8.

The following table contains a list of the professorships, with the date of their foundation, the patronage, and total emoluments of the professors, for the year 1836.[2]

Office.	Founded.	Emoluments.			Patrons.
		L.	s.	d.	
Principal	1505	300	8	7	Rector, procuratores gentium, professors.
Professorship of Greek	1505	474	3	8	Rector, procuratores gentium, senate.
Humanity [chemistry and natural history].	1505	450	9	6	Rector, procuratores gentium, senate.
Mathematics	1505	355	6	1	Senate.
Natural philosophy	1505	360	12	1	Senate.
Moral philosophy	1505	377	18	0	Senate.
Medicine	1505	211	7	3	Rector, procuratores gentium, senate.
Civil law	1505	214	9	3	Rector, procuratores gentium, senate.
Divinity	1620	425	8	10	Synod of Aberdeen, principal, dean of faculty of divinity.
Oriental languages	1674	242	11	0	Crown.

The principal, sub-principal, with the professors of humanity, mathematics, natural and moral philosophy, and divinity, have, besides, houses and gardens.

Besides the professors, lecturers have been established in connection with the college, who teach the following branches: practical religion, evidences and principles of the Christian religion,

---

[1] The students of divinity, who amounted to 91, and a few of the students of medicine, were common to King's and to Marischal College.

leen. ateria medica, anatomy and physiology, surgery, practice of me-
icine, midwifery, institutes of medicine, medical jurisprudence,
d botany. With the exception of the first, the lecturers are
l appointed by the senate.

MARISCHAL COLLEGE.

hal
e.

Marischal College, in New Aberdeen, was founded by
e Earl Marischal, under royal authority, in 1593 ; and in
e same month received the sanction of the General As-
nbly. In July following it was ratified by an act of par-
ment, which granted to it all the privileges and jurisdic-
n appertaining to any free college within the realm, but,
ntrary to the ancient practice, subjected all its members
the jurisdiction of the magistrates of the city, in all things
ne or committed by them beyond the walls of the col-
ge. The college was denominated an *Academy*, or *Se-*
nary of Learning, and was to consist of a chancellor,
ctor, dean of faculty, principal, three regents, six alum-
and two inferior persons to manage the internal af-
rs of the seminary. The principal was to superintend the
ole establishment, and to exercise jurisdiction over all its
mbers ; being invested with the power of censuring the
gents, and of expelling them from the college, with the
ncurrence of the rector and dean, after three admoni-
ns. He was to be well instructed in sacred literature
l in the learned languages, particularly in Hebrew and
riac, and was required occasionally to teach divinity,
atomy, physiology, the principles of geography, chrono-
y, and astronomy, and the elements of Hebrew grammar
l construction ; duties presupposing an extent of acquire-
nt which the founder would have some difficulty in ob-
ning. He was also invested with the power of conferring
grees in arts on such as he deemed worthy of the dis-
ction. The first regent was required to teach the
ments of arithmetic and geometry, and the sciences of
ics and politics ; the second was to teach the principles of
ic, and to exercise the students in writing and declaim-
in Latin and Greek ; and the third, who was the low-
, was appointed to teach Greek, combining with it, dur-
the first six months, Latin composition, afterwards the
ting of Greek, and adding a short account of the ele-
ntary principles of logic. It thus appears that, from the
nmencement of the college, the regents had particular
fessions assigned to them ; and it was expressly ordained
t no regent should undertake a new professorship. The
rl Marischal reserved to himself and his heirs the patro-
ge of the professorships ; the examination and admis-
n of the persons nominated being vested in the chancel-
if he were a clergyman, the rector, dean, the principal
King's College, and three clergymen, including the mi-
ter of Aberdeen. By the forfeiture of the Marischal fa-
y, the patronage devolved upon the crown. The elec-
of the bursars was likewise retained by the founder,
l their admission vested in the members of the college.
vacation was allowed ; and, that the members of the
lege might devote themselves exclusively to their respec-
duties, they were prohibited from holding any public
ce, and even from acting as rector or dean of faculty.

The chancellor, rector, and dean, were instructed to visit
college three times a year, for the purpose of correcting
atever might be wrong in doctrine or discipline. The
tor was to be elected by all the students, through the
dium of procurators appointed by them when divided
four nations, to have jurisdiction over the college,
l to preside in its meetings, after taking the oath of of-
. The dean of faculty was to be elected by the senate
l the minister of Aberdeen ; his duties being to preside
examinations, to administer the oath of fidelity to the
miners, and to take cognizance of the doctrine and dili-
nce of the regents. He was invested with all the privileges belonging to the dean of faculty at St Andrews, or in any other university. A charter of confirmation was granted by William Earl Marischal in 1623, and a new confirmation was given by Charles II. in 1661. It is a curious fact, that, neither in the charter of foundation, nor in any of the acts of parliament which relate to the college, is it recognised as a separate university. It nevertheless confers degrees in all the faculties, founding, as it seems unquestionably entitled to do, on the clause in the first act of confirmation, by which it acquired all the privileges belonging to any *college* within the realm.

Aberdeen.

Notwithstanding the precautions of the founder, innovations were soon made on the constitution of the college. A few years after its institution, another regent was appointed, additional members were admitted, and each professor, in conformity with the general practice, conducted his students through the whole course. In 1700 the privy council of Scotland assigned the Greek department to one professor; and in 1753 the system was finally altered by the senate. A professorship of mathematics was founded about 1613, and in 1616 a professorship of divinity. From this time the principal seems to have confined himself to the superintendence of the business and discipline of the college. The state of the college was the subject of frequent visitations appointed by the king, the privy council, and the parliament, by means of which, and by the interposition of the senate, a system of instruction differing but little from that which at present prevails was at a comparatively early period introduced.

Constitution.

Marischal College at present consists of a chancellor, rector, dean of faculty, principal, and thirteen professors. No division of the professors into faculties has ever been made. When degrees are conferred, promoters in the different faculties are appointed. The rector and his assessors, four in number, are elected annually by the students, according to the charter of foundation; but as it is the usual practice to elect a distinguished individual who is non-resident, the extensive powers which belong to the office have long been in abeyance. The dean of faculty is annually appointed by the senate and the minister of Aberdeen. The senate consists of the chancellor, rector, dean, principal, and professors. The first three are seldom present, and the affairs of the college are conducted by the ordinary members.

Revenue and Bursaries.

The Revenue of the college, including L.550. 6s. 8d. annually granted by the crown, amounted in 1836 to L.1638. 9s. 2d., to which must now be added the endowment of the chair of humanity, which is to be L.200. There are forty-five foundations for bursaries, for the benefit of 115 students. Their aggregate value is about L.1160 annually; and they vary from L.30 to L.5 and under. Sixty-seven of them are open to public competition ; the patronage of the others is vested in societies, and in private individuals. The two highest are awarded, by comparative trial, for excellence in mathematics, to students who have completed two sessions.

Session.

The Session in arts commences with a competition for bursaries on the last Monday of October, and ends on the first Friday of April. The session in the other faculties is somewhat shorter. Lectures in botany and conveyancing are given in summer. Toward the end of the session, the students in arts are examined in the public hall in presence of the principal and professors.

Discipline.

The professors have the power of correcting any impropriety of conduct in their respective classes, by the imposition of a fine, or by expulsion from the class ; but an appeal may be made to the senate, the rectorial court, and the chancellor. A public school, consisting of all members of the college, is assembled once a fortnight, for the purpose of investigating and correcting any breach of discipline. The bursars, as in King's College, must attend the curriculum in a particular order, and are examined at the commencement of each session before they are admitted to higher classes. The students who intend to graduate in arts are required to undergo an entrance-examination ; and before obtaining their degree, are examined on all the branches of the course, including the evidences of Christianity. For ten years preceding December 1840, candidates for the degree of doctor in medicine were required to take the preliminary degree of master of arts. By the present regulations this restriction has been removed, and an improved course of study prescribed.

The number of students in 1839-40 was 351; Graduates in arts, 21 ; in divinity, 0 ; in law, 2 ; in medicine, 2.

The fees for graduation in arts are, to alumni of the college, L.2. 14s. 8d. ; to those who are not alumni, L.8 ; in divinity and law, L.15 ; in medicine, for M. B. L.1, for M. D. L.11.

The following is a table of the professorships, with the date of their foundation, patronage, and the total emoluments of those which existed in 1836.

Office.	Founded.	Salary.			Patronage.
		L.	*s.*	*d.*	
Principal	1593	343	13	8	Crown.
Greek	1593	376	3	10	Crown.
Civil and natural history	1593	332	3	1	Crown.
Moral philosophy and logic	1593	328	1	11	Crown.
Natural philosophy	1593	335	7	1	Crown.
Mathematics	1613	335	2	8	Town Council.
Divinity	1616	112	8	4[1]	Town Council.
Medicine	1700	109	10	8	Crown.
Oriental languages	1723	97	18	6	Ramsay of Balmain.
Chemistry	1793	99	0	0	College.
Ecclesiastical history	1833	97	5	0	Crown.
Humanity	1839	200	0	0	Crown.
Anatomy	1839	...	...		Crown.
Surgery	1839	...	...		Crown.

The full fee for the first Greek, natural history, natural philosophy, and moral philosophy classes is L.3. 3s.; the average bursar's fees, L.1. 16s. 7½d. The full fees for the second Greek and mathematical classes are L.1. 1s. and L.2. 2s.; and the reduced fees, 10s. 6d. and L.1. 0s. 5¾d. For the class of medicine the fee is L.2. 2s., and for chemistry L.1. 11s. 6d. The bursars are entitled to attend the latter class *gratis*. The fees for the classes of anatomy and surgery are L.3. 3s. The professors of divinity and oriental languages receive no fees.

Lectureships in the following branches have been established in connection with the college: practical religion, evidences of Christianity, Scottish law and conveyancing, botany, materia medica, institutes of medicine, midwifery, medical jurisprudence, comparative anatomy, and agriculture. With the exception of the first, third, and last, the patronage is vested in the college.

UNIVERSITY OF EDINBURGH.

Foundation.

The university of Edinburgh owes its origin to James VI. In 1582 "the wise monarch" granted a charter, empowering the lord provost, magistrates, and council of the city to repair and build houses for the reception and habitation of professors and students of the liberal arts, humanity, philosophy, divinity, medicine, law, and any other liberal sciences (*quarumcunque aliarum liberalium scientiarum*). The same charter constitutes the municipal authorities, with the advice of the ministers (*cum avisamento ministrorum*), electors of all the professors, with the power of dismissing them should they find it necessary; and, with strange inconsistency, prohibits all persons not admitted by the patrons from professing or teaching any of the sciences within the liberties of the city. The king, who was ambitious of being commemorated as the founder and greatest benefactor of this literary establishment, inserted in the charter an imposing list of ecclesiastical properties for its support, which however were found to possess little more than a nominal value. Even the ground on which the college was built (the *Kirk of Field*) could only be obtained by purchase from a menial servant of the king, who had acquired a title to it; and, in like manner, the other royal benefactions proved in a great measure delusive.[2] The plan of the seminary was thus most extensive; and the patrons, being unfettered by the minute prescriptions contained in the foundation charters of the older universities, have had fewer difficulties to encounter in adapting it to the existing state of philosophy and science.

History.

The design of founding a college in the metropolis had been contemplated by the magistrates within two years after the reformation; but their endeavours were thwarted by the bishops, who were jealous of the reputation and prosperity of the seminaries placed under their immediate and official protection.[3] In 1562 the town supplicated from Queen Mary a gift of certain ecclesiastical property within the city, to be applied, among other things, for "collegis for leirning and upbringing of ye youth;" but received an evasive answer. Renewing their application the following year, they obtained a grant of "the Kirk-of-Field, to big ane schule;" but seem to have been prevented from carrying their design into effect. It was not till 1579 that successful measures were adopted. In this year the magistrates, encouraged by the ministers and other public-spirited individuals in the city, commenced building apartments for the accommodation of professors and students, and three years after obtained from the crown the charter of erection and confirmation. The chief promoter of the design was James Lawson, the successor of Knox as minister of Edinburgh, by whose recommendation Robert Rollock, one of the regents at St Andrews, and a man of high intellectual endowments, was selected in 1583 to fill the arduous situation of first and indeed sole regent in the new institution. The college was accordingly opened in October 1583, under the newly appointed regent; the number of students, who, as in the other universities, probably all belonged to the faculty of arts, was eighty-four. Rollock was engaged only for a year, with a promise of continuance and promotion if he conducted himself faithfully, and complied with the rules and injunctions of the patrons. His salary was to be L.40 Scots, or L.3. 6s. 8d., with a quarterly allowance of L.30 Scots for board, in addition to the fees to be paid by the students. According to the contract, he was to receive "for a year's education to the sons of burgesses, L.2 Scots, and to others at least L.3 Scots; a small sum, apparently, but not disproportionate to the scale on which the professor was maintained."[4] This rate of fees continued till 1595, when the town council ordained that the sons of gentlemen not burgesses of Edinburgh should pay L.8 Scots a year, and the sons of burgesses half that sum.

A second regent was appointed soon after the opening of the college; and in 1586, the town council, "having sufficient proif and experience of the lyfe and conversatioun" of Rollock, "and of his qualificatioun and learning," constituted him principal master, with all the emoluments of the appointment, committing to him all the authority vested in the principal of any college in the universities of the realm, and subjecting to his jurisdiction the regents established or to be established, with all other members of the college. He was required to attend to their doctrine and conversation, and to punish delinquents; but the council reserved to themselves the right of deposition, and of enacting statutes for the regulation of the seminary. A third regent was nominated in the same year, a fourth in 1589, and in 1597 a regent of humanity. Till 1620 the principal was regarded as professor of divinity, and his prelections were confined to that department. In this year a second professor of divinity was appointed; but several of the succeeding principals continued to read theological lectures. Those of Dr Leighton were published after his death.

The charter of erection was soon (1584) followed by another, in which the king, gratified by the success of the new seminary, conveyed to the magistrates and council certain property for its support. In 1612 another charter was granted by the king, ratifying those which had previously been given; and in 1621, an act of the Scottish parliament was passed, confirming various grants of property which had been made to the town of Edinburgh for the support of the institution. This act, as exhibiting the only rgh.

---

[1] To this sum must be added L.50 which the professor receives for delivering a weekly lecture to all the students on practical religion.

[2] Edinburgh Academical Annual for 1840, p. xiii. From the Introduction by Principal Lee we have obtained some interesting facts.

[4] Ed. Acad. An. p. xv.

nstitution which the college possesses, deserves particular tice. After detailing the establishment of the college, d the purposes for which it was instituted, the grants made carrying these into effect, the expense incurred by the city erecting the buildings, and various bequests made by well-posed persons for the support of the professors, the act de ares the anxious desire of the king for the increase of learn g within the borough, his willingness to confirm the former ants made to the college, and to extend to it all the im nities enjoyed by any other college within the realm, and ifies and approves the infeftments previously granted by majesty under his great seal, "togidder with the erection the said gryit ludging, manss, and hous of the Kirk-of- ild, in ane colledge for professioun of theologie, philo hie, and humanitie." The ratification concludes by de ring that the college shall "in all tyme to cum be callit ng James Colledge," and conferring on the magistrates as rons, and the rectors, regents, bursars, and students, "all erties, fredoms, immunities, and priviledges, appertening ane free colledge, and that in als ample forme and lairge ner as any colledge hes or bruikis within this his ma ie's realme." It is true that the term *university* is not ap ed to the seminary, either in this act or in the royal charter 1582; but the clause which has just been quoted confers on it all the powers and privileges of a university, and se necessarily involve the name.

From the first institution of the college, the town council, h the advice of the ministers and some eminent lawyers, ulated the mode of teaching, the discipline, the fees, and accommodation of the students. Students were admitted application to a magistrate, under whose authority they re enrolled; as in other universities, they were matricu ed by the rector or principal. It was the intention of the nders that all the students should lodge within the walls he college, and wear an academical dress. The annual t of a chamber to a stranger student, having a bed to self, was L.4 Scots; for which sum the town furnished ts, beds, tables, and shelves. Students whose parents e burgesses paid no rent, but furnished the rooms at ir own expense. The increase of numbers gradually put top to this practice. So lately, however, as the year 0, the English dissenters offered to contribute L.1000 ear, for the support of a *hospitium*, on condition that r students might participate in the benefit.[1]

he system of instruction originally pursued in the university not differ materially from that of the other Scottish universities. h of the four regents conducted his students, during the four s they remained under his care, over the entire curriculum of ature and philosophy, while the prelections of the principal e confined to theology. The following interesting account of course of study and early discipline is given by Principal Lee.[2] "uring the first year, about six months were spent chiefly in study of the Greek and Roman classics, accompanied by fre nt exercises in translation and original composition. The re nder of the session was occupied in the study of the Dialectics Ramus, without however discontinuing the reading of Greek Latin authors, and committing to memory and reciting large ions of the ancient poets and orators. In the second year, be s being exercised in Greek themes and versions, the students eeded in the study of logic, rhetoric, and some part of mathema The philosophical works of Aristotle were not neglected; and e later months of the session, the practice of oratory was en aged by public declamations. The third session, carrying for l the public studies and classical learning, introduced the youth e knowledge of some branches of natural history and philo y, and gave every one an opportunity of becoming acquainted the elements of the Hebrew tongue. In the fourth session, cs, physics, and metaphysics formed the principal object of y; but great part of the time was occupied in the practice of utation. The regent prescribed the subject, and every candi was matched with an antagonist, with whom it was necessary im to carry on a debate in presence of his teacher. The re s were required to exercise a habitual inspection of their charge, both in the public class and in the hours of recreation in the fields. The principal was bound to maintain a daily superintendence, presiding in the public devotions, and keeping a watchful eye over all the regents, students, and officers of the establishment, so that, when admonition or discipline was required, it might not be omitted or postponed till insubordination and irregularity became inveterate or scandalous. Every Lord's day was partly employed in the religious instruction of the students in their private classes, and chiefly in the public solemnities of divine worship." This course of study, which must have obtained the sanction of the patrons, goes far to justify the powers which had been vested in them by the charter of erection; and when carried into effect by the energy of the regents, readily accounts for the celebrity which the metropolitan university early acquired. The practice of each regent teaching the same class during the whole period of the course was discontinued in 1708, in consequence of a regulation by the parliamentary commission of visitation appointed in 1690. Since that time every professor has been limited to one particular department.

Edinburgh.

Peculiar constitution.

"The most striking circumstance," say the royal commissioners,[3] in the establishment of the university of Edinburgh, is, "that it is not erected into an independent seminary, but is subjected, in all essential points, to the provost, magistrates, and council of the city. To them is committed the superintendence of it, the appointment of the professors, and the privilege of removing them when so strong a step seemed expedient. The whole body is enjoined to obey the regulations emanating from the council; and even the powers of the principal are limited by the same authority. In fact, to the college, as a college, nothing seems to be given but immunities and privileges common to the other universities, and which do not seem to have any reference to its internal administration. No senatus academicus, or college meeting, with special authority to regulate the course of education, is recognised. Every thing specified is granted with a view to the magistrates and council; and in the only clause which may seem to imply that the college received a separate and independent jurisdiction, the mode in which it is introduced evinces that this could not have been the case." Accordingly, the council have always claimed and exercised the privileges which are conferred on them by the charter.

The number of professors, which in 1620 was seven, including the principal, was raised in 1708 to fifteen, one of whom was professor of Greek, the study of that language being required of all students of arts after the reformation. The present number is thirty-three. The right of instituting new professorships is vested in the patrons; and the promptitude which they have shown in adopting the best measures for the advancement of academical instruction is deserving of great credit. Some years ago the clergy of the city put forward their claim to a voice in the election of professors, on the ground that, in the original charter, the right of appointment was to be exercised *cum avisamento ministrorum*. The claim was for some time keenly agitated, and steps were taken to enforce it; but on application being made to the Court of Session in the case of a particular election, the court refused to grant an interdict, and the question was accordingly dropped. Eleven professorships have at various times been founded by the crown, of nine of which it has retained the patronage; but the exercise of this power is disputed by the council, as an infringement of their sole right of control, and a protest is regularly taken that it shall not hurt or prejudge their rights. In the case of some of the professorships, certain public bodies have been admitted to a share of the patronage, in consequence of contributing a part of the salaries of the professors. The professor of botany holds two commissions, one from the crown, and another from the town council.

The right of the patrons to interfere in regulating the course of study was of late years disputed by the principal and professors, and the subject was brought before the

---

[3] Report, pp. 99, 100.

Edinburgh.

Court of Session for adjudication. The court decided that the sole government of the university in all points, even in regulating the conditions of graduation, the course of study, and method of instruction, is vested in the town council. The council however has the discretion to leave matters of discipline and ordinary detail to the principal and professors; and the regulations which are from time to time made by them, are considered valid unless they are disallowed by the patrons.

For a considerable period the college was limited to the faculty of arts; the other faculties were successively recognised, as the course of instruction was extended. The medical school, which has of late years become so famous, had its origin so recently as the end of the seventeenth century, there being no professor of medicine previously to the year 1685. The school of law is still more modern. The class of public law was instituted in 1707, of civil law in 1710, of Scotish law generally, in 1722, and that of the theory and practice of conveyancing in 1825.

Want of Public Officers.

From what has already been stated, it will appear that the constitution of the university of Edinburgh differs essentially from that of other universities. Indeed it cannot be said to have any independent or well-defined constitution; the patrons being invested with the powers generally given to the universities themselves. No power is conferred upon it by the charter as an independent corporation, nor is any provision made for the appointment of public officers. There is no mention made of a chancellor; and although in early times the name was occasionally taken by the provost of the city, this must be regarded as an unauthorized assumption. For a long time there has been no chancellor of the university. The case in regard to the offices of rector and dean of faculty is nearly the same. "This important office," (the office of rector), say the commissioners,[1] "has been much less efficient in Edinburgh than in the other universities; and the existence of the office itself has been, apparently at least, suspended." It was held by several persons, though with frequent intervals, till 1640, when the council resolved to elect a rector annually, with six assessors, two members of council, two ministers, and two professors. But in the beginning of last century the office of rector was permanently annexed to that of lord provost, who, as head of the council, already possessed all the authority which could be deputed to the rector, and consequently the office, till within these few years, had become obsolete even in name. "It is, accordingly, explicitly asserted that no chancellor or vice-chancellor, rector or dean of faculty, exercises any authority or jurisdiction over the principal, professors, or students in the university of Edinburgh."[2] The business of the college is managed by a section of the town council, under the name of the college committee, who take charge of the revenue, communicate with the senate, and exercise a general superintendence over the seminary.

Principal.

The Principal occupies an anomalous position; he holds the same rank as the cognominal officers in the other universities, but apparently without any of the powers which the others exercise. Notwithstanding the stipulations made by the patrons to Rollock when he was promoted to the office, his authority seems to be extremely limited. The principal has long ceased to teach a class, and he has not for a considerable period taken an active part in superintending the instruction of any of the classes. He presides in the meetings of the senate, and is the official organ of the university in communicating with the crown, the patrons, and the public. Beyond this he does not appear, so far as we have been able to ascertain, to possess any real power or authority. The present principal reads lectures on biblical criticism, and has revived the ancient practice of delivering an annual address to the students.

Senate.

The Academical Senate is composed of the principal and professors, who, in right of their appointment, become constituent members. The principal presides, and has both a *deliberative* and a *casting* vote. The senate claims the right of instituting new faculties, and of fixing the privileges and immunities belonging to them. This court, however, is not mentioned in the charter, nor does it appear to have ever been recognised by the patrons, as possessing any independent powers. The meetings of the senate are called by the principal, or any member of the theological faculty.

Faculties.

The university contains the four Faculties of divinity, law, medicine, and arts, each of which has a dean, chosen by the faculty. The term Faculty was originally employed to denote the whole body of professors in their corporate capacity, but this application of it has long been supplanted by the designation of the senate. After the institution of a separate professorship of divinity, the two sets of professors were designated as the faculty of arts, and the faculty of divinity; but the precise time at which the distinct sections were recognised is nowhere recorded. It is to be borne in mind, however, that the four faculties merely perform certain duties under the senate, without whose sanction their proposals and regulations cannot be carried into effect. The faculty of arts comprehends the professors of languages and philosophy, with those of mathematics, rhetoric, practical astronomy, and universal history. The professor of natural history belongs to the faculty of medicine. The professors of agriculture and music have not yet been attached to any of the faculties.

The total Revenue of the university, derived from original property, from parliamentary enactments, from royal grants, and from the benefactions of individuals, amounted in 1825 to about L.3770. In this sum was included the income of the bursars, amounting to L.420. Of the remainder, the principal part was made up of the royal grants, which then amounted to L.1435, and were given as salaries to certain professors. A large portion of the college funds, amounting to L.13,119, having been under the management of the magistrates and town council, and being involved in the late embarrassment of the city's affairs, the act of settlement in 1838 provides an annual "sum of L.2500 for the maintenance and support of the college and schools of the said city, in full of all demands," &c.; and adds, that the said sum "shall be applied by the lord provost, magistrates, and council of the city, in defraying the obligations and payments incumbent upon them in relation to the debts due by the said city to the said college, in paying the salaries and house-rents due to or on account of the professors, in repairing and maintaining the college buildings, and in the other necessary expenses thereof, and the remainder towards the schools and educational purposes of the city;" in consideration of which payment, the "college debt" of L.13,119 is declared to be extinguished.

By the will of General Reid, dated 1806, a large bequest was made to the senate for endowing a professorship of music, adding to the library, and otherwise promoting the general interest of the university. This bequest, after being liferented by the testator's daughter, lately became available to the university. It amounted, after deduction of legacy-duty and expenses, to L.62,500. A professorship of music has since been established, and the series of annual concerts appointed by the will has been commenced.

The Bursaries attached to the university are thirty-four, the benefit of which is extended to eighty students: their aggregate value is L.1172 a year. Three are of the annual value of L.100; the others vary from L.30 to L.5 and under.

There are two Sessions. The winter session commences on the first Tuesday of November, and closes in the end of April. The summer session, during which a few classes of the medical faculty are taught, begins on the first Monday of May, and terminates at the end of July. The theological session is somewhat shorter. Each student pays a matriculation fee of L.1. No certain order for the attendance of classes, is prescribed by the statutes. Attendance on certain classes, however, is requisite for those who are destined to particular professions, or who aspire to academical degrees. It is recommended to students who mean to follow out a regular course of study in the faculty of arts, and it is enjoined on those preparing for the church, or proceeding to degrees, that they commence with the classes of languages and mathematics.

Candidates for the degree of Master of Arts must be in the fourth year of their academical studies, and must have attended the classes of humanity, Greek, mathematics, logic, rhetoric, moral and natural philosophy. They are required to give in their names to the dean of faculty on or before the last day of March. The examinations take place in April, and continue for three days, from twelve to four each day. The candidates are required to give written answers to questions, and translations of passages from classical authors put into their hands. Those who are found entitled to the degree are classified in the order of their proficiency, as ascertained by the results of the examinations; and the list of graduates so classified is affixed to the college gates, suspended in the library, and advertised in the newspapers. Students at the close of the third year of the regular curriculum of arts are admitted to that part of the examination which relates to classical proficiency; and those who avail themselves of this permission are examined in mathematics and philosophy at the close of the fourth year of their studies. The examinations are conducted by the professors of the faculty.

Arrangements have lately been made by the theological faculty for reviving the degree of B. D. Students who have finished rgh. eir theological curriculum, and who have previously taken the gree of A. M., are allowed to present themselves as candidates this new honour, and are required to undergo a strict examina- n on the evidences and doctrines of Christianity, in ecclesiastical story, and in oriental languages. Those by whom the examition is successfully undergone, receive from the faculty a cericate, which entitles them, on obtaining license, to apply to the iversity for the actual conferring of the degree. This we are lined to consider as a great improvement, and as likely to form owerful stimulus to students of divinity. It is to be presumed it the faculty intend this arrangement as preliminary to conferg on the bachelors the higher degree.

---

[1] Report, p. 114.

[2] Report, p. 115.

ne. The celebrity of Edinburgh as a school of medicine seems to mand of us a general statement of the course of study necessary obtain a Medical Degree. No student can be admitted to the aminations for the degree of doctor of medicine, who has not n engaged in medical study for four years, during at least six nths in each, either in the university of Edinburgh, or in some er university where the degree of M. D. is given, unless, in lition to three Anni Medici in a university, he has attended, ring at least six winter months, the medical or surgical practice a general hospital which accommodates at least eighty patients, l during the same period a course of practical anatomy, in which e three years of university study are admitted. Candidates st give sufficient evidence that they have studied, once at least, h of the following departments of medical science, under prosors of medicine, namely, anatomy, chemistry, materia medica, l pharmacy, institutes of medicine, practice of medicine, sury, midwifery and the diseases peculiar to women and children, eral pathology, and practical anatomy, during a course of six nths; clinical medicine, that is, the treatment of patients in a public hospital, under a professor of medicine, by whom lectures on the cases are given, during a course of six months, or during two courses of three months; and clinical surgery, medical jurisprudence, botany, natural history, including zoology, during a course of at least three months. They must attend the university of Edinburgh at least one year, must submit to the examiners a medical dissertation composed by themselves, and a written declaration that they are twenty-one years of age. Before candidates are examined in medicine, the faculty ascertain, by examination, that they possess a competent knowledge of the Latin language; and being satisfied on this point, they proceed to examine them, either *viva voce*, or in writing, on anatomy, chemistry, botany, institutes of medicine, natural history, materia medica, pathology, practice of medicine, surgery, midwifery, and medical jurisprudence. The examinations take place in May, June, and July, and the successful candidates are admitted to their degrees on the first lawful day of August. All degrees are conferred in the name of the senate. Honorary degrees alone are granted in the faculties of law and divinity. Edinburgh.

Discipline. The professors exercise no superintendence over the students, except within the walls of the college. Delinquents are brought before the senate, and admonished by the principal, or, if guilty of a grave breach of discipline, are expelled. The students wear no academical dress, nor are they required to attend any particular place of worship. Accommodation for 200 is provided in one of the churches in the immediate neighbourhood of the college.

The number of students in 1839–40 was 1298; graduates in arts, 4; in medicine, 111.

Fees for graduation in arts, L.3. 3s.; in medicine, L.25, including the stamp. The degrees in law and divinity being honorary, are always given without the payment of any fee.

le containing a List of the Professorships, the Date of their Foundation, the Patronage, the Salary attached to each, and the Fees exigible by the Professors.

General pathology	1831	None.			4	4	0	Crown.
Music	1839	300	0	0	...			Senate.
Biblical criticism[1]	1841	...			...			Crown.

To the office of principal is attached one of the deaneries of chapel royal, the emoluments of which are said to be under 00. A deanery has also been assigned as an endowment for recently instituted professorship of biblical criticism.

In the year 1590, the lords of session contributed one thoud pounds Scots, and the faculty of advocates and the society writers to the signet one thousand pounds, to be added to a sum advanced by the town council; and in consequence of the nation of this joint stock, it was stipulated that a professorship of humanity or laws should be founded, and that two delegates from the lords, two from the advocates and writers, and two from the town council, should elect the professor. This contract continues to be acted upon to the present time.—*Edin. Acad. Ann.* p. xviii.

3. The professor of botany holds two commissions, one from the crown as regius professor of botany and keeper of the garden, and another from the town council as professor of medicine and botany.

4. The six senior professors of the medical faculty have an addition to their emoluments, of about L.200 a year each, arising from the fees paid at graduation.

5. The four professorships set down as founded in 1708 are evidently the four regentships which, along with the principalship, formed the original establishment of the college, but the holders of which were not confined to the teaching of separate departments till the date here given.

6. The professors of the civil law, universal history, and Scotish law are elected by the town council, from a list of two names in each case, submitted by the faculty of advocates; a form which, in effect, gives the appointment to the latter body.

7. The class of clinical medicine is taught in rotation by certain of the medical professors, according to an arrangement among themselves. The fees are divided among the lecturers. The fee for the summer course is L.3. 3s.

UNIVERSITY OF DUBLIN.

Ireland is represented by her native historians as being, in the sixth, seventh, and eighth centuries, the university of Europe; and the manuscript remains of Irish literature belonging to that period, which are still preserved in various libraries, strongly corroborate the statement. During the three succeeding centuries, little is known of the state of learning; and the subjugation of the country by Henry II. in the twelfth century seems to have extinguished the feeble spark which still burned. Soon after the beginning of the fourteenth century, a university was established by a bull from John XXII., in connection with the cathedral church of St Patrick's, which continued for some time to support a feeble existence.

Trinity College.

The present university was founded in 1592, through the exertions of Archbishop Loftus, who prevailed on the corporation of Dublin to appropriate for its support the ground and buildings of the dissolved monastery of All-Hallows, on Hoggin Green, in the eastern suburbs of the city, at that time valued at L.20 per annum. A charter was soon after obtained from Queen Elizabeth, incorporating the university under the name of "The Provost, Fellows, and Scholars of the College of the Holy and Undivided Trinity, founded by Queen Elizabeth, near Dublin;" and empowering it to accept such lands and contributions for its maintenance as any of her charitable subjects should bestow, to the amount of L.400 a year. This was the extent of the royal bounty; no funds were provided for the erection of buildings, or for the support of the members of the college. The liberality of the Irish gentry was appealed to by circular letters from the lord-deputy, and a sufficient sum of money was by this means raised to enable the archbishop to commence the buildings. The first stone was laid on the 13th of March 1591, and the college was opened for the reception of students January 9, 1593. The whole income of the university, including voluntary and temporary contributions amounted in 1594 to the sum of L174. 18s., and in 1600 it was increased by certain allowances granted by the queen to L.544. 13s. 4d. Such was the foundation of the university of Dublin; and on this scanty provision it had to struggle for existence, often reduced, by the non-payment of rents, to the very brink of dissolution, till the beginning of the reign of James I., when it was endowed by that monarch with lands, which have since become valuable, in the province of Ulster, besides a pension of L.388. 15s. English, paid annually from the exchequer.

Original Constitution.

By the charter of foundation, the body corporate was to consist of a provost, three fellows, and three scholars, with power to increase their number as the funds of the college permitted. To the provost and fellows was intrusted the power of enacting statutes for themselves, and of appointing such acts and exercises as they might consider necessary to qualify for degrees. To them also belonged the duties of tuition, the scholarships being intended as foundations for the maintenance of the poorer students. The provost and fellows constituted the only university convocation or senate recognised by the charter, and with them resided exclusively the power of conferring degrees.[1] The fellows were to elect their provost on every vacancy of this office; and fellowships were tenable for seven years only after taking the degree of M. A. William Cecil Lord Burghley was nominated by the charter the first chancellor of the university, with a provision, that on all future occasions, the election of chancellor, vice-chancellor, and proctors, should belong to the provost and fellows.

In this, the original constitution of the university, many obvious defects soon began to show themselves. The election of a provost was a continual source of discord; and the authority of this officer being by the charter scarcely greater than that of the other fellows, was insufficient for the preservation of discipline in the college. The three fellows nominated by the charter were ecclesiastics, whose sacred duties prevented them from engaging in the actual labours of instruction; and accordingly, when the business of education really commenced, it was found necessary to obtain additional aid. The poverty of the society not admitting of their endowing permanent fellowships, an expedient was resorted to which afterwards led to an important alteration in the constitution of the college. About the year 1600, four *masters*, afterwards increased to seven, were appointed as lecturers of the junior classes, and, about 1610, were regularly constituted, by statute, probationer or junior fellows; from these the senior fellowships, instituted by charter, were filled up on every vacancy. About 1615, the number of senior fellows was fixed by statute at seven, and the number of probationer fellows at nine; the scholars, as at present, amounted to seventy. The junior fellows were to have no part in the government of the college, and were to be considered in every respect as *scholars*, except that they were recognised as college tutors, and employed in instructing others. This increase in the number of the fellows and scholars was most probably made soon after the income of the college was augmented by the grants of King James I. Though productive of beneficial effects to the college, by increasing the number of its instructors, it was at first the occasion of some very serious difficulties. The junior fellows claimed for themselves an express right by the charter to have a voice in the government and elections of the college; which was resisted by the governing body, on the ground that the title of *fellows* had been conferred on them, not as a matter of right, but by courtesy and *honoris causa*, and that their rights, as determined in the charter, were those of scholars only. Accordingly, Bishop Bedell's statutes, framed in 1627, provided against the difficulty, by dividing the scholars into nine *socii scholares*, or probationer fellows, and seventy *scholares discipuli*, or scholars, commonly so called, as being still *in statu pupillari*.

The dissensions to which we have already alluded continued to increase, and at last rendered the interference of the legislature absolutely necessary. Accordingly Archbishop Laud, who had been elected chancellor of the university in 1633, and had lately completed a revision of the statutes of Oxford, as chancellor of that university, undertook to remodel the statute-book which had hitherto been in use in the university of Dublin. The new charter and statutes, after encountering the most violent opposition, were read and published in the chapel of the university on Trinity Monday, June 5, 1637, and the oaths prescribed to the provost, fellows, and other officers, administered by the archbishops of Armagh and Dublin, the new visitors of the college. The opposition was not however quieted by the promulgation of the statutes. After Laud had fallen from his power, and was no longer able to protect his favourites, a vigorous prosecution was commenced in the Irish parliament against Bishop Chappel, the provost, by whose assistance the work of reformation had been carried into effect; but the rebellion of 1641, and the subversion of the British monarchy which so soon followed, diverted the attention of parliament to more important matters. The clamour appears to have subsided during the commonwealth, when the university became nearly extinct, and it was not revived after the restoration. The Laudian constitution, with some slight modifications, has continued till the present day; and to it the university owes much of its celebrity and usefulness.

---

[1] From this statute it is obvious that the university of Dublin is simply a *college* with university privileges and powers, and therefore differs in its constitution from the universities of Oxford and Cambridge, which are corporations distinct from the colleges or halls founded within their jurisdiction. In Dublin the provost and fellows are invested with the power of electing officers and conferring degrees, which, in the English universities, belongs to a body consisting of masters of arts and doctors in the higher faculties. At an early period forms were instituted for the public conferring of degrees by the vice-chancellor, in a solemn meeting of doctors and masters; and these, sanctioned by time, have long since become the established rule of the university.

The alterations made by the new charter in the constitution and government of the university were important, and had special reference to the dissensions which had been occasioned in the body by its former mode of government. The election of provost, and the power of enacting and repealing statutes, were taken from the fellows, and reserved to the crown. Fellowships, which had hitherto expired at the end of seven years after taking a master's degree, were made tenable for life. The nine probationer fellows were admitted members of the corporation, under the name of "junior fellows;" but the entire control, both as to discipline and finance, was vested in the provost and seven senior fellows, subject to the jurisdiction of visitors nominated by the crown, in whom the right of ultimate appeal was vested. In cases not provided for by the statutes, the provost and senior fellows were empowered to make new statutes not repugnant to those granted by the king, which new statutes were to be confirmed by the visitors, and to remain in force till the enacting body should think proper to rescind them. The election of officers, as chancellor, proctors, &c., was continued in the provost and fellows, the chancellor being permitted to nominate the vice-chancellor. The number of visitors was reduced from eight to two, viz. the chancellor, or, in his absence, the vice-chancellor, and the archbishop of Dublin. A special clause provided that no person should profess or teach the liberal arts in any other place in Ireland, without a special license from the crown. The changes since made in the statutes have consisted merely in the repeal of certain clauses which were found to be inconvenient; the augmentation of salaries, the foundation of professorships, and the regulation of the library; but no alteration has been made affecting the constitution of the college, except the foundation of additional junior fellowships by different sovereigns, whereby their number was increased from nine to eighteen. By a statute of Queen Victoria, dated on the 6th of May 1840, the statute of Charles enjoining celibacy on the fellows, has been repealed, and provision made for founding ten new fellowships. The addition to the fellowships, according to the new statute, is to "be made by the annual election, at the accustomed time and place, of one new fellow in this (1840) and in each of the next succeeding nine years, over and above the vacancies which may occur in the subsisting body." Of the ten additional fellows, only the four seniors for the time being are to be appointed tutors; but the remaining six are to enjoy all the other rights, profits, and emoluments, and perform other the duties and functions of junior fellows, and to be eligible to all other offices to which any junior fellows may now be elected or appointed." After the year 1849, when the number of additional fellows shall have been completed, though no vacancy should occur in the body of fellows, there is still to be an annual election of one, who shall succeed to the first vacancy, "unless there be at the same time two or more such persons so elected, in which case the senior of them shall succeed to the first vacancy." It is also ordained, "that after the year 1849, there shall be no more than two persons elected, whether as fellows or candidate fellows, in any one year, whatever number of vacancies may occur in the body."

Dublin.

James I., by his charter in 1613, granted to the provost, fellows, and scholars, the right of returning two representatives to the Irish parliament. The act of Union in 1800 restricted this number to one; but by the Irish reform bill, the original number was restored, and the right of election extended to all members of the university of twenty-one years of age, who at that time had, or who should thereafter obtain, a fellowship or scholarship, the degree of master of arts, or any higher degree.

Officers.

The entire government of the university is vested in the following Officers: the chancellor, who is elected by the provost and senior fellows, and whose office is tenable for life; the vice-chancellor, nominated for life by the chancellor, and who has the power to appoint a pro-vice-chancellor in special cases; the provost, appointed by the crown; the vice-provost, an annual officer, who is usually the first of the seven senior fellows; two proctors, chosen annually, one from the senior and the other from the junior fellows, for regulating the forms for taking degrees; two deans and a censor, whose duty it is to inspect the details of moral discipline; two librarians; a registrar, who performs the duty of secretary to the provost and senior fellows; a registrar for the electors admitted under the reform act; an auditor; six university preachers; four morning lecturers; and nine examiners.

Board.

The ordinary affairs of the college are managed by a Board, consisting of the provost and senior fellows, who hold a meeting every Saturday. The provost must be in holy orders, and a doctor, or at least a bachelor in divinity, and not less than thirty years of age. The fellows are all bound to enter into priests' orders, except three; one of whom is elected *Medicus* by the provost and senior fellows; the other two are elected *Jurista juris civilis*, and *Jurista juris Anglici*, respectively.

Senate.

The Senate of the university consists of all masters of arts, and doctors in the three faculties, who have their names upon the college books, and are resident in the university. The Caput *Senatus Academici* is a council consisting of the vice-chancellor, the provost, or in his absence the vice-provost, and the senior master *non-regent*,[1] resident in the college. The vice-chancellor and the provost are members of the caput *ex officio;* the senior master *non-regent* is annually elected by the vice-chancellor and provost, with the consent of the congregation. Every grace must pass the caput before it can be proposed to the senate of the university in public congregation, and each member of the caput has a *negative* voice.

Caput.

System of Instruction.

The System of Instruction is conducted by means of professorships, lectures, and periodical examinations. According to the statutes of Laud, all professorships were to be held by fellows. The provost was to appoint from the body of fellows, senior and junior, such a number as he thought fit, to be college tutors; and the fees paid by pupils, together with the emoluments of lectureships, professorships, and other offices, were to constitute the salaries of the fellows. At this period the only professorship in the university was that of divinity, which however was not recognised as the regius professorship till the year 1674. Two professorships, of jurisprudence and medicine, were appointed by statute, and the fellows who devoted themselves to these professions were exempted from the obligation of entering into holy orders. The increase of students, by augmenting the duties as well as the emoluments of the tutors, has now broken in upon the original spirit of the statutes; and the increased value of the college lands has supplied the means of assigning to the senior fellows ample salaries without subjecting them to the necessity of acting as tutors. Accordingly some annual offices, with several professorships, are now held exclusively by senior fellows, while the duties of tuition have been for many years confined to the junior fellows. By some recent regulations, four of the latter now hold offices incom-

---

[1] Each master of arts is called a regent during the three years following the time when he took that degree. The name had its origin in the duty formerly imposed on such masters, of regulating the disputations of the schools.

Dublin.

patible with that of tutor, and have consequently resigned their pupils; so that the number of tutors is limited to fourteen.[1] It was not till the latter end of last century that the principle was recognised of having professors in the university who were not fellows. In 1761 a statute was passed, which obliged the regius professor of divinity, on his appointment to that office, to resign his fellowship; and in the same year the regius professorship of feudal and English law was founded upon the same condition, if filled by a fellow. In 1774 Provost Andrews bequeathed to the college an endowment for a professor of astronomy. A school of medicine was established by act of parliament in 1785, consisting of three professorships not tenable with fellowships; and besides these, two professorships of modern languages were founded in 1777. These, with the exception of the professorship of political economy, moral philosophy, and biblical Greek, are the only professorships which can be held by persons who are not fellows.

The following is a table of the professorships and lecturerships, with the date of foundation, and the patronage.

Office.	Founded.	Patrons.
Regius professorship of divinity	1607	Provost and senior fellows.
— — of civil and canon law	1668	
— — of feudal and English law	1761	Provost and senior fellows.
— — of physic	1637	
— — of Greek	1761	
King's lectureship in divinity	1729	
Lord Donegall's lectureship in mathematics	1674	Provost and senior fellows.
Royal astronomer of Ireland	1783	Provost and senior fellows.
Smith's professorship of natural philosophy	1724	Two candidates are selected by the provost and senior fellows, the one of whom is appointed by the board of Erasmus Smith, for such time as they think proper; Smith's exhibitioners being, *cœteris paribus*, preferred.
— — of oratory	1724	
— — of mathematics	1762	
— — of history	1762	
— — of oriental languages	1762	
Professorship of anatomy and surgery	1785	Provost and senior fellows.
— of chemistry	1783	
— of botany	1785	
Lectureship in natural history	1816	Provost and senior fellows.
Professorship of French and German	1777	Crown.
— of Italian and Spanish	1777	Crown.
Whately's professorship of political economy	1832	Provost and senior fellows.
Professorship of moral philosophy	1837	
— of biblical Greek	1838	

The professorial system, as established in the university, has never been efficient. Some of the professorships and lectureships are annual offices, and these, with others which are not annual, are all held by persons whose time is occupied by other duties; and besides this, the lectures of the professors are not sufficiently connected with the education of such as are looking for university honours or degrees. The education of the students in arts is intrusted almost exclusively to those of the junior fellows who exercise the functions of tutors.

Terms. The academical year is divided into three terms, Michaelmas, Hilary, and Trinity. Those of Michaelmas and Hilary are followed each by a short recess; that of Trinity by a vacation of three months. Terms are kept, during the under-graduate course, not by residence, as at Oxford and Cambridge, but by answering at the examinations held for the purpose at the beginning of each term. Students of divinity, law, and medicine are required to attend the lectures of the professors, and therefore reside either in the college or in the city. The under-graduate course consists of four years, in each of which the students are distinguished by the titles of junior and senior *Freshmen*, and junior and senior *Sophisters*. After taking his first degree, the student becomes successively a junior, middle, and senior *Bachelor*, when he is admitted to the degree of master of arts. A bachelor of divinity must be M. A. of seven years' standing; a doctor in divinity must be B. D. of five, or a master of arts of twelve: a bachelor of laws must be of six years' standing.[2] A doctor of laws must be LL. B. of four years' standing, or a master of arts of six. A bachelor in medicine must be B. A. of three years' standing, or M. A. of two; a doctor in medicine must be M. B. of five years', or a master of arts of seven years' standing. A bachelor in music must compose and perform a solemn piece of music before the university; a doctor in music must be Mus. B. of five years, and perform a similar exercise. The fees for B. A. are L.7. 17s. 6d., for M. A. L.9. 19s. 6d., for B. D. L.13. 15s., for D. D. L.26, for LL. B. L.11. 15s., for LL. D. L.22, for M. B. L.11. 15s., and M. D. L.22.

Ranks. The students are arranged in four Ranks: 1. Noblemen and baronets, styled nobiles, filii nobilium, and equites, who are entitled to the degree of B. A. *per specialem gratiam*. 2. Fellow commoners, who are entitled to graduate at the commencement of their fourth or senior sophister year. These two classes pay a high annual stipend, and dine at the same table with the fellows in the commons hall. 3. Pensioners, who constitute the great body of the students. 4. Sizars, who have their commons free, and are exempted from annual fees. The number of sizars is limited to thirty-six, and admission is obtained after a very strict examination held annually to supply vacancies, the endowment being tenable for four years. Each of these classes is distinguished by a particular dress. The mode of admission is by an examination, held at the beginning of each term, in the public theatre of the college. The examiners for entrance are the junior fellows. The senior lecturer commences the examination by proposing to the candidates a subject, on which they are required to write in Latin, or else by giving them a few sentences in English to translate into that language. After a sufficient time allowed for this exercise, the examination in classics begins. The following is the course appointed.

Greek.—Homer, Iliad, lib. i.–viii.; Walker's Lucian; Nov. Test. the Gospels and Acts; Xenophon's Anab. lib. i.–iii.

Latin.—Sallust; Horace; Virgil, Æn. lib. i.–vi.; Terence, Andria, and Heautontimorumenos; Juvenal, Sat. iii. x. xiii. xiv.

The examination is conducted *viva voce;* each examiner takes a separate book, and goes round the hall, requiring from the candidates separately an oral translation of a few lines or sentences. and asking some grammatical or historical questions. After the examination, *placcs* are determined by the reports of the examiners. Entrances are also held on the first Monday of every month during terms. Those who enter after November, and propose to go on with the junior freshman class, must pay a year in advance, instead of half a year, and their names must be on the college books at latest before the eighth of July. The examination for sizarships is held annually on the first Tuesday and Wednesday after Trinity Sunday; and the candidates, together with the ordinary entrance course, are examined in all the additional classics read in the first two terms of the junior freshman year.

The following is a table of the half-yearly charges, including tuition, but exclusive of rooms and commons.

	Entrance, including the first Half Year.	
Noblemen	L.60 0 0	L.30 0 0
Fellow-commoners	30 0 0	15 0 0
Pensioner	15 0 0	7 0 0
Sizar	5 0 0	... ...

Every student at his admission must select one of the fourteen junior fellows who act as tutors to be his instructor, and the guard of his interests during his academic life. The tutors duri term deliver lectures to the first three classes, each to his own p ils. The subjects of these lectures are the science, and somet es also the Latin book, appointed by the college for the examin ion of the ensuing term; and they are conducted in the same w as in the English universities. Besides the lectures of the p ate tutors, all under-graduates who reside in the college or in t city are bound to attend the lectures on science and Greek d vered by the college lecturers. Freshmen are also required to a nd weekly catechetical lectures. Three distinct Courses are a ointed, one in mathematics and physics, another in logic and n ral philosophy, and a third in classics, in any one or more of w ch a student, according to his taste and inclination, may cont d for honours at his degree examination. In each course two r ks of honour-men are formed, called senior and junior Moderat , the number in each rank being limited to one fortieth of the e ire class.[1] The science taught in the first year of the course is athematics; in the second, logic; in the third, astronomy and p sics; in the fourth, ethics; in addition to which the student n st be prepared to answer in a certain portion of Latin and G ek, selected from the classical writers. An extended course of st lies is prescribed for those who aspire to academic honours. A the examinations, senior and junior freshmen are accountable f the science taught in all the preceding terms from the beginn g of the course; senior and junior sophisters, for the science t ght from the beginning of the third or junior sophister year; b except for honours at the degree examination, the science of t freshmen classes is not carried beyond the second year. To k his class, a pensioner must have credit for two out of the three e minations of that class, one of which must be the third or ober examination, if he is either a senior freshmen or a senior s hister. A senior sophister who may not have secured credit f his October examination, may qualify himself for his degree b nswering in the same business at any subsequent examination o enior sophisters; and a senior freshman may repair the like o ssion in the same way at the first examination of the senior s hister year. Fellow-commoners and sizars are subject to the s e rule, with some slight exceptions.

---

[1] This was the number previous to the statute of Victoria. When the additional fellows provided for by this statute are elected, the number of tutors will be increased to eighteen.

[2] A bachelor of arts may take this degree in three years, and a master of arts in two.

ach term commences with an Examination, not only of the s lies of that immediately preceding, but, with the exceptions a ady stated, of the substance of most of those which had been p viously gone over. These examinations are of peculiar imp tance in the university of Dublin, from their effect upon the s lents generally, and because they constitute, to a very large p portion of those who graduate there, the only university educat they receive. We have already alluded to that peculiarity o iscipline by which residence is not enforced on under-graduates. A student, unless he be a scholar, is permitted, at his own disc ion, to prepare himself for the examinations without residing i he college or in the city; and on his being represented by his t or as a resident in the country, no other academic duties are r uired of him. The expense of residence would be an insupera obstacle to many who are at present in the university; and t efore, by the admission of non-resident students, some part o he advantages of a university education are extended to a large n ber of individuals by whom, if residence were enforced, not even t part would be attainable. Thus, while five or six hund l students annually receive at Dublin all the advantages that r dence and college discipline can communicate, about an equal n ber are induced to study, and are furnished with the means of a ining one at least of the objects proposed by a university educ on, namely, the power of acquiring knowledge. The examiners a the fellows, masters of arts, or doctors, resident in the coll , who are selected by the provost and senior fellows. The s lents of the same class or year assemble together for examin on, and are separated into *divisions* not exceeding forty, to e of which three examiners are assigned, one in science, one i Latin, and one in Greek. The examination of each class occ ies four days; the first two days being devoted to the detern ation of *judgments*,[2] and the remaining two to the separate e mination of honour-men. The examiners of the first two d s select from their divisions such as they deem qualified to b ome candidates for honours or prizes, and return their names to the senior lecturer. The examination of those who have not been selected for honours is then concluded; but on the third day the candidates selected for honours in science are examined by a separate court of examiners; and on the fourth day, the candidates for honours in classics; the examination, as in the former case, being conducted partly *viva voce*, and partly by written papers. The prizes, during the first three years, are books of the value of L.4 and L.2, given at the close of the year to the best answerers during the three examinations. The number of prizes is subject to the same limitation as the honours. At the Michaelmas examination of the fourth year, the examiners of the first two days select from among the candidates for degrees those whom they deem qualified to become candidates for honours in any of the three departments of the academical course. Those belonging to the same department are then examined together by a body of examiners during two days, by whom they are arranged in two divisions of senior and junior moderators. The limit to the number of moderators of each division is determined, as in the case of honours and prizes, at the previous examinations. At the conclusion of each examination, lists of the successful candidates for prizes, honours, or moderatorships, are made out by the senior lecturer, who is required to insert them in his book, and also to have them affixed to the college gates, and published in the newspapers. The successful candidates of each rank are arranged according to the order of their standing on the college books, excepting only the senior moderators, who, at the degree examination, are placed according to the order of merit.

Dublin.

Comitia.

The Comitia, or commencements, for conferring degrees, are held twice a year; on Shrove Tuesday and the Tuesday next before the eighth of July. The grace of the house for a degree in any faculty must first be granted by the provost and senior fellows before it can be proposed to the caput. Those who have been admitted to a degree at the board are then *presented* to the vice-chancellor and the whole university, at a public congregation, by the regius professor of the faculty in which the degree is to be taken; or if it be a degree in arts, by one of the proctors. If no member of the caput objects, the presenting officer *supplicates* the congregation for their public grace, and collects their suffrages; if the *placets* be the majority, the candidates kneel before the vice-chancellor, who confers the degree, according to a formula fixed by the university statutes.

Scholarships.

The examination for Scholarships is held annually on the Thursday and Friday before Whitsunday. The examiners are the provost and senior fellows. Scholarships are open to all students, being Protestants, who have reached their third under-graduate year, and are tenable till the holder is entitled to the degree of master of arts. Students of higher standing are also permitted to become candidates, but an extended course of reading is required of them. The course appointed includes all the classics read for entrance and in the extended course for under-graduates, to the end of the second examination of the junior sophister year; or, should the candidate be of higher standing than that of junior sophister (reckoned from the time of his entrance), to the end of the last examination which he might have answered had he proceeded regularly with his class. The examination is conducted entirely *viva voce*. The scholars have their commons free of expense, and their rooms for half the charge paid by pensioners; they pay for tuition, but are exempted from college charges or *decrements*, and receive from the college an annual salary.

Fellowships.

The Fellowship examination, when a vacancy occurs, is held by the provost and senior fellows, on the Wednesday, Thursday, Friday, and Saturday preceding Trinity Sunday. Two hours are devoted to each subject, and two subjects occupy a day. The examination continues from eight to ten A. M. and from two to four P. M. each day. The following is the order in which the subjects are taken.

	Morning.	Afternoon.
First day........	Logic....................................	Mathematics.
Second day......	Physics................................	Ethics.
Third day.......	History and chronology............	Greek, Latin, and Hebrew.
Fourth day......	Latin verse composition............	Latin prose.

The terms first class, second class, &c., in Dublin, mean students who are in their first, second, &c. year.

The examiners are required to fix the merit of every candidate in each subject appointed for the examination, according to a scale of six grees, technically called *judgments*, which has been long in use for this purpose. The highest degree of merit is marked by the judgment *ime*, which however is very rarely given, and is therefore regarded as a very high honour. The remaining degrees are *valde bene*, *bene*, *satis e*, *mediocriter bene*, and *vix mediocriter bene*. The student who receives this last judgment loses his examination, or, in technical language, is *tioned*; that is to say, the examination in which he is thus disgraced is not suffered to count in the number required for keeping his year, or his degree. If he have received two or more such judgments, besides losing his examination, he is *turned down* to the bottom of his class; if cautioned again, on the succeeding examination, he is put down into a lower class. The classical examiner gives three judgments, one Greek, another for Latin, and another for a theme. The number of judgments given by the science examiner varies from one to four, acding to the subjects read by the class.

"In each of these subjects a course sufficiently extensive is prescribed by the examiners. The examination is conducted altogether *viva voce*, and in the Latin language. Even the classical examination of the third day is conducted in the same manner; a Greek or Latin classic is placed in the hands of each candidate, and he is required to translate or paraphrase a few lines of it orally in Latin. The income of a senior fellow, arising from various sources, is generally estimated at about a thousand pounds per annum; but it necessarily fluctuates according to the offices held, and, on an average, is probably not so great. The emoluments of fourteen of the junior fellows are derived entirely from tuition."

The college has at its disposal twenty-one lucrative benefices in the northern dioceses, and the vacancies are supplied by the fellows. By the late act for regulating the established church in Ireland, the archbishops of Armagh and Dublin were required to select a benefice, not exceeding the annual value of L.1000, out of each of the ten extinguished bishoprics, to which benefices, when vacant, they are to nominate a fellow or ex-fellow of the college. The incomes of the senior fellows arise partly from the stipends of the professorships which they hold, and partly from the college lands. The provost derives his income from lands appropriated to his use.

The number of students matriculated in 1839 was 38 fellow commoners, and 340 pensioners. Students on the books, December 1840, 1100.

CONTINENTAL UNIVERSITIES.

The following is a list of the existing European universities, exclusive of those of Great Britain, Ireland, and France. The number of students for the years previous to 1840 has been taken chiefly from the "Genealogisch-historisch-statistischer Almanach für das Jahr 1840," published at Weimar. When the year is not mentioned, the number of students given may be taken as the average attendance.

[1] The university of Wittemberg was united with it in 1815.

[2] Transferred from Abo after the fire in 1827.

[3] Founded by the removal thither of the former university of Landshut.

ROYAL UNIVERSITY OF FRANCE.

France.

rance, before the revolution, contained twenty-three ur ersities, of which the most important have already been de ribed. The others were those of Aix, Angers, Avignon, Be ançon, Bourges, Bordeaux, Caen, Cahors, Dijon, Douai, N tes, Orange, Pau, Perpignan, Poitiers, Pont-à-Mousso Reims, Strasburg, and Valence. These venerable ins tutions disappeared during the revolution, and the public ducation of the country was for some time left without an legislative protection. After several unsuccessful atte pts to establish a national system, an Imperial Universit was instituted in 1808, which, with some modifications, ha survived the various changes of government which the co try has since undergone. The *Royal University of F nce* embraces the whole system of national education, an includes all the institutions for imparting instruction wh h are spread over the whole kingdom, from the lowest sc ols up to the royal colleges. The term may thus be co idered as synonymous with the French national syste of education. The university is placed under the dire on of a council of six members, called the "royal co cil of public instruction," of which the minister of public nstruction is the official president. Each counsellor has th pecial charge of one or more divisions of public instr tion. Subordinate to this council are the inspectors-gene l of the university, who are required to examine once a ye the institutions of every description, each within a certai district assigned to him, and to transmit a report to the co cil. The university is composed of twenty-six *acade es*, each of which comprehends two, three, or more of th departments into which the kingdom is divided, and co ains one or more royal colleges. The presiding officer of ch academy is the rector, who is appointed by the minist of public instruction, and is assisted by two inspectors and a uncil. The governing body of each academy has the su rintendence of all the communal colleges, institutions, *pe ions* (boarding schools), normal schools, or schools for the ed ation of teachers, and primary schools, within the distri which the seminary comprehends. Besides the supe ntending body, the academy includes the teaching co s, or faculties; namely, the faculties of letters, science, m icine, law, and theology, all of which however do not ac ally exist in every academy; in some, indeed, there is no or nization of faculties. The faculties consist of a variable nu ber of professors, one of whom is dean, and a comm ee of whom examine candidates for degrees. There ar however some institutions which are not subject to the ju diction of the university; as the College of France, the M eum of Natural History, the *Ecole des Chartes*, School of riental Languages, the French Institute, and societies of l kinds for the advancement of knowledge.

ie royal colleges are supported chiefly by the government, and th salaries of the professors, which are generally from L.80 to L. 0, are paid from the budget of the minister of public instructi The students are divided into two classes, the *internes* and ca *nes*, or boarders and day-scholars. The communal colleges ar upported principally by the communes in which they are situ e; some of them have endowments, but the majority depend ch ly for their support on the fees paid by the students. The pr essors or teachers receive but small salaries, varying from L.40 to .120. In 1833 a law was passed, ordaining that every comm e by itself, or by uniting with others, should have one school of lementary instruction; that every commune the population of hich exceeded 6000, should also have a school for superior inst ction; and that every department should have a normal school, ei er by itself, or in conjunction with some other department. In th chools of elementary instruction, reading, writing, arithmetic, an the established system of weights and measures, are taught; an the schools for superior instruction, in addition to the acq ements of the lower schools, embrace the elements of geom ry, and its application to the arts; the elements of chemistry an natural history, as applied to the ordinary habits and pursuits of fe; the elements of history and geography, and more especially the history and geography of France. Since the passing of this law, the cause of education has advanced rapidly; the number of schools has greatly increased, and the proportion of children at school, though less than in some of the neighbouring countries, is about one third greater than before 1833. The following is a tabular view of the institutions comprised in the University of France in 1836.

Academies.	Departments.	Royal Colleges.	Professors.	Internal Students.	External Students.	Communal Colleges.	Institutions.	Boarding Schools.	Normal Schools.	Primary Schools.

There are six faculties of *Catholic theology*, at Aix, Bordeaux, Lyon, Paris, Rouen, and Toulouse; and two of *Protestant theology*, one, of the Lutheran or Augsburg Confession, at Strasburg, and another, of the Calvinist or Helvetic Confession, at Montauban, under the academy of Toulouse. The faculties of law are nine, at Aix, Caen, Dijon, Grenoble, Paris, Poitiers, Rennes, Strasburg, and Toulouse. There are three faculties of medicine, at Grenoble, Paris, and Montpellier; with seventeen secondary schools of medicine. The faculties of science are nine in number, at Paris, Bordeaux, Strasburg, Caen, Toulouse, Montpellier, Dijon, Lyon, and Grenoble; those of letters or literature, seven, at Paris, Strasburg, Bordeaux, Toulouse, Caen, Dijon, and Besançon. In order to become a student in the faculty of law or theology, a person must have taken the degree of bachelor of letters; and a course of three years in either faculty is requisite to obtain the degree of bachelor; for the degree of doctor, four years; and to obtain the degree of doctor in divinity, the candidate must defend a final and general thesis. Candidates for the degree of doctor in medicine must have taken the degree of bachelor of letters, and also of sciences, and must complete a course of four years. The faculties of law and medicine at Paris are greatly distinguished. The former has sixteen professors, and had in 1836 upwards of 3000 students; the latter twenty-seven professors, and, in 1836, about 4000 students.

At the end of 1837, the total number of schools, public and private, throughout France, was 53,920; 39,504 for boys, and 14,416 for girls. The number of pupils at the same period was 2,651,492; 1,552,847 boys, and 1,098,645 girls. The masters of the elementary schools have a residence, and receive a yearly salary of 200 francs, or little more than L.8; the masters of the superior schools have a residence and a salary of 400 francs, or somewhat more than L.16. The whole charge to the state of the department of public instruction, according to the budget of 1838, was 19,005,673 francs, or nearly L.800,000, which was distributed as follows:—

	Francs.
Central administration	686,623
General services	238,000
Departmental and academic administration	919,900
Superior instruction—faculties	1,972,050
Secondary instruction	1,655,600
Elementary instruction, general fund	1,600,000
— — additional	3,500,000
Primary normal school	200,000
Literary and scientific establishments	7,676,500
Subscriptions to literary works, &c	557,000
Total	19,005,673

United States.

COLLEGES IN THE UNITED STATES.

To render our account of the seminaries for higher education as complete as possible, we have added, from the "American Almanac for 1841," a list of the colleges in the United States, which are sometimes dignified with the name of *Universities;* but it must be borne in mind that a large proportion of these furnish instruction only to a limited extent; and none of them, we believe, will bear a comparison with the great majority of the European seminaries. We have subjoined, from the same source, lists of the medical, theological, and law schools.

COLLEGES.

No.	Name.	Place.	Founded.	Instructors.	Students.

Remarks.

The colleges marked thus (*) are under the direction of the *Baptists;* thus (†), *Episcopalians;* thus (‡), *Methodists;* thus (§), *Catholics.*

With respect to the colleges which are *unmarked*, the prevailing religious influence of those in the New England states, is *Congregationalism;* of the most of the others, *Presbyterianism.* Norwich university, Vermont, is an institution recently established by the *Universalists.*

By *students* in the above table, with an exception of a few of the colleges in the southern and western states, is meant *under-graduates*, or members of the four collegiate classes, not including such as are pursuing professional education, or such as are members of a preparatory department.

The whole number of students on the catalogue, including those of theology, law, and medicine, as well as under-graduates, in Harvard University, in 1839, was 426; in Yale College, 608, In the university of Pennsylvania, in 1838-9, in the collegiate department 113, in the academical department 128, and in the medical department 402,—total, 643.

Some of the colleges above enumerated are not in full operation, and scarcely deserve a place in the table. Several other colleges have been incorporated, which are not yet fully organized.

The information given in these tables has been obtained from various sources. Much aid has been derived from a valuable document entitled *Statistics of Colleges and Theological Seminaries in the United States*, found in the Appendix to the "Twenty-fourth Annual Report of the Directors of the American Education Society."

LAW-SCHOOLS.

Place.	Name.	Prot.	Sudents.
Cambridge, Massachusetts,	Harvard University,	2	120
New Haven, Connecticut,	Yale College,	2	45
New York City,	Law Dep. New York Univ.	3	..
Carlisle, Pennsylvania,	Dickinson College,	1	23
Williamsburg, Virginia,	William and Mary College.	1	36
Charlottesville, Virginia,	University of Virginia,	1	72
Lexington, Kentucky,	Transylvania University,	3	71
Cincinnati, Ohio,	Cincinnati College,	3	25

Schools for the study of law are much less frequented than schools for the study of the other professions. The first institution of this nature, of much note, that was established in the United States, was the law-school at Litchfield, in Connecticut, which had, from 1798 to 1827, 730 students; but it is now discontinued.

PART II.—SCHOOLS.

he length to which the first part of this article has exte ed leaves us room merely to mention what was intended o form the subject of the second. In thus extending th first part, to the exclusion of the second, we have been in enced by a wish to furnish accurate and satisfactory info ation on a subject which is important and interesting, wl e to the general reader it is by no means easily accessil . The subject of schools does not yield to the other, eit r in importance or interest; but it is one of which someth g is more generally known, and on which extended info ation can be more readily obtained.

e duty of providing schools for the education of the people ha been generally acknowledged and acted upon by the governme s of modern Europe; and accordingly we find established in th arious countries a national system of instruction more or less ex nsive, according to the circumstances and capabilities of each. T his rule, which is all but universal, England forms a remarkab exception. Here no system of public instruction has been est lished by the authority of the legislature; and the education of e people has been left to individual beneficence, and to the ex ions of public societies. Nearly all the grammar-schools in th ingdom owe their origin to the former source; and there is pe ps no country in which so large an amount of property has be appropriated for the education of youth. The estates and oth property left for educational purposes would, it is believed, if perly managed, yield an annual revenue of L.400,000. The am nt actually realized falls far short of this, and its utility is fur er impaired by the conditions and restrictions under which it is plied. The grammar and endowed schools, which are nume us, were principally intended for the upper and middle classes; an some of them, as Eton, Westminster, and Winchester, are no attended solely by the sons of the nobility and higher gentry It was not till a comparatively recent period that any vigorous eff was made to supply the lower classes with education, or to bri this powerful instrument of civilisation within the reach of th hildren of the poor. Much however has been done during th resent century, and many schools have been founded for this lau ble purpose. These consist chiefly of what are called Su ay Schools, National Schools, and British and Foreign Sc ols. The *Sunday Schools* owe their origin to the benevolent eff s of Mr Robert Raikes, a printer of Gloucester, by whom th were established in that town in 1781. Being patronized by ma pious and philanthropic individuals, the plan extended rap ly, and has been productive of incalculable benefit to the po The meetings are held in the afternoon of Sunday; and th upils consist of adults as well as children. Though inte d chiefly for the communication of religious instruction, in ma of these schools reading and writing are also taught. Acco ng to the official returns, there were in England and Wales, in 33, no fewer than 16,828 Sunday schools, attended by 1, ,890 children and adults. Of these, 6247 schools, attended by 50,107 children and adults, belonged to dissenters. The N *onal Schools* are under the control of the "National Society for promoting the Education of the Poor," established in 1811, and are conducted on the system recommended by the late Dr Bell of Madras. This society is supported solely by members of the established church, and the church catechism is used in its schools. According to the report for 1839, the schools and scholars were,—4291 *places*, with 4382 Sunday and daily, and 2197 Sunday schools, containing 180,767 boys and 146,752 girls as Sunday and daily scholars, and 122,084 boys and 130,928 girls as Sunday scholars only; making, with the Infant Schools, in all 6778 schools, with 597,911 scholars. The *Schools of the British and Foreign School Society* are not connected with any religious sect, but are open to all pupils, of whatever creed. This society maintains a considerable number of schools in all parts of the country, and has contributed extensively towards the diffusion of elementary education among the working classes. The system adopted is that of Joseph Lancaster, through whose exertions the society was formed in 1810. According to the education returns in 1833, the number receiving instruction in daily schools was 1,276,947. At an average of England and Wales, perhaps from one-tenth to one-eleventh part of the population may be attending schools and seminaries of various kinds. We believe however that, speaking generally, the education communicated is of an inferior description, and that, in point of quality, it is decidedly below the standard of Holland, Prussia, Scotland, and some other countries.

In Scotland, in addition to the schools on the parochial system, of which a short account will be found in the article SCOTLAND, much has of late years been done for the more general diffusion of education among the great mass of the people. The "Society for propagating Christian Knowledge" maintains 159 schools in different parts of the kingdom, which are attended by 12,619 scholars; and the "Committee of the General Assembly," whose exertions are directed chiefly to the Highlands and Islands, have under their care 126 schools, which are attended by 12,000 scholars. Nor have the various dissenting bodies been backward in contributing towards the same benevolent object. The schools supported by them in the large towns amount to a considerable number. The state of primary education in Scotland will be best exhibited by the following abstract from the Parliamentary Report (Session 1837), prepared from returns by the parochial clergy.

Totals, . . .	1047	1170	3995	4469

It appears that, taking the largest amount of attendance, a ninth of the whole population of Scotland is, on an average, receiving education in public schools, either parochial or non-parochial. This is exclusive of private boarding schools, both for males and females, and of those who are educated under domestic tutors.

The schools under the superintendence of the "Board of Education" in Ireland, of the origin of which an account will be found in the article IRELAND, continue to extend over every part of the island, notwithstanding the violent opposition which the system has had to encounter. The number of schools in December 1839 was 1581, which were attended by about 205,000 scholars. In August 1840, 200 schools had been added to this number; and at that date there were before the board 309 applications for aid, about 200 of which were from presbyterians. (B. W.)

Unterwalden || Uppingham.

UNST. See Zetland.

UNTERWALDEN, one of the cantons of Switzerland, and one of the most ancient of the confederacy, having been established as an independent state in the year 1308. It is bounded on the north by Lucerne and the lake Lucerne, on the east by Uri, on the south by Berne, and on the west by Lucerne. The extent of it is 198 geographical square miles. It is divided into two parts, called *Obwalden* and *Nidwalden*, or the upper and lower forest. The capital of the former is Sarnen, with 2000 inhabitants. The capital of the latter is Stanz, with a population of 2000. These two divisions form separate states, having similar democratic constitutions, but distinct administrations; and they alternately send deputies to the general assembly of the confederation.

The inhabitants of both are of German origin, and speak a patois of that language. They are a simple pastoral people, attached to their ancient customs, and bigoted to their faith, which is that of the Romish church, under the episcopal jurisdiction of the bishop of Constance. There are thirteen parish churches, and five churches in the same number of monasteries. In 1838 the population amounted to 22,571.

The sovereignty is in the whole of the males above twenty years of age, who assemble on the last Sunday in April, when the government is appointed, and the laws which are proposed by the executive power are agreed to or rejected. Each man is taught the use of arms, and is enrolled as a soldier in the militia. The tax paid to the general confederacy is 1910 francs, and the contingent of men is 383. The chief, called the landammann, is chosen yearly; and the members of the council also resign their offices each year, but are almost always re-chosen. This description of the government applies to both the states which form the canton, though there are some trifling variations between the two divisions.

On the borders of the canton are some of the lofty elevations of the Alps, the most remarkable of which is the Titlis, whose snowy peak is 10,700 feet. Next to it are the Wellenstock and the Jockberge, 1000 feet lower; and several of inferior height, as the Geisburg and Bruning on the boundary of Berne; the Nesselstock and the Pilatus on the frontier of Lucerne; and the Engelberg, the Rothstock, and the Brozen on the borders of Uri. The interior has only lower Alps, ranging from 3000 to 5500 feet in height. There are few rivers of much consequence. The most considerable is the Welch, issuing from the lake of Sarnen, and, after uniting with the Aa, losing itself in the lake of the Four Cantons. The chief productions are potatoes and hemp, with some corn in the valleys, but scarcely sufficient for the consumption. On the side of the Alps, and at a great height, in the summer, there is good pasture, and many cows are bred, and their milk made into cheese. The forests yield much timber. The only trade is the export of butter, cheese, hides, chestnuts, and wood, with which are purchased iron, spirits, and the few foreign articles that are used. There are not any manufactures; and besides keeping the flocks and herds, and cutting the wood, there is no occupation except that of fishing on the lakes. There are several mineral springs; one impregnated with sulphur, at Schwendel, is much frequented. The climate is severe, very hot in the short summer, and dreadfully cold in winter. Fruit trees cease to bear above the elevation of 4000 feet; but chestnuts, which are abundant, are to be found higher than that level.

UPPINGHAM, a market-town in the county of Rutland, in the hundred of Martinsley, eighty-nine miles from London and seven from Oakham. It is a clean and well-built town, standing on an eminence, and consisting principally of one long street, with a hospital and a free school, both erected in 1584, and a fine Gothic parish-church. It has a well-frequented market on Wednesday, and two larg fairs, one in March, the other in July. The populatio amounted in 1821 to 1630, and in 1831 to 1757.

UPSALA, one of the provinces of the kingdom of Sweden. It has been formed out of the western part of th ancient province of Upland. It extends in north latitud from 59° 24′ to 60° 39′, and in east longitude from 16° 3 to 18° 17′. It comprehends 2112 square miles, with tw cities, one market-town, and 3546 villages and hamlet The population is 80,926. It is rather an undulating tha a level district, with small groups of hills connected together, which in the north may be almost described a mountains. It extends along the Gulf of Bothnia, bu has no good harbours; but the lake of Malaren, whic forms its southern boundary, and is connected with th sea at Stockholm, provides a good egress for the productions. This lake is connected with a chain of others, which by means of canals, forms a communication between th two seas that bound the eastern and western sides of th kingdom towards the south.

The soil of the southern part of the province is a ric black loam, highly fertile; but in the north, beyond th 60th degree of latitude, it is much less productive. Th chief corn is rye, and in the north barley, with some oats but the whole province usually yields sufficient grain for i consumption. The inhabitants of the northern part subsist almost wholly on oaten bread. It is not favourable t the growth of fruit, except that some cherries are seen, an in most parts abundance of wortle-berries.

In the north there are extensive woods, mostly of pine and firs, with some beeches. The cattle are generall small, but of late the wool of the sheep has been improve by the introduction of Saxon rams. The fisheries, both o the sea and the lakes, afford a supply of food, and give employment to many persons; but the chief occupation arise from the extensive mines of iron that are worked. Th most considerable of them, that of Dannemora, is a prodigious work, and furnishes to commerce the best bar-iron and converts a part into various articles for domestic use.

The capital of the province is the city of the same nam standing on the river Fyrisac, which divides it into tw parts. Upsala is one of the most beautiful old-fashione cities in Europe. It has a castle or palace, the residence o the governor; a cathedral, in which many of the kings hav been interred, and in which there is a fine monument t the memory of the celebrated Linnæus. It is the seat o an archbishop, and likewise of the chief university of th kingdom. This institution, founded in 1478, has a goo library of 50,000 volumes, a fine botanic garden, an astronomical observatory, and the several other aids to stud usually found in universities. The average number o students is 800. The trade of this place is inconsiderable, the manufactures being limited to making snu and tobacco, and weaving coarse linens. The inhabitant amount to 15,000, who mostly depend on the university fo employment and the means of subsistence. In the neighbourhood are many remains of Gothic antiquity. Long 27. 31. 40. E. Lat. 59. 51. 56. N.

UPTON-ON-SEVERN, a market-town of the count of Worcester, in the hundred of Pershore, 109 miles fro London and ten from Worcester. It stands on the righ bank of the Severn, over which is a stone bridge of si arches. The town is well built, and has a very neat church erected in 1758. There is a weekly market on Thursday and three annual fairs; but the chief trade is owing to th navigable river on whose bank it is built. The populatio amounted in 1821 to 2319, and in 1831 to 2343.

URANIA, one of the nine Muses, was supposed to preside over astronomy. She is commonly represented in a azure robe, crowned with stars, and supporting a larg globe with both hands.

URBINO AND PESARO, a delegation or province of t papal dominion in Italy, formed out of the ancient kedom of Urbino. It is bounded on the north by Forli a the republic of St Marino, on the north-east by the riatic Sea, on the south-east by Ancona, on the south-w st by Perugia, and on the west by Tuscany. It ex-t ds over 1733 square miles, comprehending twelve cities, si teen market-towns, and 410 hamlets and villages. The p ulation amounts to 216,071 persons. As it extends o r a great portion of the Apennines, it is necessarily m untainous. It produces, on the sides of the hills and in the v eys, silk, wine, corn, hemp, flax, fruit, cattle, wax, and h ey. The capital is the city of Urbino, which is situated o a hill, and is surrounded with ancient walls and towers. B ng the seat of a bishop, it has a cathedral and also seve-ra other churches, ten monasteries, and six nunneries. A u versity was founded here by Pope Clement X., but it ha disappeared, though a college is still left, and one of th oldest academies of Italy. The population amounts to 1 200 persons. This city is remarkable as the birth-place of he celebrated artist Raphael. Long. 12. 31. 5. E. Lat. 4 43. 36. N.

RGUNGE, or URGHENZ, an extensive tract of terri-to situated on the Lower Oxus, near its junction with th Aral, and between the lake and the Caspian. It is a w and desolate tract, traversed by wandering and pre-da ry hordes of Turkomans. The bulk of the population is ollected in fortified towns, and is maintained by a few fe le spots. The principal of these is called the "region," ar is about four miles in circuit, surrounded by walls of ea h; and the houses are built of the same material. A ma ket is formed by one long street, which is covered ab e, and here the little trade of the surrounding country is rried on. It has been almost ruined by the devasta-tio of war.

RI, a canton of Switzerland, one of the smallest of the wh e confederacy. It is one of the oldest, having gained its ndependence in the year 1307. It is bounded on the no h by the canton of Schwytz, on the east by those of Gl us and the Grisons, on the south by Ticino, and on th west by Berne and Unterwalden. The extent of it is 31 geographical square miles, and the population, which has no like that of most of the other divisions of Switzerland, inc ased of late years, amounted in 1838 to 40,650 indi-vi als. It contains the capital, Altorf, with 1620 inhabi-ta , and eleven divisions, genossamen, or communes. The go rnment is a pure democracy. Every male who has at-tai d his twentieth year is a member of the assembly, in wh h all laws are made and revenues granted, and where the hief, called the landammann, and the other executive off rs, are chosen. As the whole male population are vo s, so they are also soldiers; all are drilled and exer-cis , and formed into militia battalions. The inhabitants are ll of German origin, and use a corrupt patois of that lan age. The courts of law are as popular as the legis-lat e; but there are appeals from inferior to superior tri-bu ls, and, if common report may be trusted, the deci-sio are more directed by bribery and popularity, than by any ixed or just principles. The only religion is that of the hurch of Rome, and the bishop of Constance is the ecc siastical superior, having under him fifteen curates and thr monasteries. In no part of Switzerland are the peo e so miserably fed, clothed, and lodged; in no part are e beggars so numerous and so importunate. The tax pai o the confederative government is 1180 francs, and the con ngent of troops is 236 men. The canton contains some of e highest mountains of Switzerland. In the northern par of the Alps are the Galenstock, 11,330 feet in height; the Sustenshorn, 10,910; and the Spitzleberg, 10,680. In e south is St Gothard, with the points, viz. Fibia, 98 ; Fiendo, 9550; and Prosa, 9250 feet. On the eastern side are to be seen the Scheerhorn, 10,100 feet high; the Windgelle, 9300 feet; and the Bristenstock, 9500. These are almost all surrounded with glaciers, the most remarkable of which is that of St Gothard, over which is one of the great roads to Italy. It is to be supposed that in such an inhospitable region there can be but little cultivation. In the valley of Reuss, the plough is used, but its adoption extends but a little way from the vale. In some other of the vales potatoes are grown, and a few other of the more hardy esculents, but rather in gardens than in farms. Poor as the sustenance of the people is, it is scarcely sufficient for their support; and hence corn is wanted every year from other districts. The chief husbandry is breeding cattle, and the dairy. With cheese, cattle, hides, and some wood, the inhabitants are enabled to pay for the small portions of corn, iron, tobacco, wine, and colonial articles which they consume; and there is now scarcely any other trade. Till lately the road by St Gothard was much used for the transport of goods to and from Italy, and then it was filled with waggons, pack-horses, and their attendants, by which some money was brought into the canton; but the opening of new roads over the Simplon and by the Splugen has attracted much of that commerce into other channels. There are no manufactures, except some of articles which each family prepares for itself.

URIM AND THUMMIM, among the ancient Hebrews, denoted a certain oracular consultation by the high priest, dressed in his robes, and wearing his pectoral or breastplate. Various have been the sentiments of commentators concerning the Urim and Thummim. Josephus and several others maintain that it meant the precious stones set in the high priest's breastplate, which, by extraordinary lustre, made known the will of God to those who consulted him. Dr Spencer believes that the Urim and Thummim were two little golden figures shut up in the pectoral, as in a purse, which gave responses with an articulate voice. In short, there are as many opinions concerning the Urim and Thummim as there are particular authors that have written about them. The safest opinion, according to Broughton, seems to be, that the words Urim and Thummim signify some divine virtue and power annexed to the breastplate of the high priest, by which an oracular answer was obtained from God when he was thus consulted; and that this was called Urim and Thummim, to express the clearness and perfection which these oracular answers always carried with them; for Urim signifies "light," and Thummim "perfection;" these answers not being imperfect and ambiguous, like the heathen oracles, but clear and evident. The use made of the Urim and Thummim was, to consult God in difficult cases relating to the whole state of Israel, and sometimes in cases relating to the king, the sanhedrim, the general of the army, or some other great personage.

URN, a kind of vase, of a roundish form, but swelling in the middle, like the common pitchers; now seldom used but in the way of ornament over chimney-pieces, in buffets, &c. The great use of urns among the ancients was to preserve the ashes of the dead after they were burnt; for which reason they were called *cineraria*, and *urnæ cinerariæ*, and were placed sometimes under the tombstone on which the epitaph was engraved, and sometimes in vaults in their own houses.

URSA, the name of two constellations in the northern hemisphere.

URSULINES, an order of nuns, founded by St Angela of Brescia, in the year 1537, and so called from St Ursula, to whom they were dedicated.

URUMEA. See OUROOMIA.

USANCE is a determined time fixed for the payment of bills of exchange, reckoned either from the day of the bills being accepted, or from the day of their date; and thus called because regulated by the usage and custom of the places on which they are drawn.

USE, in *Law*, the profit or benefit of lands and tenements, or a trust and confidence reposed in a person for the holding of lands, &c., that he to whose use the trust is made shall receive the profits.

USHANT, an island on the coast of France, in the department of Finisterre and arrondissement of Brest. It is a lofty district, surrounded with steep rocks, but to navigators is an important point when approaching from the west. It is about eighteen miles in compass. It contains, besides the garrison, 1650 inhabitants, subsisting by agriculture and fishing. There is a light-house on the island. Long. 5. 9. 11. W. Lat. 48. 23. 8. N.

Ushant, or *Ouessant*, a small island in the Pacific Ocean, discovered in 1768, by M. Bougainville, near the coast of New Guinea. Long. 146. 33. E. Lat. 11. 5. S.

USHER, an officer or servant who has the care and direction of the door of a court, hall, chamber, or the like.

Usher *of the Black Rod*, the eldest of the gentlemen ushers, daily waiters at court, whose duty is to bear the rod before the queen at the feast of St George, and other solemnities.

USIDSCHA, or Usicza, a city of Turkey in Europe, in the province of Semendria. It is situated in a beautiful valley, watered by a small river, which divides it into two parts. It is surrounded by walls, has several Greek churches, and 6000 inhabitants, mostly of that nation, who carry on considerable trade.

USK, a market-town in the hundred of the same name, in the county of Monmouth, 144 miles from London. It takes the name of the river on which it is built. On a hill near it are the ruins of its ancient castle. The church is of Norman construction, built in the form of a cathedral. The priory, to which it appertained, is now in ruins. Usk is a borough, and, in conjunction with Monmouth and Newport, returns one member to the House of Commons. A market is held on Monday. The population amounted in 1821 to 989, and in 1831 to 1160.

Usk, a river of Wales, which rises on the west of Brecknockshire, and runs south-east through that county and Monmouthshire, falling into the mouth of the Severn.

USMAN, a circle of the Russian government of Tambow, extending in north latitude from 51° 58′ to 52° 23′, and in east longitude from 39° 14′ to 41° 24′. It is watered by the rivers Usman and Woronesh, is 1804 square miles in extent, and contains 54,600 inhabitants. Numerous herds of horned cattle are depastured in its rich meadows, and the attendance on them is the chief occupation. The capital is a city of the same name, situated at the junction of the two rivers before mentioned. It has four churches, 474 houses, and 3140 inhabitants. It is 778 miles distant from St Petersburg. Long. 39. 40. E. Lat. 53. 5. N.

USTEE, a town of Hindustan, belonging to the Nagpoor Mahrattas, in the province of Berar, fifty miles east from Ellichpoor. Long. 75. 52. E. Lat. 21. 18. N.

USTICA, one of the Lipari group of islands, in the Tyrrhenian Sea, belonging to the kingdom of Naples. It is the Osteodes, or Island of Bones, of the ancients, and is about forty miles north by west from Palermo. It has in it the town of Santa Maria, with a haven of sufficient capacity for the feluccas that trade to it. The inhabitants amount to about 1700, exclusive of the garrison. They are more civilized than the people of the other islands of the group, from having direct weekly intercourse with the capital. The island is composed of volcanic substances, derived from hornstone base. The soil is an aggregate of decomposed scoriæ, tufa, sand, and ashes. It is extremely fertile, but liable to be washed away, especially from the sides of the hill, by heavy rains. From the nature of these materials, there are no springs; rain-water is therefore kept in capacious cisterns. As heavy dews fall, the trees bear abundance of fruit; and the whole ground is well cultivated, and yields very good wine. Charcoal and firewood are supplied, chiefly from the roots of the olive tree, from Cefalu and Palermo.

USTJUG-WELIKI, a circle of the Russian province Wologda, extending in north latitude from 59° 40′ to 64° 40′, and in east longitude from 43° 19′ to 48° 40′. It is bounded on the north by Solwytschegodsk, on the east by Ustsysolsk, on the south-east by Wiatka, on the south by Nikolsk, and on the west by Totma and Welsk. It comprehends 8338 square miles, and contains 68,350 inhabitants. It is chiefly an elevated plain, the source of most of those streams which unite to form the river Dwina. The climate is raw and the soil poor. It produces flax and hemp, some barley, but the chief products are timber, tar, and pitch. The capital is the city of the same name, situated on the river Suchona, at its junction with the Jug. It is a large place, built after the old Russian fashion, containing five monasteries, twenty-three churches, 2000 houses, and 11,500 inhabitants, employed in coarse manufactures of linen and cloth. It is 1076 miles from St Petersburg. Long. 45. 43. E. Lat. 60. 10. N.

USTJUSHNA, a circle of the Russian government of Novogorod. It extends in north latitude from 58° 28′ to 59° 55′, and in east longitude from 34° 11′ to 37° 15′. Only one tenth of the surface is used for agriculture and pasture; about three tenths consist of wood, and the rest is quite waste. It contains a city, a market-town, 550 villages or hamlets, and 45,300 inhabitants. The capital is a city of the same name, situated on the river Wolga, in a district where are some rich mines of iron. It contains 460 houses, with 3130 inhabitants, who trade on the river, and carry on fisheries. It is 372 miles from St Petersburg. Long. 36. 26. E. Lat. 58. 53. N.

USTSYSOLSK, a circle of the Russian province of Wologda, extending in north latitude from 59° 30′ to 64° 56′, and in east longitude from 47° 19′ to 57° 34′. It comprehends the vast space of 66,814 square miles, with not more than 36,000 inhabitants. The soil is very sterile, yielding no other corn than a little barley. The chief productions are those of the forests, and the only part of them that will bear the cost of conveyance consists of pitch, tar, and the furs of wild animals. The capital is the city of the same name, situated on the river Sysolka, and containing 360 houses, with 1940 inhabitants, who trade chiefly in peltry. It is 1345 miles from St Petersburg. Long. 49. 16. E. Lat. 60. 37. N.

USUFRUCT, in the *Civil Law*, the use or enjoyment of any lands or tenements, or the right of receiving the fruits and profits of an inheritance, or other thing, without a power of alienating or changing the property of it.

USURER, a person charged with a habit or act of usury.

USURPATION, in *Law*, is an injurious using or enjoyment of a thing for continuance of time, that belongs of right to another.

USURY, an unlawful contract upon the loan of money, to receive the same again with exorbitant increase. By statute 37 Hen. VIII. c. 9, the rate of interest was fixed at ten per cent. per annum; which the statute 13 Eliz. c. 8, confirms, and ordains that all brokers shall be guilty of a *præmunire* who transact any contracts for more, and the securities themselves shall be void. The statute 21 Jac. I. c. 17, reduced interest to eight per cent.; and it having been lowered in 1650, during the usurpation, to six per cent., the same reduction was re-enacted after the restoration by statute 12 Car. II. c. 13; and the statute 12 Annæ, st. 2, c. 16, reduced it to five per cent. Not only all contracts for taking more were in themselves utterly void, but also the lender was to forfeit treble the sum of money b rowed. If any scrivener or broker took more than five s lings per cent. procuration-money, or more than twelve p ce for making a bond, he was to forfeit L.20, with costs, a l to suffer imprisonment for half a year. By 3 & 4 Will. I c. 98, § 7, bills not having more than three months t un were exempted from the operation of the laws against u ry. By 1 Vict. c. 80, the exemption was extended to b s payable at twelve months; and the operation of the a was limited to the first day of January 1840. By 2 & 3 Vict. c. 37, it is enacted, that bills of exchange and c tracts for loans or forbearance of money above L.10, s ll not be affected by the usury laws. Five per cent. is till left as the legal interest of money, unless it shall a ear that any different rate was agreed to between the p ties. All previous enactments relative to pawnbrokers a to remain in full force. This act is to continue in force ti the first day of January 1842.

JTICA, a town of ancient Africa Propria, on the Med erranean. It was founded by a Tyrian colony, and was o er than Carthage; its name, according to Bochart, den ing *old*. After the destruction of Carthage, it became t capital of all the Roman territories in Africa. Accordi to Strabo, it stood on the same bay with Carthage, at o of the promontories called Apollonium, bounding the b on the west side, the other to the east, called Hermeia, b ng at Carthage. Utica became famous by the death of o, called Cato Uticensis.

UTRECHT, one of the provinces of the kingdom of I lland. It extends in north latitude from 51° 58′ to 52° 1, and in east longitude from 4° 41′ to 5° 32′. It is nded on the north by the province of Holland and by t Zuyder Zee, on the east by Gueldres, on the south by eldres and by Holland, and on the west by Holland. It ntains 535 square miles, is divided into two circles, those Utrecht and Amersfort, and the population in 1838 ounted to 140,574. About two thirds of the people of the Calvinist church, and one third adhere to the mish communion. In the northern and western parts, l on the borders of the Lech, the land is low and flat; t in the eastern part, between the towns of Utrecht and nersfort, is a range of hills of slight elevation. The soil the low parts is rich and fertile, having, like Holland, st productive meadows, and ploughed land yielding undant crops of corn. Here and there are some woods, ed with shrubs rather than trees, and several extensive aths. The chief occupation is agriculture, with breeding tle, and the making of butter and cheese. The province s a surplus of corn, and that, with the products of the ry, forms the chief exports. Besides these, they send to er districts honey, wax, wool, tobacco, madder, and some er articles. The tobacco is much valued, especially that Amersfort, though it is chiefly mixed with the tobacco America, to give it a peculiar flavour. There are in e towns manufactories of woollen, silk, linen, and cotton ods. Abundance of fuel is supplied by the turf, and nsmitted with facility by means of canals. The capital the province is the city of the same name, as it also is a circle subdivided into nine cantons. It stands in a plea- nt situation on the Old Rhine, which has here become a all stream, by the separation from it of the great body of water. It is however still navigable for small craft, d is connected by a canal with Amsterdam. The en- ons, especially near the river, are adorned by many autiful country-seats, belonging to the rich class of mer- ants of Amsterdam; and the gardens around them are d out with great care and taste. The city is large, well ilt, and fortified; but its defences have been neglected, d are now useless. The most remarkable buildings are, e Dome Kirk, with its lofty tower, from which is an ex- nsive prospect; the royal palace, where, in 1579, the ion with Holland was signed, and the peace of 1713, which bears the name of the city; the town-hall, the mint, and the foundling hospital. There are fifteen churches, seven of which belong to the Calvinists, three to the Catholics, and one each to the French Protestants, to the English, to the Remonstrants, to the Lutherans, and to the Mennonites. There is a celebrated university, with nineteen professors and about 600 students; and attached to it is a library, a botanic garden, an observatory, and several museums. The inhabitants amounted in 1838 to 20,390 males and 23,017 females, making together 43,407 persons. The commerce has much declined from its former state, but of late years has received a revival from the introduction of new articles of manufacture, especially those of cotton, of silk, and of goods composed of these two materials together. Here they also make some needles, stockings, serges, refined sugar, and sailcloth. Long. 5. 1. 12. E. Lat. 52. 5. 12. N.

UTTOXETER, a market-town of the hundred of Totmonslow, in the county of Stafford, 135 miles from London. It stands on a rising ground on the river Dove, in a district abounding with woods. It is moderately well built; and the church is distinguished by the loftiness of its spire. There is much trade in some branches of hardware, and, by means of the navigable canals, much interchange of commodities with all parts of the kingdom. There is a well-frequented market on Wednesday, and four annual fairs. The population amounted in 1821 to 4658, and in 1831 to 4864.

UVA, a lake of Asiatic Russia, in the government of Tobolsk, about twenty-eight miles in circumference. It is sixty-eight miles south-east of Tobolsk.

UXBRIDGE, a market-town of the county of Middlesex, fifteen miles from London. It is a part of the parish of Hillingdon, in the hundred of Elthorne. It is tolerably built, well paved, and lighted. The river Colne here joins the Grand Junction Canal, and thus forms a water communication with the metropolis. There is an extensive corn market on Thursday, and many mills in the vicinity are employed in grinding it, and in preparing the flour for the supply of London. This place is remarkable as the scene of the treaty attempted between Charles I. and his parliament. The house then used has been preserved, but is now occupied as an inn. Near the town are the remains, on Heiling Down, of an ancient encampment, commonly supposed to have been the work of the Britons. This town gives the title of earl to the eldest son of the marquis of Anglesea. The population amounted in 1821 to 2750, and in 1831 to 3043.

UZ, or UTZ, the country and place of residence of Job. In the genealogy of the patriarchs, there are three persons called Uz, any of whom might give this district its name. The first was the grandson of Shem, by his son Aram (Gen. xxii. 23), who, according to Josephus, occupied the Trachonitis and Damascus, to the north of Palestine; but Job was among the sons of the East. Another Uz was the son of Nahor, Abraham's brother (Gen. x. 21), who, after passing the Euphrates, appears to have removed from Haran of Mesopotamia to Arabia Deserta. The third Uz was a Horite, from Mount Seir (Gen. xxxvi. 28), and thus not of Eber's posterity. Now the question is, from which of these the country of Job took its name. Not from the first, as is already shown; nor from the second, because his country is always called Seir, or Edom, never Uz; and then called a south, not an east, country, in Scripture. It therefore remains that we look for the country and place of residence of Job in Arabia Deserta, for which there are very probable reasons. The plunderers of Job are called Chaldeans and Sabeans, next neighbours to him. These Sabeans came not from Arabia Felix, but from a nearer Sabe in Arabia Deserta (Ptolemy); and his friends, except Eliphaz the Themanite, were of Arabia Deserta.

V.

V, Vaccination.

V or v is properly a consonant, and as such is placed before all the vowels; as in *vacant*, *venal*, *vibrate*, &c. Though the letters v and u always had two sounds, they had only the form v till the beginning of the fourth century, when the other form was introduced, the inconvenience of expressing two different sounds by the same letter having long before been observed. In numerals V stands for five; and with a dash added at top, thus $\bar{V}$, it signifies 5000.

In abbreviations, among the Romans, V. A. stood for *veterani assignati;* V. B. *viro bono;* V. B. A. *viri boni arbitratu;* V. B. F. *vir bonæ fidei;* V. C. *vir consularis;* V. C. C. F. *vale, conjux charissime, feliciter;* V. D. D. *voto dedicatur;* V. G. *verbi gratia;* Vir. Ve. *virgo vestalis;* VL. *videlicet;* V. N. *quinto nonarum.*

VACCINATION, (from *vacca*, a cow), is the artificial production of a disease, originally obtained from the cow, (cow-pox), by bringing the matter of that disease in contact with the living fibre.

To Dr. Edward Jenner we are indebted for the discovery of vaccination. His attention was first directed to the subject by the popular belief which existed in Gloucestershire, where he resided, that those who were infected with matter from the sores on the udder of the cow, were ever after secured from the contagion of small-pox. It was not, however, till the 14th of May 1796, that he made it the subject of direct experiment, by taking matter from the sore on the hand of a dairymaid who had contracted cow-pox from the udders of her master's cows, and applying it, by means of two superficial incisions, to the arm of a boy. Pustules somewhat similar to those of small-pox, but darker in their hue, and filled with a limpid fluid, were produced, and became surrounded with an erysipelatous or red circle, but the whole died away, leaving on the inoculated part scabs and subsequent eschars, without producing any other inconvenience. On the seventh day after the operation, the boy complained of some uneasiness in the arm-pit; on the ninth he became chilly, had headach, loss of appetite, and was otherwise indisposed, and passed a restless night, but was well by next day. As the object of the experiment was to ascertain whether the cow-pox gave immunity from the small-pox, he was on the 1st of July inoculated with small-pox matter, but no disease was produced; and the same result was obtained when this was repeated some months afterwards. Numerous experiments of the same kind were afterwards made; and they ended in establishing the fact that the matter of cow-pox protected the human body from being acted on by the infection of small-pox, while it was itself a mild and safe disease, exciting little more constitutional disturbance than what resulted from the local sore.

Dr. Jenner accounted for this singular fact, by asserting that cow-pox was nothing else than small-pox modified, or deprived of all its noxious qualities, by having passed through the system of the cow; and that the disease in the heel of the horse, called grease, which he showed was capable of producing the vaccine vesicle in the cow, was also but a variety of the same disease. In fact, he at first regarded both small-pox and cow-pox as originally derived from the horse.

The publication of such an interesting fact did not fail to excite general attention; and, accordingly, the very same year in which Dr. Jenner's Inquiry made its appearance, Dr. Pearson published the results of his investigations, which tended to confirm the opinion advanced by Dr. Jenner as to the anti-variolous powers of the cow-pox. In two points alone did he dissent. He regarded cow-pox and small-pox as two very different diseases, and denied that the cow-pox could be produced by the matter of the diseased heel of the horse; and he was supported in his opinion by the inquiries of Sir Isaac Pennington, the arguments of Dr. Parr, and the experiments of Dr. Woodville, and of Mr. Simmons.

Other experimentalists were, however, much more successful in confirming the opinion of Dr. Jenner as to the analogy or rather identity of the disease of the horse's heel and the cow-pox. Mr. Tanner succeeded in communicating the cow-pox to the cow, by inserting on the udder some liquid matter taken from the diseased heel of the horse; and the experiments of Mr. Lupton and Dr. John Loy corroborated the same fact. Dr. Loy, indeed, found that even the equine matter produced in man as perfect vaccine vesicles, as that derived from the cow itself, and afforded equal protection from the infection of small-pox. These conclusions have been confirmed by subsequent experimentalists both in this country and on the continent, so that it is now to be regarded as an established fact, that grease and cow-pox are the same complaint, modified by the constitution of the animals in which they occur.

Dr. Woodville of the London Small-Pox Hospital lent his aid to ascertain, by direct experiment on a large scale, whether the introduction of the mild disease, cow-pox, was worthy of the encomiums bestowed upon it by Dr. Jenner and Dr. Pearson, and whether it really guarded the system from a subsequent attack of that loathsome and fatal disease, the small-pox. The results of these experiments were published in 1799, by which time he had vaccinated six hundred individuals. In most of these cases, small-pox inoculation had been performed at a subsequent period, to test the efficacy of the protective power of the cow-pox, but not one of them took the small-pox. An anomalous occurrence, however, showed itself in nearly three-fifths of the patients vaccinated at the Small-Pox Hospital. Pustular eruptions, more or less numerous, resembling those of small-pox, appeared on various parts of the body, in some cases maturating much in the same way as the pustules do in that disease, in others fading away without proceeding to the formation of matter. Dr. Jenner, at the time when the circumstance occurred, endeavoured to explain it, by supposing that it was owing to some peculiarity in the air which these patients breathed, or to a contamination of the original cow-pox matter with small-pox. That it could not be owing to contamination with small-pox matter, Dr. Woodville showed from the fact, that the same matter, when employed for the vaccination of individuals out of the Small-Pox Hospital, did not produce these same pustular eruptions; and some of the identical matter sent to the country, and used in vaccinating one thousand individuals, only produced pustular eruptions in two cases. Dr. Woodville, therefore, very justly drew the inference, that the cases vaccinated at the Small-Pox Hospital differed from those vaccinated elsewhere, in being placed in the centre of a variolated atmosphere, to the action of which the pustular eruption was to be ascribed; a statement which was in a manner proved at the time by the fact, that though at first nearly three-fifths of all the cases vaccinated showed pustular eruptions, yet the eruptions afterwards diminished so much, that of the last hundred cases which he published in his first Reports, only seven were thus affected

S sequent observation has shown that this was in reality th true explanation of the fact.

Dr. Woodville considered small-pox and cow-pox as ve closely allied in their nature, indeed, "to a very pr cipal point essentially the same," and consequently reco mended the general adoption of cow-pox, as an effectu preservative from the infection of small-pox, as perfectly sa and free from danger, and incapable of being propagate by infectious effluvia. This last he considered a very st ng circumstance in its favour, since small-pox, even in its mildest form, as produced by inoculation, tended greatly to well the bills of mortality, by spreading the infection from th sick to the healthy.

was during the progress of Dr. Woodville's experiments at he Small-Pox Hospital that the merits of vaccination be n to be appreciated, and the practice of it generally in oduced into all parts of this country; and the publication of is Observations in 1800 may be regarded as marking th epoch. At this period, indeed, the efficacy of vaccinatic as an anti-variolous agent was so generally admitted, an the practice so universally adopted, that, in the course of few months, its benefits were extended to many thousa persons in all parts of this island, and matter found its way to France, Italy, Germany, Holland, Turkey, most of r colonies, and the United States of North America. N merous were the publications, in all languages, announcing th success of the practice; and almost every one agreed in th that it gave as perfect protection from the infection of sm ll-pox, as if the individual had once had the natural or in ulated disease.

Many of the partizans of vaccination, however, went much fa her than this, and asserted that those who had once gone th ugh the vaccine disease, were at no subsequent period of heir lives liable to take small-pox. When, therefore, ca s of small-pox did occur after vaccination, they endeave ed to explain away the fact, by asserting that it was n true small-pox, or that the individual had not gone th ugh the true, but a spurious vaccine disease. This was, in ed, claiming for vaccination a power which was not po essed by any other disease. There is a class of disea s which usually occur but once during the course of life, bu though a second attack is not a common occurrence, st it is every now and then met with; and there are very fe medical men of any standing in their profession who ha not met with cases of second attacks of measles, scarle fever, small-pox, typhus, &c. Dr. Thomson of Edinbu gh, in his work on the Varioloid Epidemic of 1818, was the fi to point out this clearly with regard to small-pox; and ha the circumstance been duly attended to when vaccinati was first introduced, it would have prevented much of he controversy which has since arisen. It was unre onable to expect from vaccination a protective power gr ter than that afforded by small-pox itself; and yet it was fr the advocates of vaccination advancing this doctrine, — doctrine apparently borne out by the perfect immunity at ded to so many thousands vaccinated in all parts of E ope on its first introduction,—that others, who had seen ca s of small-pox after it, were led to deny altogether its an -variolous power, or at least to affirm that it only gave imm nity from the disease for a very limited number of years.

was not, however, till the year 1818, that the true valu of the protective powers of vaccination was properly un erstood. During the years 1816–17–18, small-pox raged ep emically in various parts of Europe, and attacked both th vaccinated and variolated, as well as those who had ne her had cow-pox nor small-pox. Chicken-pox was at th same time extremely prevalent, and the pheuomena of th two diseases were found to be frequently and generally in rchanged. Dr. Hodenpyl of Rotterdam, Dr. Thomson of Edinburgh, and MM. Berard and De Lavit of Montpelli who all described this epidemic, agreed in regarding small-pox and chicken-pox as the same disease, which could be shown to originate from the same source. But the most important fact, and the one most interesting to humanity, was the ascertaining the comparative mortality of small-pox, when it attacked these three classes:—1st, the vaccinated; 2d, the variolated, *i.e.* those who had small-pox; and, 3d, those who had neither been vaccinated nor had small-pox. The conclusions at which these different writers arrived were nearly the same. Of those who had neither had cow-pox nor small-pox, 1 out of every 4 who were seized with the disease died; of those who had small-pox naturally, or by inoculation, 1 out of every 25 to 1 in 75 died; while of those who had been vaccinated, and were afterwards seized with small-pox, not more than 1 in 330 cases died: thus showing the great superiority of vaccination even to the small-pox itself, in protecting the system from the fatal effects of a second attack. Nor is it difficult to understand how this should happen. Small-pox is a disease not only very fatal, as proved by its cutting off a fourth of all whom it attacks, but it disfigures or renders infirm from an eighth to a tenth of those who recover. Its action is besides found to develope any latent disease, but particularly any scrofulous tendency which may exist in the constitution, and is thus indirectly the cause of death to a much larger portion of the human race than what at first sight appears. It is not therefore to be wondered at, that small-pox, attacking for the second time a constitution thus enfeebled, should cause a much greater proportion of deaths than takes place when it occurs after vaccination; for no fact is more firmly established than this, that vaccination neither developes any latent malady, nor engenders a predisposition to any particular disease.

The fact above mentioned, of the comparative mortality of the three classes, viz. the vaccinated, the variolated, and the non-vaccinated, has been, since 1818, repeatedly demonstrated. One of the most accurate and interesting details, and one which ought to set the point for ever at rest, is that given by M. Bousquet in his *Traité de la Vaccine*, as having occurred at Marseille during the epidemic small-pox of 1825. The population of Marseille, amounting to 40,000, may be divided into three classes, of which the respective numbers stand thus: 30,000 vaccinated; 8000 neither vaccinated nor variolated; and 2000 variolated, that is, who had the small-pox either naturally or by inoculation. Of the 30,000 vaccinated, about 2000 were seized with the prevalent small-pox epidemic, of which number twenty died, or one for every hundred affected. Of the 2000 variolated, twenty were attacked, and four died, or one in every five cases. Of the 8000 non-vaccinated, 4000 were affected, and of this number 1000 died, or one out of every four cases. From this it follows, that one-half of the non-vaccinated, 1–15th of the vaccinated, and only 1–100th of the variolated, took the disease. But such was the difference in the comparative severity of the attack in the vaccinated and variolated, that while the variolated part of the population were cut off in the proportion of one out of every 500, the vaccinated part of the population only lost one out of every 1500; or, in other words, of an equal number of variolated and vaccinated cases, three variolated died from the second attack, for every one who died of the disease after vaccination.

Many similar instances might be quoted; all of them demonstrating the very great security to the individual, and the saving of life to the community, afforded by the introduction of vaccination. This is a subject, indeed, which has engaged the attention of political economists; and as it has been calculated that in Britain alone, before the introduction of vaccination, no fewer than 35,000 were annually cut off by small-pox, while in France the deaths from that cause amounted to 85,685, and proportionally large numbers occurred in other parts of Europe and America, the saving

Vaccination.

of life effected by this invaluable discovery must be immense.

Though the benefits of vaccination were thus clearly proved, the public confidence in it has been attempted to be shaken by raising the outcry, that the vaccine virus, if it really possesses anti-variolous powers, loses them as life advances; so that, at the end of a few years, those vaccinated individuals are as liable to the attack of small-pox as if they had never been affected by the disease. It is fortunately an easy matter to trace such an opinion to its true sources; namely, to a disbelief in the fact, that small-pox can occur twice in the same individual; and to a disbelief in the identity of small-pox and cow-pox. Those holding such opinions as these, see every thing through the mist of prejudice, and represent every instance of the occurrence of small-pox after vaccination as an additional proof of the correctness of their theory; shutting their eyes to the facts daily happening around them, that a second attack of small-pox is not only by no means a very rare occurrence, but that it is a much more dangerous and fatal disease than small-pox after vaccination, cutting off at least three times as many victims.

As the first of these objections has, it is conceived, been satisfactorily shown to rest on no solid grounds, we are next to examine whether the second stands on any better foundation.

Every writer who has opposed vaccination, whatever may have been his other grounds of objection, has constantly set out with the proposition, that there are certain diseases which occur but once in the course of life, and which effect some unknown change on the constitution, rendering it unsusceptible of a second attack of the same disease. As they regard small-pox and cow-pox as two distinct diseases, they cannot imagine how the one disease should guard the human frame from the ravages of the other; and one of the latest writers on the subject of vaccination, Dr. G. Gregory of the Small-Pox Hospital, London, actually declares, that "vaccination is not small-pox, but just the reverse—the antagonist principle." In order to answer such an objection, all that is requisite is, to show that small-pox and cow-pox are really identical, the latter only modified by having passed through the system of the cow, as originally advanced by Dr. Jenner, the father of vaccination.

It was announced so early as 1802, by Professor Viborg of Copenhagen, that, at Berlin, small-pox was communicated to the cow by inoculation; but the details of these experiments do not appear to have reached this country, and all attempts to repeat them here have failed. It was not till 1830, that any detailed account of successful experiments of this kind were published, when Dr. Sonderland of Barmen announced that he could produce the true vaccine disease in the cow at pleasure, by covering the animal with the blankets from the bed of a patient who had died of small-pox, and by hanging them up around it, that it might breathe the effluvia arising from them. In a few days, he says, the animal became sick, and pustules appeared on the udder and other parts, precisely similar to the cow-pox vesicles, and filled, like them, with lymph. This lymph, transferred to the human subject, he found to produce the genuine vaccine vesicle, together with the usual constitutional disturbance, and to protect the individual from the small-pox virus or contagion. In fact, such a change was effected on the small-pox matter, during its transit through the system of the cow, that it was converted from a virulent and fatal into a mild and safe disease.

The announcement of this curious experiment incited others to repeat it, though without success; and it was not till 1839 that Mr. Robert Ceely, surgeon to the Buckinghamshire Infirmary, succeeded in proving the identity of the two diseases, by communicating small-pox by inoculation to the cow, and finding it produce the true cow-pox disease. He however failed to communicate small-pox to the cow after the manner found successful by Dr. Sonderland. Mr. Ceely inoculated heifers with the matter of small-pox, and found it to produce genuine vaccine vesicles, which ran their course like the natural or inoculated cow-pox, and furnished limpid lymph for vaccination. The lymph was employed in vaccinating many children, and differed in no respects from that obtained from the natural cow-pox vesicle of the cow. It ran the same course when introduced by punctures on the arm; did not give rise to any eruption on the skin, any more than primary vaccine lymph; and afforded equal protection against small-pox, as found by exposing the children to the small-pox effluvium, and also by inoculating them with small-pox virus; in fact, it did not in any respect differ from ordinary vaccine lymph, as obtained from the natural vaccine vesicle.

Nothing could be more satisfactory than the result of such an experiment. For here it is proved, beyond the possibility of a doubt, that small-pox and cow-pox are but varieties of the same disease. It is therefore no longer to be regarded as an anomaly, that cow-pox should protect the system from an attack of small-pox, but it is in beautiful accordance with what has been generally admitted to be a law in nature, that certain diseases, once undergone, protect the system from a subsequent attack.

The chief objection to vaccination having been, it is hoped, answered satisfactorily, it only remains to show, that the protective powers of vaccination do not wear out of the system as life advances, any more than those of small-pox itself. This is a most important inquiry; as nothing is more likely to prove hurtful to the cause of vaccination, and render the public careless of securing to themselves its benefits, than the belief, that they would require to submit to revaccination every ten or fifteen years, and that at no period of their lives they could with certainty reckon on escaping the small-pox.

Starting from the point which has been proved, that the cow-pox and the small-pox are the same disease, all analogy shows that the system having once passed through this disease, is not in general susceptible of a second attack. More than forty years have now elapsed since vaccination was introduced; and if, as the opponents of vaccination assert, its anti-variolous powers wore out of the system in a few years, why does it happen that small-pox is not now as deadly a scourge among the grown population, as it was before the introduction of vaccination? It has not been for want of epidemics of small-pox that the grown population has escaped for so many years. At Marseille, after a lapse of twenty-five years, it was found that the protective powers were not in the least diminished. Of the 30,000 who had undergone vaccination in that city, only twenty fell victims to the small-pox, or one out of every 1500 individuals: while of the 8000 who had not been vaccinated, no fewer than 1000 died, or one out of every eight persons. Here was no falling off of the protective power of vaccination after twenty-five years. Nay, the security afforded by vaccination was even greater than that of small-pox itself, for out of a population of 2000 who had had small-pox, no fewer than four died, or one out of every 500 individuals; exactly three times as many as those who had been protected by vaccination. But this is only one of many similar instances which might be produced.

It having been found, that from a sixth to a third of those who have been vaccinated are capable of receiving vaccination a second time, after the lapse of a greater or lesser number of months or years, the opponents of vaccination adduce this as an additional argument to prove that its anti-variolous powers wear out of the system. But such assertions will not bear a moment's serious reflection. Allowing, for the sake of argument, that all those who could be re-vaccinated successfully, would be equally liable to an attack small-pox, *if exposed to its influence*, (which they are not, as it has been clearly proved by experiment that individuals may be successfully revaccinated, and yet be unsusceptible of the poison of small-pox,) what would be the result? Their chances of recovery would be as 100 to one, that of dying as one to 100. Or, in other words, if 100 were attacked with small-pox after vaccination, only one would die; whereas, if 100 who had formerly had small-pox were again attacked, no fewer than twenty would die. Now this is stating the facts in their most favourable light for the opponents of vaccination, as, according to what has occurred in several of the variolous epidemics, only one of the vaccinated has died out of 330 individuals attacked; but either of the statements is quite sufficient to prove the immense superiority of vaccination to inoculation, and also the fact, that the security afforded does not decrease with the advance of life.

The Royal Academy of Medicine of France, after the fullest inquiry into this subject, have arrived at the conclusion, that vaccination gives, in general, perfect protection from a subsequent attack of small-pox,—a protection fully as perfect as if the individual had gone through the small-pox itself; and when the government applied to them in 1839, to ask their advice as to whether the students at the different public schools and colleges ought to be revaccinated before leaving them, they returned for answer that they ought not, as having been once vaccinated gave protection from small-pox for the remainder of life.

It is extremely satisfactory to learn that all extended inquiries have led to the same result, that vaccination gives full protection from small-pox for life. Too little attention has, in this country, been paid to the statistics of disease, and also to vaccination, to give anything like accurate results as to the effects of vaccination in diminishing the mortality from small-pox; but in several countries of the continent of Europe, the same remissness has not been shown, and there the advantages of the general introduction of vaccination is demonstrated. One instance may suffice for illustration. In Sweden, in the year 1779, no fewer than 15,000 persons were cut off by small-pox; and in 1800, the year before the introduction of vaccination, 12,000 fell victims to the same disease. Great exertions were now made to introduce and carry into effect the beneficial practice of vaccination, when the mortality from small-pox yearly diminished, till it fell so low as eleven in the year 1822, and thirty-seven in the year 1823. Since then, "for a period of eight years, not a single case of small-pox has occurred in the dominions of his Swedish majesty: the whole inhabitants had been vaccinated."

If the anti-variolous powers of vaccination failed after a certain number of years, say ten or fifteen, instead of having, as above stated, an annually decreasing number of small-pox cases, we should have seen them occurring in a gradually increasing ratio. But as the practice has now stood the test of a whole generation, and has been found to be as effectually protective at the end of that long period as at the beginning, we may safely acquiesce in the conclusion of the French Academy of Medicine. The truth is, that the ratio of mortality from small-pox, after vaccination, is greatly less than that of almost any disease to which the human frame is subject; and were vaccination as generally practised, and as carefully attended to, in this and other countries, as in Sweden, the sanguine hope of Jenner might yet be fulfilled, that the small-pox might be quite extinguished. (C. M.)

VACS, a city of the Austrian kingdom of Hungary, in the province of the Upper Danube, the capital of a circle of the same name, but called by the Germans Waizen. It stands on the river Danube, on a fruitful plain. It is the seat of a bishop, has a cathedral and several other churches, two monasteries, a college, an orphan house, and a military academy. It contains 800 houses, with 5430 inhabitants, who trade largely in corn, cattle, and wine. Lat. 47. 47. Long. 19. 2. 35. E.

VACUUM, in *Philosophy*, denotes a space void of all matter or body. It has been disputed whether there be in nature a perfect vacuum; but if bodies consist of material solid atoms, it is evident that there must be vacuities, or motion would be impossible. We can even produce something very near a vacuum in the receiver of an air-pump, and in the Toricellian tube.

VAGABOND, or VAGRANT, one who wanders illegally, without a settled habitation. Such persons are cognizable by the laws.

VAILLANT, JEAN FOY, to whom, according to Voltaire, France was indebted for the science of medals, and Louis XIV. for one half of his cabinet, was born at Beauvais on the 24th of May 1632. At the age of three, he lost his father, and the charge of his education was undertaken by one of his maternal uncles. This uncle, who belonged to the magistracy, and who had destined him for his successor, died after bequeathing him his name and a part of his fortune; and being thus left to follow his own inclination, he relinquished the study of law for that of physic, and took a doctor's degree. He engaged in practice at Beauvais, but was accidentally drawn into a new department of study, which he prosecuted with great ardour during the remainder of his life. A farmer of that vicinity had found a great quantity of ancient coins, and Vaillant at first inspected them in a cursory manner; but perceiving that they bore a reference to events either forgotten or inaccurately detailed by historians, he was induced to resume their examination with deep attention, and he succeeded in explaining them with a facility which is generally the result of long experience. Having afterwards made a visit to Paris, he became known to Seguin, eminent for his numismatic skill, and astonished him by the extent of his knowledge. He was introduced to other men of learning; and the minister Colbert proposed to employ him in travelling to collect medals for the royal cabinet. He accepted of the offer, and after travelling into Italy, Greece, Egypt, and Persia, he returned with so many medals as made the king's cabinet superior to any in Europe. In one of his voyages, in 1674, the ship was taken by an Algerine corsair. After a captivity of nearly five months, he was permitted to return to France, and received at the same time twenty gold medals which had been taken from him. He embarked in a vessel bound for Marseille, and was carried with a favourable wind for two days, when another corsair appeared, which, in spite of all the sail they could make, bore down upon them within the reach of cannon shot. Vaillant, dreading the miseries of a fresh slavery, resolved at all events to secure the medals which he had recovered at Algiers, and therefore swallowed them. But a sudden change of the wind freed them from this adversary, and cast them upon the coast of Catalonia; and after expecting to run aground every moment, they at length fell among the sands at the mouth of the Rhone. He reached the shore in a skiff, but felt himself extremely incommoded with the medals he had swallowed, which might weigh altogether five or six ounces, and therefore did not pass like Scarborough waters. He had recourse to a couple of physicians, who were a little puzzled with the singularity of his case; however, nature relieved him from time to time, and he found himself in possession of the greatest part of his treasure when he arrived at Lyon. Among his collection was an Otho, valuable for its rarity. He was much caressed on his return; and when Louis XIV. gave a new form to the Academy of Inscriptions in 1701, Vaillant was first made associate, and then pensionary. In the course of his researches, he had twelve times visited Italy, and twice England and Holland. He was successively married to two sisters; having obtained a dispensation from the pope, upon condition of working for some time as a common labourer at St. Peter's church in Rome. He died on the 23d of October 1706, in the seventy-fifth year of his age.

Vaillant possessed great knowledge and skill as an antiquary, and published various works, of which the following are the most important. Numismata Imperatorum Romanorum præstantiora, a Julio Cæsare ad Posthumum et Tyrannos. Paris. 1674, 4to. Paris. 1694, 2 tom. 4to. Romæ, 1743, 3 tom. 4to. This last edition contains additions and improvements by Baldini; and a supplement was published under the title of Jos. Khell ad Numismata Imperatorum Romanorum a Vaillantio edita Supplementum. Viennæ, 1757, 4to. Seleucidarum Imperium: sive, Historia Regum Syriæ, ad fidem Numismatum accommodata. Paris. 1681, 4to. Hag. Com. 1732, fol. Numismata Ærea Imperatorum, Augustorum, et Cæsarum, in Coloniis, Municipiis, et Urbibus jure Latino donatis, ex omni modulo percussa. Paris. 1688, fol. Numismata Imperatorum, Augustorum, et Cæsarum, a Populis Romanæ ditionis Græce loquentibus ex omni modulo percussa. Paris. 1695, 4to. Amst. 1700, fol. Historia Ptolemæorum Ægypti Regum, ad fidem Numismatum accommodata. Amst. 1701, fol. Nummi Antiqui Familiarum Romanarum, perpetuis interpretationibus illustrati. Amst. 1703, 2 part. fol. Arsacidarum Imperium: sive, Regum Parthorum Historia, ad fidem Numismatum accommodata. Achæmenidarum Imperium: sive, Regum Ponti, Bosphori, et Bithyniæ Historia, ad fidem Numismatum accommodata. Paris. 1725, 2 tom. 4to. This posthumous work was published by Charles de Valois, of the Académie des Inscriptions.

VAIR, or Vaire, a kind of fur, formerly used for lining the garments of great men. It is represented in engraving by the figures of little bells reversed, ranged in a line.

VAIRY, in *Heraldry*, expresses a coat, or the bearings of a coat, when charged or chequered with vairs.

VALAISE, or Wallis, a canton of Switzerland, in the south-western part, a district comprehending a large portion of the Alps and the land between them and Italy. It extends in north latitude from 45° 55′ to 46° 30′, and in east longitude from 6° 35′ to 8° 9′, containing 1254 square geographical miles. It is bounded on the north-west by the Lake of Geneva and the canton of Vaud, on the north by Berne, on the north-east by Uri and Tecino, on the east, south-east, and south-west by the states of the king of Sardinia.

This canton is on every side surrounded by lofty mountains, so close to each other that the passes between them are few and very narrow. These ranges on the boundaries present some of the loftiest pinnacles of the Alps, such as Monte Rosa 14,580 feet in height, the Matterhorn or Cervin 13,380 feet, St. Bernard's 10,380 feet, the Grimsel 8580 feet, the Col de Baume 7080 feet, and the Simplon 6174 feet. The most practicable passes through these ranges, which, however, are often dangerous in winter, though kept open at a vast expense, are that by the Gemmi, the Grimsel, the Furca, and the Antonierberg, to the interior of Switzerland; that by the St. Bernard and the Simplon into Italy; and that by St. Maurice into the canton of Vaud. In the interior there are lower ranges of Alps, generally running from north to south, and thus dividing the whole surface into small vales. These vales differ much in their character; some of them are stoney and marshy, and others sterile, but others of them have valuable meadows, and land, which, when cultivated, yields profitable crops.

The climate is excessively variable. The lofty Alps protect the canton from the north wind, but the raw east wind brings frost and snow. The west wind brings heat, and the sudden changes are prejudicial to health. To these sudden and violent changes are attributed the fevers which are so prevalent; and in part is attributed to them, though in part to the Tuffa water, the great number of cretins that are to be found in the canton.

The chief products of the country are cattle, and the butter and cheese which they yield. Much of the cheese is made from the milk of goats, which are much more numerous than sheep. Horses are but rarely seen except on the great road; but many mules are used for riding as well as for purposes of husbandry. The corn grown is principally barley and oats. In some of the southern valleys wine is made to a considerable extent. The growth of various fruits gives much occupation to the inhabitants. In many districts chesnuts are used as a substitute for bread. There is abundance of wood in the forests, but it is chiefly used at home for fuel or building. There are no manufactures except those of the domestic kind, which each family must manage for itself as well as it can.

The only export articles are wine, cattle, cheese, hides, wool, and dried fruits, which are sold to purchase salt, corn, iron, colonial goods, and clothing for the very few who can afford better dresses than their neighbours. In fact the commonest gratifications which in other countries have become almost necessaries, must be dispensed with, as the mass of the people are too poor to purchase any thing, and therefore must rest satisfied with what their own hands, with native materials, can provide.

The population of the canton in 1838 amounted to 75,798 persons, of whom 25,000 were of German origin, 46,000 of French, and 4750 of Italian, all speaking corrupt dialects of the several races from which they are derived. They are of the Catholic church, and no other public worship is permitted to be exercised. The ecclesiastical divisions are forty-eight parishes, and there are eight monasteries or nunneries. The bishop of Sitten, or Sion, is the head of the church under the pope.

The constitution is a pure democracy. Each male that has completed his eighteenth year has a vote; when he has completed his twenty-first may be chosen a representative, and after his twenty-fifth may become one of the executive council. The legislature assembles twice in the year, but a committee of it is permanent, and assists the landamman or governor. All the public officers are appointed for two years. Every man is enrolled in the militia. The canton is bound to furnish a contingent of 1280 men to the general confederation, and to pay a contribution to the same of 9600 francs. The whole revenue is 133,100 francs, and the annual expenditure 114,820 francs. The capital is Sitten, a small city, with 2500 inhabitants, on the Simplon road.

VALANGIN, a market town, the capital of a county of the same name in the canton of Neufchâtel, in Switzerland. It stands on a narrow pass between mountains, on the river Seyon. It is the seat of a court of justice over a large district, with three towns in it, and it contains 5640 inhabitants. Near to it is a very large cotton manufactory. Lat. 47. 0. 42. Long. 6. 48. E.

VALCKENAER, Lewis Caspar, one of the ablest scholars of the eighteenth century, was born at Leeuwarden in Friesland, in the year 1715. He prosecuted his academical studies at Franeker and Leyden, and at an early age distinguished himself by his uncommon skill in ancient literature. The first appointment which his learning procured him was that of conrector of the gymnasium of Campen; and in 1741, after he had recommended himself by some very erudite publications, he succeeded Hemsterhusius in the Greek chair at Franeker. With this, in 1755, was united the professorship of Greek antiquities. In 1766 he was called to the university of Leyden; where, with the chair of the Greek language and Greek antiquities, he also held that of the history of his native country. In this honourable station he continued for nearly twenty years, in the enjoyment of a very high and well-earned reputation. He formed many excellent scholars, and eminently contribu d to maintain the credit which the university had acqu d as the first seminary of Greek literature. He died on e 15th of March 1785, in the seventieth year of his age.

lckenaer possessed a masterly acquaintance with the ent e compass of the Greek language and literature. He wa an acute and sagacious critic, and he displayed no me talents as a Latin orator. We subjoin a list of his pri ipal works. De Ritibus in Jurando a veteribus Hebra maxime ac Græcis observatis. Franequeræ, 1735, 4to Specimina Academica. Fran. 1737, 4to. Ammoniu de adfinium Vocabulorum Differentia. Accedunt Op seula nondum edita, &c. Lugd. Bat. 1739, 4to. Eurip is Phœnissæ. Interpretationem addidit H. Grotii; Gr a castigavit e Mstis, atque adnotationibus instruxit; sch ia, partim nunc primum evulgata, subjecit. Fran. 1755, 4to Euripidis Hippolytus, &c. Accedit Diatribe in Eurip s perditorum Dramatum Reliquias. Lugd. Bat. 1768, 4to. The Diatribe, which is very able and elaborate, was pu shed separately in 1767. Theocriti, Bionis, et Moschi Ca ina Bucolica, Græce et Latine. Emendavit variisque lec nibus instruxit. Lugd. Bat. 1779, 8vo. He had published ten idyls of Theocritus in 1773. Ti. Hemsterhusii Or ones, quarum prima est de Paulo Apostolo. L. C. Va kenari tres Orationes, quibus subjectum est Schediasma, Spe men exhibens Adnotationum Criticarum in Loca quædam Librorum Sacrorum Novi Fœderis. Præfiguntur duæ Or ones Joannis Chrysostomi in Laudem Pauli Apostoli, cu veteri versione Latina Aniani, ex. cod. MS. hic illic em data. Lugd. Bat. 1784, 8vo. Schedius was the editor his Observationes Academicæ, quibus via munitur ad Ori nes Græcas investigandas, Lexicorumque Defectus res iendos. Traj. ad Rhen. 1790, 8vo. These observatio are accompanied with the prelections of Van Lennep De nalogia Linguæ Græcæ. The following posthumous wo of Valckenaer was published by his son-in-law Luzac: Cal naehi Elegiarum Fragmenta, cum Elegia Catulii Callim hea. Lugd. Bat. 1799, 8vo. J. A. H. Tittmann publish Davidis Ruhnkenii, L. C. Valckenarii, et aliorum, ad Joh Aug. Ernesti Epistolæ. Accedunt D. Ruhnkenii Obser iones in Callimachum, et L. C. Valckenarii Adnotation ad Thomam Magistrum. Lipsiæ, 1802, 2 tom. 8vo. Dia be de Aristobulo Judæo, Philosopho Peripatetico Ale ndrino. Lugd. Bat. 1806, 4to. Opuscula Philologica Critica, et Oratoria, nunc primum conjunctim edita. Lip e, 1809, 2 tom. 8vo.

H son John Valckenaer, successively professor of law at I neker, Utrecht, and Leyden, was likewise known as an a hor. He was a strenuous adherent of the popular part in opposition to the house of Orange; and he acted a c spicuous part in the public affairs of the eventful era to w ch he belonged. He became a member of the legislati body of the new republic; and the Batavian directory sent im on a diplomatic mission to Spain. When Bonapart had divulged his intention of incorporating the kingdom f Holland with the French empire, Valckenaer was desp ched to Paris in order to remonstrate against such a mea re. His eloquence was however ineffectual; and, on his urn, relinquishing all connection with politics, he took imself to a delightful retreat in the vicinity of Haarlem, here he died on the 19th of January 1820, at the age of si y-two.

V LDENSES, WALDENSES, VALLENSES, VALDESII, VA ES, or VAUDOIS, a community of Christians in the Cott n Alps, well known under these names, whether used as a rritorial or ecclesiastical distinction. They formerly peop d a continuous and extensive mountain tract of cou y both in France and Italy, in the provinces of Dauphiné and Provence, and in Piedmont, when these provinces were under one sovereignty; but, reduced by a long series of persecutions, they are now confined to the three valleys of Perosa, San Martino, and Lucerna, on the Italian side of the mountains, in the dominions of the king of Sardinia.

Valdenses.

In these beautiful valleys, extending up the slopes of mount Viso and mount Genevre, and lying between the rivers Pelice and Clusone, which come to a point of junction a little before they fall into the Po, the remnant of the Valdenses still have their existence as an established church of regular organization. They have endowments of land, churches, schools, and institutions peculiar to themselves; they have a liturgy of their own; they are recognised by the laws of the country to which they belong, and protected by treaties and compacts with the Protestant powers of Europe. It has not been accurately determined at what time, or how, they obtained the appellation of Valdenses, under which they have been known since the 12th century, and which, from the resemblance in sound and orthography, has been erroneously thought to identify their derivation with that of the disciples of Valdo, the Lyonese reformer. From the circumstances of the times, and, from the fact, that the fugitives from Lyon took refuge[1] with them as with a people of similar religious tenets, they come into historical notoriety under the name of Vaudois and Waldenses contemporaneously with Valdo; but traces of them, as a body of subalpine Christians, protesting against the errors of Rome, are found in ecclesiastical records of a much earlier date.

The traditional antiquity of the Valdenses.

That the Cottian Alps have been inhabited by a relatively pure association of Christians from time immemorial, who have testified for the truth, upon the same articles of faith, as the Protestant churches of modern times, is a tradition not unsupported by documentary evidence, but still open to discussion. The Valdenses of these regions maintain that they are descended from a race, who peopled the same villages, and professed the same gospel, in the first centuries of the Christian era. "We have inherited our religion," say they, "with our lands, from the primitive Christians." This is no modern pretension, put forth since the Reformation; for the same language, as to their antiquity, was held by their ancestors, not only after the time of Valdo, but in the age before that reformer, to whom their origin is sometimes imputed.

The author of the "Nobla Leyczon,"[2] A.D. 1100; Moneta,[3] who wrote against the alleged heresies of his day, and died in 1240; and Reinerus,[4] the inquisitor, whose treatise was completed in 1250; all bear witness that the religionists mentioned by them, under the appellations of *Vaudès* and *Lombardi Pauperes*, and whom we are led to identify with the Valdenses, professed, in those times, to trace their religious genealogy and characteristics to the primitive ages.

Tenets of the Valdenses.

The inquirer, who would make himself master of the religious character of the Valdensian church, must take care not to be led out of his way in search of it. He must confine his attention to one particular locality, that is, the subalpine territory lying between Mount Genevre and Mount Viso. It has been the mistake of many writers and readers to ask among the heretics of all times and places for the creed of the Valdenses. But, if we would do them justice, and ascertain the articles of faith really maintained by them, we should look to three periods of time for this information.

The *first* is the present period.

The *second* is a point of time immediately before the Reformation.

[4] inerus de Sectis Antiquorum Hæreticorum, c. 4. Bib. Patr. vol. iv.

The *third* is the age immediatialy before that of Valdo. The authorities to be consulted for the religious opinions of the Valdenses at these periods, are, 1. the public acts of synod, and the liturgy of the Valdensian church, as it now exists; 2. the account given of the Valdenses by Claude Seyssel, archbishop of Turin, after his visitation of the diocese in 1517; and, 3. that admirable monument of faith, hope, and charity, called the *Nobla Leyczon*, alleged to have been written in the year 1100. These represent the Valdenses as rejecting image worship, the invocation of saints, the necessity of auricular confession, the obligations to celibacy, papal supremacy and infallibility, and the doctrine of purgatory; as professing to take scripture for the only rule of faith; and believing in the holy Trinity, in original sin, in the atonement and mediation of Christ alone, in justification by faith, in the two sacraments of baptism and the Lord's Supper, and in the apostolical ordinance of holy orders.

History of the Valdenses.

The misrepresentations of friends and enemies, and the destruction of their documents in the course of numberless persecutions, render it a hard task to disentangle Valdensian history from the confusion under which it lies. Notwithstanding all that has been written on the subject, we still want evidence of a more convincing and irresistible nature, as to their origin,[1] succession, and progress. There are provoking uncertainties attending the inquiry; but amidst all the clouds in which it is involved, one bright truth gleams strongly out of the darkness, even from the time when the Valdenses came first into notoriety and conflict. The 'little Christian flock has been indestructible, in defiance of those who strove to be its destroyers, and, like the flaming bush, it has burned, but has not been consumed. Neither executions nor arguments, neither violence nor calumnies, have prevailed for its extinction. To what can this be attributed? Not to the protection of situation only, not to accidental causes, but, under the divine blessing, to the stronghold which the sanctity of truth has upon the sympathies of men, in spite of their angry passions. The Valdenses found favour with their sovereigns, and obtained immunities, privileges, and pledges of security from time to time, which could not have been forced from the strong by the weak, and never would have been conceded to fanatical or rebellious subjects. The very fact of their existence is an attestation to the purity of their faith and conduct, and a refutation of those who reproached them with gross errors. He who has made darkness his secret place, has mysteriously preserved them; and astonished the pride of Christian orthodoxy, by making a fold for these few sheep in the wilderness, from whence they might rebuke error, and bear witness to the truth.

The history of Piedmont, and of all the states subject to the house of Savoy, whether in the Cottian Alps, or elsewhere, has hitherto been a sealed book, in consequence of the reluctance of the dukes of Savoy and kings of Sardinia, to permit the family and state documents to be brought to light. Muratori confessed that he despaired of illustrating the history of Piedmont.[2] Giannone relinquished in disgust his intended history of the country, because the archives of Turin were not more freely opened to him. Hallam[3] says that the history of Piedmont is far less elucidated by ancient and modern writers than that of any other part of Italy; and Dal Pozzo, a native writer, has declared,[4] in a very learned work, that in no region of Europe has the truth of history been so concealed.

Another circumstance which has contributed to darken Valdensian history, is the doubtful line of separation between kingdom and kingdom, diocese and diocese, during the middle ages, and the frequent transfers from one authority to another. The bishops of Turin and Embrun sometimes exercised jurisdiction almost indiscriminately on each side of the Cottian Alps; and in many of the old documents, when we read of the valleys of Fraissiniere, Pragela, Clusone, and others, it is difficult to understand to what localities or people they refer. Need it therefore occasion surprise, if many links are found to be wanting, in the chain of documentary evidence necessary to unite the present with the past, in the annals of an obscure district, belonging to a realm whose entire history is wrapt in mystery?

In a few years, perhaps, it will be more easy to give a satisfactory account of the Valdenses, because the present king of Sardinia is permitting the ancient records of his states to be examined and published; and an historical commission at Turin, has already sent many important documents to press, which throw light on subalpine affairs.[5]

It is in vain to pretend to reduce the annals of the Valdensian church to any thing like connected history, till we descend to the period when persecution brought it into notice. We may, it is true, pick up a few materials relating to the country, and to the general aspect of religion, from the early documents which have come down to us, but these are scanty and unsatisfactory. For example, we learn that the Cottian Alps received the gospel in the second century, and that Irenæus, bishop of Lyon, made himself master of the Celtic language, that he might minister among the mountaineers; that facilities of intercourse between the subalpines and the inhabitants of the plain, were secured by good roads leading through the centre of the valleys now called Protestant, in the direction of Mount Genevre, Oulx and Fenestrelle that the village of St Secondo, in the valley of the Clusone is so called from a martyr of that name in the year 120 that Crisolo, near Rora in Val Lucerna, was the place o St Geoffrey's concealment, before his martyrdom in 297 and that, during the persecution of Diocletian, many Christians of the Theban legion found refuge in these regions.[6] We know that a hundred years afterwards, Ambrose o Milan, whose diocese extended to the Alps, complained o his mountain clergy refusing to become celibates, on th plea of ancient custom;[7] and that Vigilantius made th Cottian Alps the place of his sojournment,[8] when he op posed himself to the errors of the church; because ther he was received with kindness by professors of Christi anity, who refused to adopt the observances of *Monachism* prayers for the dead, saint and relic worship, and othe superstitions, which were creeping into practice.[9] Agai after an interval of more than 400 years, we find, that do trines, called by Jonas of Orleans and Dungalus,[10] *th heresy of Vigilantius*, were still cherished here, and tha Claude, bishop of Turin, "that bright and golden ring i the chain of Cisalpine Protestantism," gave the sanction his episcopal authority to opinions, which the Gallic r former of the fourth century had been reviled by Jero r propounding. Claude found two parties in his diocese, ne of which favoured his schemes of church reform; and ter his death (according to the authority of Dungalus) was called the sect of Claude. Thus it is certain that Vi-lantius, and after him Claude, left disciples in these parts,[1] st where we are looking for them; but we have no ground r maintaining that the Valdenses were in a state of seces-on from the provincial bishops of France or Italy, within hose dioceses they were situated, at either of the periods which we have just referred, the fourth and the ninth enturies. In those days, and for two or three hundred ears after Claude, the truth might be held, and public tes-monies for the truth might be given, and protests against e errors of Rome might be made, without the necessity f separation from the church called catholic: witness the reat Iconoclastic question which agitated Christendom in e ninth and tenth centuries. There is reason therefore believe that, until a much later period, congregations of e Cottian Alps may have continued to maintain a purer ith than that of Rome, without leading to any proceedings those parts, which could be called acts of schism on the ne side, or of persecution on the other.

---

[1] On the origin of the Valdenses, some curious materials for conjecture will be found in the history of the Gothic Christians of the fif century, and their relics in France and Italy. Salvianus de Gub. Dei, l. 7, Alcuin in his Epistles, and Theodolphus, three hundr years later, speak of the purity of their lives, while they allude to the imperfections of their notions in relation to church observances.

The accusing and remonstrating voice within the church, nd not open secession from her, may have distinguished he Valdensian from the Romanist, for a series of ages; nd the political condition, as well as the natural position f the territory, to which he belonged, may have proved is security. There was no occasion for him to separate, o long as he was not compelled to do violence to his con-cience; so long as the civil rights enjoyed in Ostro-gothic nd feudal Italy protected him.[2] In some parts of the south f France, as well as in the Cottian Alps, opinions were eld at variance with those of the great body of the church, ithout bringing the dissidents into violent collision with t. There the Gothic Christians, to whom Alcuin addressed n epistle of expostulation,[3] professed their disbelief in he virtue of auricular confession and sacramental absolu-ion, and remained unmolested; and there the Christians f Narbonne, in 820, (if we interpret rightly the metrical[4] lescription of Theodulphus, bishop of Orleans,) had an cclesiastical system of their own, which savoured of reli-gious principles very different from those held at Rome, without being denounced as schismatics. Until the bishop f Turin, acting upon the system introduced by Innocent he Third, obtained the authority of the Emperor Otho in 1210, to persecute the Valdenses, we have no instance of ny public act of oppression committed in the Piedmontese valleys of the Alps against religious freedom. Up to that time the strongholds of nature, and the protection of the Lombard law,[5] which, in its code of personal legislation, permitted every man to choose the national law under which he would be governed, gave the people in these Alpine fastnesses, privileges of which even pontifical tyranny could not deprive them, and offered a permanent settlement to the assertors of primitive Christianity, who, while they protested against superstitious novelties, communicated with the established clergy, as Wesleyan Methodists now profess to do, and vindicated their claim to be considered members of the church of Christ. The mass of historical documents which the commission at Turin has published since 1836,[6] exhibits too many marks of suppression not to excite our fears that much information relating to the "Evangelical Valleys of Piemont" has been withheld. Enough has however been brought to light, to satisfy us, that the political condition of the Cottian Alps, and of the people whom some ecclesiastical writers are fond of deriding under the term "brutæ gentes Alpium," (between the age of Claude and the first public persecution of the Valdenses) was exactly such as to secure religious objectors from molestation, and to justify the language, which the Valdenses have invariably held in all their petitions to their sovereigns, when their religious liberties have been threatened—"We have asserted our right to enjoy liberty of conscience," "da ogni tempo," "da tempo immemoriale," from time immemorial. "Is it not extraordinary," says the historian Leger, "that it has never once happened that any one of our princes or their ministers should have offered the least contradiction to their Valdensian subjects, who have again and again asserted in their presence, 'We are descended from those who, from father to son, have preserved entire the apostolical faith, in the valleys which we now occupy. Permit us therefore to have that free exercise of our religion, which we have enjoyed from time out of mind, before the dukes of Savoy became princes of Piemont?'"

The supreme authority of the princes of the house of Savoy was not fully established in Piedmont until the middle of the thirteenth century, (before that time the emperors of Germany exercised all the rights of suzeraineté) and it is a curious fact, that the house of Savoy arrived at absolute power by means of the public confidence which it enjoyed, in consequence of its equitable government, and faithful adherence, for many ages, to compacts made with its subjects. These compacts were the origin and the preservatives of the religious liberties of the Valdenses. "We are obliged to tolerate heresy in the valleys of our realm," was the confession of a duke of Savoy in 1602.[7] It was a matter of solemn stipulation, recorded in the ancient charters and documents now under publication at Turin, that the inhabitants of certain townships, communes, and villages, should remain in the undisturbed possession of their accustomed rights and franchises; and some of the very communes and hamlets which are now the dwelling places of the Valdenses, are named among those entitled to such privileges.

In allusion to these immunities of the Valdenses, based on *Charter*,[8] Archbishop Seyssel made the following bitter complaint: "It has contributed not a little to the toleration of their heresy, that it has never wanted persons to protect and favour it, and among those especially who ought to be the guardians of the Christian religion, inasmuch as they rule and reign over provinces and kingdoms."[9]

We have no well-authenticated record which will enable us to say, when the feeble tie was broken, which still kept the Valdenses in communion with the provincial bishops of Turin and Embrun, while they protested against Romish corruptions. Sclopis, a Piedmontese writer on jurisprudence, of great celebrity, who has made it his business to search into the history of the laws and customs of his country, declares that he cannot assign any period to the first appearance of schism in the subalpine valleys, nor can he discover the origin of the name *Valdenses*.[10]

It is probable, however, that being excommunicated at the beginning of the thirteenth century, after their reception of the followers of Valdo, they were then obliged for the first time to constitute ministers of their own, out of the clergy, whose orders were derived from the national churches of France and Italy, and who espoused their cause. That they had originally the form of an episcopal church, with clergy of different orders, (although their discipline is now Presbyterian, very much resembling that of the Church of Scotland,)[1] appears both in an ancient MS. which speaks of *regidors*,[2] or *leaders* of the flock, as well as of priests; and in the direct and plain evidence of Claude Seyssel in 1520, who speaks tauntingly of persons whom they called their *bishops* and *priests*, and challenges them to show from what lawful source of authority, from what church, and from what province, they, who boasted of their apostolical descent, derived their orders and succession.[3]

---

[1] It is curious to observe, how, from Philastrius, who died in 387, down to Ratherius, who died in 974, and again, from Peter of Clugny, who wrote in 1127, to the Reformation, *mountain districts* are stated to have been the *latibula*, or places of security, where nonconformity with the dominant church lurked.

[2] These immunities were of a very ancient date. See the privileges granted to Gothic and other unorthodox soldiers by Justinian, 523, xii. Cod. de Hær.

[3] Alcuini Epistola 26, aliter 71, ad Gothos.

[4] See Theodulphi Parænesis ad Judices.

[5] See Guizot's Lectures on European Civilization, lecture 3. In Germany as well as in Lombardy there was a succession of Christian congregations, with more or less of othodoxy, who must have been connected with the sectarians of whom Evervinus complained to St Bernard in 1140. "We and our fathers," said they, "are apostolical in our doctrine and life."

The fiercest declaimers against Valdensian schismatics might find some extenuation for a people who were forced into secession; first, by the corruptions and spiritual neglect of the clergy of the dominant church; and, secondly, by excommunication. Every ecclesiastical history makes mention of the utter depravity of most of the Romish clergy of the tenth, eleventh, twelfth, and thirteenth centuries; and we gather from the first volume of the Piedmontese Historical Documents, published in 1836, that at one time nearly all the ecclesiastics of the Cottian Alps fled from before the Saracen invaders, and never returned to their parishes; and at another time that there was a wreck of churches (*naufragatis ecclesiis,*) and destitution of pastors throughout the whole diocese of Turin. Endowments for parochial service were transferred to monasteries at a distance, and villages were left without regular pastoral superintendence. One charter states that a third of the whole mountain territory between Mount Cenis and Mount Genèvre was made over to a distant convent. Another consigns no less than half of all the lands lying between Pignerol and Col Sestrières to an abbey at Pignerol. A third despoils the whole of Val Guichard of its rents, for the enrichment of a fraternity of monks in another part of the country, in the plains on the banks of the Po. All this must have contributed to produce that state of spiritual destitution which ultimately led to, and warranted separation; and when the severance was once completed, the hierarchy of Rome could never re-establish its authority over those valleys of Piedmont which are now called Protestant. They were so free from Romish intrusiveness at one period, that Vincentius Ferrerius, the Dominican, who preached to the Valdenses in the year 1405,[4] reported to the principal of his order, that they had not heard the voice of a minister of the church for thirty years before; and Claude Seyssel declared a century afterwards, that so entirely had they been abandoned by priests and bishops, no prelate but himself had dared to approach them within the memory of man.

The transfer of property in the valleys, to monasteries and convents, was the first step that led to persecution. The possession of lands in signoralty carried with it certain rights of jurisdiction, which enabled the monastic bodies to exercise temporal as well as spiritual tyranny. They acquired the power of holding local courts for the adjudication of all criminal causes, co-extensive with that which had been originally conferred on the feudal proprietors for the protection of the people of their domains; so that the very privileges which were favourable to religious liberty, while they were exercised by lay superiors, became dangerous to the vassals of estates, in process of time, when they were made over to ecclesiastics. The commencement of the thirteenth century is the era from which we date those horrible atrocities with which religion has been insulted, and humanity outraged, to appease the offended majesty of Rome. Innocent the Third, and Dominic, the father of the Inquisition, (the seraphic spirit of Dante's commendation) divide the honour of having let loose fire and sword against those who presumed to question the dogmas of the Vatican, in two new forms, impiously called "missions of peace and good will." The one was the crusade against the Albigenses, which swept multitudes from the face of the earth in open warfare; and the other was the institution of a secret tribunal, which had its informers and its executioners every where, and, as an "act of faith," condemned thousands, after the mockery of a trial, to expire in the flames, or to linger out life in a dungeon. But though some martyrs were dragged to the stake from the vicinities of the Cottian Alps, nearest to the plains of Piedmont on the one side, and to the cities of Dauphiné on the other, yet the more secluded of these regions continued to be secure asylums until the end of the fourteenth century. The communes of Fressinière and Argentière, in the diocese of Embrun, on the French side of the mountains, were then ransacked for victims, in obedience to a papal bull.[5] Whole families were sacrificed, and others were obliged to fly to the very edge of the glaciers for safety. But it is remarkable, that although a similar bull was issued against the nonconformists of the valleys of Lucerna and San Martino on the Italian border, no means were there found of putting the exterminating commission in execution. Again and again the temporal sovereigns of the Piedmontese Valdenses received mandates from Rome to draw the sword against them, and to "crush the serpent," but they would not. Even when the persecuting storm of 1400 extended from Dauphiné to the Italian valley of Pragela, which was then under the dominion of France, the adjoining valleys of Lucerna and San Martino heard the pontifical thunder, but were unscorched by its lightning.

At length the memorable bull[6] of Innocent the Eighth, which gave unlimited powers to Albert de Capitaneis to carry confiscation and death throughout the whole of those parts of the sees of Embrun and Turin which were infected with heresy, precipitated a host of armed enemies upon the mountain retreats of the Valdenses. The edict of Iolanta, the regent-mother, during the minority of the duke of Savoy, in the year 1476,[7] in which she called on the authorities of the province of Pignerol to assist the inquisitors in compelling heretics, and especially those of Val Lucerna, to come into the bosom of the church, is one of the first state papers which indicate a departure from the mild and tolerant principles on which the house of Savoy had hitherto acted. But the sanguinary torrent rolled through these valleys, without forcing any of the inhabitants into the arms of Rome. Some subsequent edicts of the dukes of Savoy, speak of their Valdensian subjects, not under the obnoxious appellation of heretics, but under the gentle and more courteous term of **Religionists**, and call them "men of the valleys," "beloved and faithful vassals," whom t y recognised as privileged persons, entitled to immuni-t s and franchises, by virtue of ancient stipulations.[1]

---

[1] In the middle of the sixteenth century several changes were effected in the government of the Valdensian church. The principal authority rests with ecclesiastical officers called the Table, consisting of the moderator, the moderator-adjoint, and the secretary, assisted by two lay members. These are elected by the Synod, which is held every five years, in the presence of a royal commissioner. The moderator presides at ordinations. Pastors are nominated by parishes, subject to the approbation of the Table, and confirmation of Synod.

[8] Those of 1499 and 1509

State policy, disputes with France, and the necessity of c ciliating the borderers, when a band of gallant soldiers w s required for the defence of the frontier, often operated i their favour, in the moment of danger; and even at ti es when the sovereigns of the principality consented to t ir destruction, the lords of the soil became their advo-c es. Thus, in the year 1553, when the havoc which was n de among the nonconformists of Provence and Dau-p né, reached the valleys of Piedmont, it would have been n re fatal, had not Blanche, countess of Lucerna,[2] inter-p ed in behalf of her dependents.

n 1560, the dark cloud which had long been gathering o r the mountain church, burst upon it with all its fury; a never did the majesty of truth and innocence stand out n re brightly to view, than during the tempests of perse-c ion, which raged at intervals for the next hundred years a more.

The subalpine communities, which had been placed un-d papal interdicts, saw themselves exposed to the hostile p ver of the French king on one side, and to that of the d e of Savoy on the other. They were commanded by e cts to banish their ministers and schoolmasters, to ab-s n from the exercise of their own forms of worship, and t attend the services of the Romish church. They re-f ed, and orders for confiscation, imprisonment, and death, v e launched against them. Hundreds perished on the s ffold, or at the stake; and the villages swarmed with l gands, who, under the name of officers of justice, plun-d ed the wretched inhabitants, and haled them to prison, u il the dungeons were choked with victims.

The population of the valleys still remaining faithful to t religion of their forefathers, the sword was openly un-s athed, and the scabbard thrown away. An armed force, c nmanded by a chief whose name was in terrible con-t st with his character, the Count de la Trinité, poured i the proscribed territory. But a spirit stronger than t sword upheld the Valdenses, and an arm more powerful t n that which assailed them, fought on their side. The v ages near the plains were deserted, the women, the chil-c n, the feeble, and the aged, were sent for refuge to the l ghts of the mountains, to the rocks and to the forests. l ery man and boy who could handle a weapon, planted l nself against the invaders, and a successful guerilla war-f e was carried on by small brigades of peasants, against t veteran troops who were let loose upon them. Greater e ploits, and instances of more enduring fortitude, were n ver recounted, than those which have immortalized the r istance offered by the Valdenses to their oppressors. It n st however suffice to say, that the history of the Val-c nses, from the year 1560 to the close of the eighteenth c ntury, is a narrative of sanguinary struggles for existence, w h very few intervals of repose.

If the churches of the valleys had an intermission of suf-f ing under one reign, they were driven to desperation in a other. The years 1565, 1573, 1581, 1583, and the pe-r d between 1591 and 1594, are memorable as dates of re-l ious and civil conflict.

In 1595, the duke of Savoy smiled upon his Protestant s jects; in 1596 and 1597 he persecuted them. From 2 to 1620, a series of edicts,[3] some threatening, and o ers indulgent, kept the Valdenses in a state of perpetual s pense and agitation; but the tenor of the most alarming o these, which confined them within certain limits, proves t t they had rights and privileges, within those limits at least, which nothing but the importunity and the misrepre-sentations of the Romish hierarchy, could induce their sove-reigns reluctantly to violate.

Of the twenty years that followed, almost all were distin-guished by some act of cruelty or oppression. In 1640,[4] the appointment of an English envoy at the court of Turin, and his occasional residence at La Tour, the principal village of the Valdenses, shed a ray of transient sunshine over this afflicted people; but this was shortly followed by a hurricane of persecution similar to that of 1560, and unutterable atro-cities were committed by the soldiery employed to enforce the destroying edict of 1655. That year would have seen the last of the Valdenses, had not all the Protestant powers of Europe interposed, especially England, whose supreme ruler, Oliver Cromwell, under the influence of Milton, be-came their protector.

In 1686, Victor Amadeus, the young duke of Savoy, in-stigated by the courts of France and Rome, and ambitious of succeeding where his ancestors had failed, sent an over-whelming body of troops into the valleys of Lucerna, Pe-rosa, and San Martino, to compel the inhabitants to go to mass. During three years and a half, the exercise of the ancient religion of the Valdenses had to all appearance ceased in Piedmont. Those who would not conform were obliged to flee for their lives. But the return of eight hun-dred Valdensian exiles in 1689,[5] who marched from the borders of the lake of Geneva to their native mountains, for the recovery of their rights, was signalised by incidents un surpassed in the history of providential and romantic events, and was crowned with success. At this critical juncture, a quarrel arose between the king of France and Victor Ama-deus, which induced the latter to take this heroic band and the scattered remnant of his Protestant subjects into fa-vour. "Hitherto," said he, "we have been enemies, but from henceforth we must be friends; others are to blame more than myself for the evils you have suffered." This happy turn in their affairs was followed by treaties between the English and Piedmontese governments, in the reigns of William the Third and Queen Anne, articles of which were meant to secure to the Valdenses the undisturbed exercise of their religion within certain territorial limits.[6] From that period to the present, Great Britain has been empowered, by virtue of solemn compacts, to interpose for their pro-tection, and their churches ought to have had rest.

But the wrongs of the Valdenses were not yet at an end, and their sovereigns, under their new title of kings of Sar-dinia, forgot to be generous and just. Again and again these sufferers have had to contend not only against petty injuries and harassing grievances, but also against absolute oppression. By an act of open violence, the valley of Pra-gela was dragooned into conformity with Rome, in the year 1727, on the diplomatic pretence, that this region was not included in the articles of treaty which secured toleration within defined boundaries. The English ambassador at Turin remonstrated, and urged the sacred engagements which guaranteed toleration and safety to the Protestants of Piedmont, but he was not properly supported by his go-vernment at home, and the objects of his sympathy cried for redress in vain.[7]

During the French empire of Napoleon, when the iron crown of Italy was placed on the head of the Corsican, the Valdenses enjoyed equal rights and privileges in common with the rest of their countrymen. But, at the restoration of the house of Savoy to the kingdom of Sardinia, four days after the king had taken possession of his palace at Turin, they were replaced under their former disabilities, and bare

toleration only was conceded to them.[1] The restored prince acknowledged, on more occasions than one, "the constant and distinguished proof which the Valdenses had ever given to his predecessors of attachment and fidelity;" and bore this testimony to their merit: "I know I have faithful subjects in the Vaudois; they will never dishonour their character." But still he listened to evil counsel, and the yoke was again placed upon their necks. And evil counsellors still prevail. In 1832, the measures adopted against the Valdenses were so threatening, that the British parliament took up their cause; and extracts of the treaties between Great Britain and the dukes of Savoy and kings of Sardinia, were ordered by the House of Commons to be printed, on the motion of Sir R. Inglis, with the correspondence of the British minister at Turin, relative to the treatment of the Protestants in Piedmont in 1727.[2]

The reigning king of Sardinia, Charles Albert, is disposed to shew them kindness, and to place them on a level with his other subjects. He has proved this by numberless acts of favour; but the tiara and the mitre are too strong for the crown in Piedmont; and the baneful influence of the papal authority, so late as September 1837, wrung from the reluctant king two articles in the new code of Sardinia, by which the intolerant edicts of the 16th and 17th centuries[3] are renewed, and may be put in force as soon as the Roman hierarchy shall feel itself strong enough to do so. In the meantime, another engine is employed against the hapless Valdenses. The rich order of St Maurice and St Lazarus has contributed 238,617 francs, (L.9544) and an income of 17,000 francs (L.680) a-year, towards the establishment of a fraternity of missionary priests at La Tour, whose business it will be to make proselytes from among the descendants of a race which has never yet swerved from its faith, but which will now be exposed more than ever, to the threats and artifices of an adversary who knows well how to turn opportunities to advantage.

The Protestants of England have not been inattentive to the condition of their brethren in the valleys of Piedmont. Public collections have on several occasions been made throughout the kingdom; and the Society for the Propagation of the Gospel in Foreign Parts is the trustee of considerable funds raised in their behalf. A committee in London, consisting of the archbishop of Canterbury, several bishops, and other persons of distinction, has also been employing contributions in aid of the clergy, hospitals, and schools of the Valdenses, and watching over their interests since the year 1825.

The difficulties with which the Valdenses have now to contend are, poverty, and reduced numbers, being confined to limits which do not produce subsistence for more than a very limited population. They also labour under the disadvantage of having to learn three languages before they can receive competent instruction. Their national language is Italian; their vernacular tongue is a provincial dialect, peculiar to their district; and the language of instruction is French, because in that only they can obtain books of devotion used by Protestants.

If the government of Great Britain should cease to exercise its good offices at the court of Turin, in behalf of the Protestants of Piedmont; or, if the people of Great Britain should become indifferent to the moral and spiritual wants of this impoverished community, the religious liberties of the Valdenses will be no more, and the lamp of this little mountain-church will be extinguished for ever.

Since this article went to press, some additional information on the sacred literature and religious prospects of this interesting community has transpired. Their liberties have been further threatened by three intimations, which strike at the very root of their Christian privileges. The first is an article of the code promulgated at Turin, which forbids the printing of manuscripts, for their use, in other countries, unless they shall have previously passed the censorship at Turin. This will have the effect of cutting off the future supply of religious books and tracts, because the board of censors is composed entirely of Roman Catholics. The second is an order published in the Turin Gazette of 27th December 1840, to this effect:—"By decree of the holy congregation of Rome, the New Testament of our Lord Jesus Christ, translated into the Piedmontese language, is condemned and prohibited." This prohibition, made at the instigation of Rome, appears seven years after the book had passed the censorship, and had been introduced by legal permission into the Protestant valleys of Piedmont. The third is a message sent to the Valdensian moderator, by the president of revision at Turin, demanding by what authority the College of the Holy Trinity at La Tour has a library of books!!

The other intelligence is of a more pleasing nature, viz. the existence of three copies of the ancient Valdensian version of the New Testament. It was feared that all the manuscripts of this valuable and vernacular translation had perished, but some recent inquiries made by the Rev. Dr. Gilly have led to the announcement that three at least remain. In the public library of Grenoble, the Codex No. 488, is a relic of the thirteenth century. It is a manuscript on vellum, a small 4to, containing, in the following order, the four Gospels, the Epistles of St. Paul, St. James, St. Peter, St. John, and St. Jude, the Acts of the Apostles, the Apocalypse, the Proverbs of Solomon, Ecclesiastes, Wisdom, Ecclesiasticus, and the Song of Solomon; all in the Piedmontano-Provençal dialect of the Valdenses.

In the library of Trinity College, Dublin, a transcript of the same version, on parchment, is preserved, which is said to have been written in 1522. In the public library of Zürich, there is also to be seen a copy of an ancient Valdensian translation of the New Testament, which differs in some degree from the two above-mentioned, but is believed to have been written between the years 1350 and 1400. This manuscript is thus described:—"Codex MS. Novi Testamenti Valdensis, C. $\frac{169}{706}$ chartæus, sæculi xiv. formæ 12. nunc constans foliis DIII." (D.F.)

VALDEPENNAS, a town of Spain, in the province of La Mancha and the partido of Ciudad Real, of which partido it is the capital. It is surrounded with walls, is well built, having a college, three churches, nine monasteries and five hospitals, with about 9000 inhabitants. It has some manufactures of gloves and woollen goods, and some tan-n ies, and is celebrated for the wine which bears its name. I taste and colour it resembles the best of the Burgandy w e. In former times, a portion of it was always eng ed for the table of the king; but very little of it finds it way to other countries, from the want of casks to conta it; and from being conveyed in goats' skins it acq res a disagreeable flavour. Good wheat is produced in th neighbourhood. The town is about eighty miles sc th-east from Toledo, and one hundred and ten south of M drid.

---

[1] A very able pamphlet was published in 1829, by Count Ferdinand dal Pozzo, late Maitre des Requetes, and First President of the imperial Court of Genoa, entitled "The complete Emancipation of the Vaudois advocated." In this the author maintains, that by the treaty of Paris, May 31, 1814, the Valdenses were put in possession of all the rights acquired by the inhabitants of Piedmont under the French dominion, and that, in violation of these rights, there are no Protestants now in Europe, in so low and degraded a position as they.

[2] See Orders of the House of Commons, 15th May 1832, and Returns to an Address to his Majesty, dated 24th January 1832.

[3] These, 1st, prohibit the Valdenses from acquiring landed property beyond certain limits, and from exercising certain professions; 2d, forbid them to make proselytes themselves, or to offer any opposition to the conversion of Protestants by Roman Catholics; 3d, prevent their reclaiming their own children, when they have been taken into Roman catholic hospices or convents; 4th, prohibit the augmentation of churches or ministers of religion, even within their own valleys.

VALDO, or **WALDO, PETER**, frequently described as th Lyonese reformer of the twelfth century, appears in contemporary documents under the appellation of *Valdès*. In the earliest existing documents he is called *Valdès* (by W. M pes,) and *Valdesius* (by the Chronicler of Laon), *Valdes*, *Valdius*, *Valdensis*, *Waldius*, and *Waldensis*. Unless he d ived his name from some locality, Valdès or Valdo was h right appellation. The latter is of very common occurre ce in Gallic and Germanic documents, from the ninth t the twelfth century, and *W* is the Germano-Burgundian sp ling. It is uncertain why or where he was first named *P er*. His prænomen *Petrus* occurs, we believe for th first time, in a Latin book of Peter de Polichdorf, w tten during the last half of the fourteenth century.

Contemporary and documentary history is silent as to the p ce and date of Valdo's birth, and the events of his earlier d s; but tradition states that he was born in a place w ch, by some, has been called Vaud, Vaux, Vaudram; by o ers Walden and Val-Grant. There is still a village near L on called Vaux, and another in the mountain region, b ween Mont Dauphiné and Briançon, called Vaux de R ne. The first authentic mention of the Gallic reformer ap ears in the Chronicle of Laon, under the year 1173. H is there introduced to our notice as a citizen of Lyon, w , having amassed considerable wealth by usurious practi s, had his conscience alarmed in a very remarkable m nner. One Sunday, in the year 1173, hearing a Troub our in the streets of the city, reciting passages from the R naunt called the "Life of Alexis," Valdo invited him h e, and listened with earnest attention to the whole of th poem. Alexis, as the legend tells us, was a saint of e nent piety, who was so dead to all the attractions of this w ld, that he fled from the house of a wealthy father, and le his young bride on the day of his marriage, to devote hi self to a life of poverty and mortification. After sevente n years of self-imposed exile, he returned to the paternal ab le, in the character of a mendicant, and for many years re ived daily relief at his father's door, without making hi self known. At his death a written paper revealed his se et. The narrative made a deep impression on the mind of aldo, of which the Troubadour[1] failed not to take adva tage. Moved by the serious discourse of his guest, V do went the next morning to unburthen his mind to a p st of great reputation in the city, and consulted him as to hat he should do for the attainment of Christian perfe ion. "If thou wouldest be perfect," was the answer, " o, sell all thou hast, and give to the poor." Valdo reso ed to obey the injunction to the very letter. He conve ed his property into money; he placed his two daughte in the convent of Fontevrault;[2] he distributed largely to e poor; he fed all who came to him three days in the w k; and on the festival of the assumption of the Virgin M y, he publicly proclaimed his intention of abandoning the service of mammon for that of God, and invited his fellow-citizens to follow his example. His wife, alarmed by these proceedings, implored the archbishop of Lyon to check the imprudent zeal of her husband, and that prelate and his suffragan, the bishop of Bourg-en-Bresse, gave Valdo some advice upon the occasion. Nothing however could damp his ardour; he persevered in his system of self-denial, and gained over a number of followers, who imitated his example, by embracing voluntary poverty, and by ministering bountifully to the wants of the poor.

A severe famine, which desolated the whole of Gaul at this time, gave them full opportunities of exercising the virtue of almsgiving, and they did so to the very utmost. Forming themselves into a fraternity, under the name of "Poor Men of Lyon," Valdo and his disciples at first made themselves conspicuous, by the sanctity of their lives only, but they soon began to attract further notice, by rebuking the rapaciousness and corrupt manners of the ecclesiastical and monkish orders. Here indeed was ample room for complaint: the ignorance and profligacy of the clergy, with some few bright exceptions, were the scandal of the church; and we require not the evidence of her adversaries—that of churchmen is quite sufficient—to establish this fact. It was a long course of wickedness in high places, and inefficiency on the part of those who called themselves the successors of the apostles, and the lawfully appointed ministers of Christ, which prepared the way for such a work as Valdo had to perform. But though he was one of the most eminent of early reformers, he was not the first to rouse Christendom from her unholy slumbers, and to say to those who slept, "awake!" Even before the scenes at Orleans in 1017, described by Glaber, voices had been heard, almost simultaneously, from Germany, France, and Italy, protesting against ecclesiastical corruptions; and we have the testimony of Bernard of Clairvaux, Peter of Clugny, and Evervinus of Cologne, who flourished between 1120 and 1150, to prove that, in that age, zealous and holy men were to be found, who declaimed against the vices and errors of the clergy, and proposed schemes of reformation.

By degrees, Valdo and the Poor Men of Lyon took upon themselves to exhort and to admonish, in fact to preach both in public and private. "Cœperunt paulatim," says the Chronicle of Laon, "tam publicis quam privatis admonitionibus sua et aliena culpare peccata." This was no slight matter of exasperation to a powerful body of men, whose priesthood was disgraced by priestcraft; but another proceeding of the reformer called forth their fiercest animosity. Valdo employed his time and property on one of the most useful and sacred objects to which a Christian could dedicate himself, the translation and circulation of Scripture in the vernacular tongue of the country, and for this he has never been forgiven by the successors of Hildebrand. To lock up Scripture, or to refuse the free use of it, was one of the novelties of an imperious and jealous church, and a disproof of the infallibility of popes and councils. In 841, the third council of Tours decreed, in its seventh canon, that bishops should promote scriptural instruction by translations of certain homilies and psalms in the vulgar tongue, "in rusticam Romanam linguam aut Theotiscam." In the twelfth and thirteenth centuries, a new light broke in upon Christian hierarchs, or they began to prefer darkness to light, and it was forbidden by coun-

---

In those days, many of the jongleurs and wandering troubadours often combined the several characters of pedlars, poets, and religious in uctors. They were a privileged order, whose harp, and song, and news, obtained for them admission into the castles of the barons, an he houses of the citizens. They would oftentimes begin by diverting their hearers, and, after touching some string which roused devo feelings, they would launch into sacred subjects, produce transcripts of Scripture, and converse on the deepest points of sacred truth.

n Poitou. A fraternity, called "The Poor of Christ," was settled here in 1103, under the government of a woman; an institution wh h has been severely attacked by Bayle.

cils to turn Scripture into vernacular languages for the use of the people. The manner in which Valdo set about his work, attests the soundness of his judgment, as well as the devotedness of his zeal. In the first place, he obtained the assistance of three eminent scholars, who had a critical acquaintance with the sacred writings; Bernard of Ydros, who was afterwards held in great estimation by the Dominican order; Stephen of Ansa or Empsa, eminent as a grammarian and linguist, who was promoted in course of time to a benefice in the city of Lyon;[1] and John of Lugio,[2] a biblical scholar of high reputation, who became the head of a religious congregation in Lombardy. The latter was the only one of the three who remained faithful to the cause of Valdo, and the silence of the two former, after they deserted him, as to any spots in his moral character, is a strong attestation in his favour. Stephen translated into the Gallo-Provençal language, John examined authorities and corrected the translations, and Bernard transcribed the version so prepared for the use of the copyists, who were to multiply copies for general circulation. But not satisfied with these means for procuring correct translations of the Bible, Valdo also collected sentences of the ancient fathers, particularly of Ambrose, Augustin, Gregory, and Jerome,[3] in illustration of the books of Scripture, of which copies were to be made; and these, too, he put in circulation to serve as notes or comments for the help of his Scripture readers. This being done, the master and his disciples committed many passages of Scripture to memory, and thus armed with the word of God, they went forth into the streets and the houses of Lyon, and into the villages of the neighbourhood, and delivered the gospel message with so much ardour and success, as largely to increase the number of their adherents. In some few places the churches were open to them by consent of the secular clergy; and where they could not have access to the sanctuaries, they preached and expounded Scripture in the streets and highways. It is uncertain how many books of the Bible were translated and circulated by the Lyonese Reformer, and the Poor Men of Lyons. Walter Mapes says, that the volume of Valdo which was presented to Pope Alexander, contained the text and a gloss of the *Psalms*, and *of many books* of the Old and New Testament. Reiner leads us to believe, that the whole of the New Testament was circulated by them, in the vulgar tongue. Stephen de Borbone speaks only of *many books* of the Bible, without designating them. The effect produced by the gospel tidings, as they were delivered by these new expounders, was felt like an electric spark throughout the whole of the province and diocese of Lyon. The common people heard them gladly, for now, for the first time in their lives, they listened to preachers who spoke in the language of Scripture, and pointed to the sacred page, in confirmation of every doctrine which they urged.

After persevering in this course for five years, Valdo found that the increasing enmity of the monks and clergy of Lyons had become dangerous to him. In 1178, he therefore took the bold and honest step of going to Rome, to make his views known to the sovereign pontiff Alexander III. and to request the papal sanction to his proceedings.[4] In fact, he asked the pope to recognize his fraternity of the "Poor Men of Lyon" as an ecclesiastical order of authorised preachers, and licensed circulators of Scripture. Never did the founder of a religious community experience a better reception from prince or pontiff. The pope embraced Valdo, "Valdesium amplexatus est papa, approbans votum quod fuerat voluntariæ paupertatis, &c." says the faithful narrator whom we have before cited.[5] He approved of the order of the "Poor Men of Lyon" as professors of voluntary poverty; but while he gave them a limited license as preachers, he forbade them to exercise it without the especial permission of the regular priesthood. Up to this period the conduct of Valdo and his disciples had been irreproachable even at Rome, or the pope would not have shown him such favour. In fact, all his proceedings hitherto had been strongly characteristic of one who acted as a dutiful member of the holy Catholic church. It was a church-legend which first made a serious impression upon him; it was to a priest that he first went for spiritual counsel, after his conscience had been awakened. The adviser whom he next consulted was a bishop; so closely did he observe the canon of Ignatius, "nihil sine episcopo." He placed his daughters in a convent; an act which savoured of the most rigid adherence to ecclesiastical customs. The holy book on which the church builds its faith was his constant study; and his chosen fellow-labourers in the work of transcribing and translating, were members of the sacerdotal order. So blameless was his career, and so conscious was he himself of the purity of his motives, that he sought, as we have shewn, an interview with him who was called the supreme Head of the Church, and was received with indulgence and honour. The child-like submission and meekness of this exemplary Christian were carried to such an extent, that for a time he obeyed the pope, and forbore to preach, except on the terms imposed upon him. At length however his ardent zeal, sharpened by the opposition of the clergy, who hated the spirituality and fervour which condemned their own negligence, could no longer be restrained, and he preached without their permission. He and his disciples were commanded by episcopal authority not to speak at all, nor preach in the name of Jesus; they answered as Peter and John had done before the council at Jerusalem. They were accused of a presumptuous usurpation of the apostolic office, and were again admonished to be silent, on pain of the severest ecclesiastical censure. They however persevered and from disobedience, says one of our historical witnesses they fell into contumacy, and from contumacy, into th penalty of excommunication.[6] The fearful sentence, which was meant to deprive them of all the ordinances of religion to exclude them from the church and the altar, to den baptism to their children, burial to their dead, marriage t their betrothed, and to banish them from Lyon, was pass ed by John de Bellesmains, archbishop of Lyon, in 1181 Pope Lucius confirmed the excommunication in 118 In the Lateran council of 1215, the same dread sentenc was again fulminated against all who should embrace thei doctrines, or receive them into their houses. They wer driven ignominiously from their homes; and seeing no hop of producing a reformation in the bosom of the imperiou church, out of which they had been cast, or of being re ceived back into it, without doing violence to their con sciences, Valdo and his followers had no other alternati than to form themselves into a community, in which pe sons, selected from their own body, were appointed to pe form the offices of religion, and administer the sacraments Thus Valdo and the "Poor Men," or "Valdenses of Lyo were not voluntary seceders from the dominant churc but they were thrust out of her, and Rome, contrary her usual policy, which is to turn enthusiasm to accou i her own favour, if not in her own way, has to thank herself for a schism, which rent from her communion some o the most devout Christians of France, and of several o her countries, in which the doctrines of the Lyonese ref mers gradually found recipients.

[6] Stephen de Borbone, ut supra.

[7] From all we can collect, this was not done until after very mature deliberation and consultation with religious persons in other cou tries, whose eyes had been opened to the corruptions of the Latin church. Moneta, the most dispassionate of all their accusers, stat that Valdo "ordinem habuit ab universitate fratrum suorum," and that a Lombard separatist was his authority for this statement. M neta contra Valdenses, lib. v. c. 1.

The "Poor Men of Lyon," exiled from their native city, f nd refuge in the secluded parts of Provence and Lomb dy, and were hospitably received there by persons who h d kindred opinions. The document, which states this, p nts to religious communities on each side of the Cottian A ps, to the territorial Waldenses of ecclesiastical history, w ose situation providentially enabled them to maintain in s ety opinions at variance with those of Rome. A rem rkable passage in the authority which gives us this inf mation, adds that the exiles imbibed the errors of these s alpine heretics, and became, when they mingled with t em, the most determined enemies of the church.[1]

From this time the "Poor Men of Lyon," and the Vald ses (territorially so called) of the Cottian Alps, became m xed up in ecclesiastical history, as if they were one and t same. But the former, after their exile from Lyon, w re never gathered together in any one district or prov ce as a distinct people, but were scattered among the r ions; and those who embraced their tenets, sometimes adh red to them openly, sometimes secretly, but never in suffic nt numbers, or local strength, to constitute a church. W hen or where Valdo died, remains in obscurity, but his n me was given to almost every sect who protested against p al usurpation.

A happier destiny was reserved for the subalpine Vald nses. They were the inhabitants of a mountain tract of c untry, where they constituted the majority of the popul ion; and at this hour the remains of them form an establ hed church, and a well known and intelligent religious c mmunity in a region of Piedmont.

The persecutions which, for 200 years, swept Europe of a who were called Valdenses, except in the subalpine t ritories, were an outrage upon humanity, and have fixed a indelible stigma on the church of Rome. Her offende pride was satisfied with nothing short of death, whene er she could cause it to be inflicted on those who dared t dispute her authority; and Stephen de Borbone relates, w hout a breath of compunction, that he was present when e hty of Valdo's sect were condemned to the flames. A bericus the chronicler states the number to have been 1 2, and speaks of it as a sacrifice of a sweet-smelling sav ur acceptable to the Lord,—"Holocaustum placabile Dom no." But with all the animosity of the early persecut s of Valdo and his disciples, they have not recorded one w ll authenticated accusation of immorality against them. I is a singular attestation to the moral and religious char ter of Valdo, that none of those calumnies, which were a erwards circulated by Roman catholic writers, were adv nced against him during his lifetime. The chronicle o Laon briefly mentions his disobedience in preaching w thout permission, and the ruin and scandal which it occ ioned.

Walter Mapes, who was present at Rome when Valdo a pealed to the pope, indulges in a vein of irony against t e Valdesii, who wanted to reform the church; he ridicule them as a parcel of "houseless,"[2] "bare-footed," "indigent," and "illiterate idiots," unworthy of notice; but utters not a word against their morality. On the contrary, in one of those unguarded expressions, which truth wrings from prejudice, he admitted that they preserved the faith, and were ready to die for the sake of the Lord Jesus Christ.[3]

The earliest calumniator of "the Poor Men of Lyon," *Alanus insignis theologus*, who inveighed with the utmost severity against them, said nothing worse of their founder, than that he presumed to preach without inspiration or literature, to call himself an apostle without a mission, and a teacher without learning.[4]

Moneta,[5] who wrote a history of the Valdenses of Lyon, within half a century after their first appearance, speaks of a certain man named Valdesius, from whom they derived their origin, without casting any stain upon his moral fame; and though Moneta was an inquisitor, the bosom friend of Dominic, and condemned heretics to the flames, and wrote forty folio pages in defence of persecution, yet he admits that the Valdenses still respected the validity of Romish ordination, received the Old as well as the New Testament, and did not give reins to licentiousness.

Peter, the monk of Vaux Sernay,[6] who wrote in 1217, and was clamorous for the total extinction of the Albigenses by fire and sword, mentions the name of *Waldius*, the founder of a sect of heretics called *Waldenses*, without a syllable of reproach; and states the principal errors of those schismatics to have been "an affected imitation of the apostles, refusal to take an oath, denial of the power of the magistrate to inflict the punishment of death, and presuming, because they were sandal-wearers,[7] to celebrate the Eucharist without episcopal ordination."

Reiner,[8] whose work bears the date of 1250, has no charge to bring against Valdo, and no other against his followers than their separation from, and hostility to, the church of Rome, their use of Scripture in the vulgar tongue, and the estimation in which they held those of their sect who embraced a life of poverty, and believed in justification by faith. We may therefore consider that all the licentious tales which have been told at the expense of Valdo and his disciples, were the invention of after times. That individuals among them may have broached some extravagant and fanatical dogmas, is not improbable; but we have no contemporary evidence in proof of their having departed from the strictest rules of moral and religious purity, or of their having been guilty of any other than the unpardonable offence of disobeying a spiritual authority, which had become as tyrannical in the exercise of its power, as it was remiss in the discharge of the sacred trusts committed to it. "The worst that can be said of them," said the inquisitor Reiner, whose business it was to accuse and hunt them down, "is, that they detest the Roman church." (D. F.)

VALENCE, an arrondissement in the department of the Drome, in the south-east of France. It is thirty-five and a-half square miles in extent, is divided into ten cantons, distributed into 101 communes, and in 1836 contained 138,546 inhabitants. The capital of the same name stands on the left bank of the Rhone, is surrounded with walls, and has an ancient castle, in which pope Pius the sixth died in 1799. In 1836 it contained 10,967 inhabitants. They carry on cotton manufactories on a large scale, and make

The Greek ritualists inform us that the sandal was a mark of sacerdotal dignity. Some very curious mistakes have occurred from the ms Xabatati and Sabatati applied to the followers of Valdo. The term is derived from *sabot*, a sandal.

Reinerus de Sectis Antiq. Her. c. 4, 5. Bibliotheca Patrum, vol. iv.

gloves and silk hoes, and trade extensively in wine. Lat. 44. 55. 59. Long. 4. 47. 20. W.

VALENCIA, a province, or, as it is called from its ancient title, a kingdom of Spain. It extends over 643 square leagues, and its population amounts to 825,059 souls, being the most densely peopled part of the peninsula. It appears by authentic data taken in the year 1808, that in the course of forty years prior to that date, the population had been doubled. Valencia is bounded on the north by Catalonia and part of Aragon, on the west by New Castile, on the south by Murcia, and on the east by the Mediterranean sea. Although, like the rest of Spain, Valencia is a mountainous country, so that two-thirds of it may be considered as desolate elevations, yet the rest of the province consists of level and beautiful valleys, covered with exquisite fruits, and other productions of a most valuable kind, as silk, rice, hemp, flax, and grain. It does not, however, raise wheat sufficient for its own consumption. Alicant is the most considerable trading port in Valencia. It is in the form of a half-moon on the shores of the sea. From this port the principal productions of the province are shipped for the different foreign markets. Notwithstanding the fertility of the soil, and the assiduous care exercised on the cultivation of it, the peasantry are in a state of poverty. Most of the lands are either the property of the corporations, or of nobles who hold them under the strict entail denominated mayorazo. These let them to tenants, and they again to sub-tenants; by which process the rent is raised to a rate that impoverishes the actual cultivators. The climate of this province on the sea-shore is by no means healthy, but at a little distance from the coast, where it is gently elevated, it is very favourable to longevity; and even on the coast they have been less severely visited by epidemic fevers than in the provinces of Andalusia and Murcia.

Valencia, a city of Spain, the capital of the province or kingdom of the same name. It is situated on the river Turia, which is not navigable, but is principally beneficial by its being adapted to the purposes of irrigation. It has however six spacious bridges over it, though at some seasons it is fordable. The city is about two miles from the sea, where the fortress of Graco is built to protect the landing, and a mole is projected, which, when accomplished, will be of vast advantage. The city is large, and nearly forms a circle. It has lofty walls of ancient construction, with some of the towers of the same date still standing. The streets are narrow and crooked, and almost destitute of pavement, and the whole place is very filthy.

Valencia is the seat of an archbishop; and the cathedral is endowed with an enormous revenue, great part of which is expended in the erection of religious edifices. The cathedral is a very large Gothic pile of building, but with a mixture of more modern taste, and has not much to recommend it; but the entrance is adorned in a most profuse manner, and contains some very good pictures. The other churches and convents are very numerous, and no city, even in Spain, has a greater proportion of ecclesiastics. The lorza or exchange is the best of the secular buildings. It is of the date of the fifteenth century, when architectural taste in Spain was at its zenith.

The city abounds with Roman antiquities; but the Moors, from having been early dispossessed of this province, have left behind them much fewer of their best remains than in those provinces which they held to a later period, when their manners had become more refined, and their means of erecting durable edifices more extensive.

The principal manufacture of this city is that of silk in all its various branches. It employs about 25,000 persons, and the silk annually used amounts to about 900,000 pounds. Sometimes the produce of silk is insufficient for the supply of all the looms, in which case many of the poor are unemployed, and to remedy this, a decree is in force, preventing the exportation of raw silk. The inhabitants of Valencia amount to about 160,000, of whom 100,000 are within the walls, and the rest in the extensive suburbs, where the working people employed in the silk manufactory reside.

Valencia contains a university, two public libraries, a seminary for youths of noble families, and several printing-offices. Lat. 39. 29. Long. 0. 24. W.

VALENCIENNES, a strongly fortified city of France, in the department of the North, and the arrondissement of Douay. It stands on the river Scheldt, where the Rhonelle falls into that stream. It has a powerful citadel and deep trenches. After a brave defence, it was captured by the duke of York in 1793. It is a place of great manufacturing industry. The city is ill built, with narrow and crooked streets, and in 1836 contained 18,953 inhabitants. Lat. 50. 21. Long. 3. 25. E.

VALENTINIANS, a sect of Christian heretics, who sprung up in the second century, and were so called from their leader Valentinus. The Valentinians were only a branch of the Gnostics, who realised or personified the Platonic ideas concerning the Deity, whom they called *Pleroma* or *Plenitude*.

VALERIUS FLACCUS, Caius. See Flaccus.

VALERIUS MAXIMUS, a Latin writer of the age of Tiberius. His *prænomen* is by some supposed to have been Publius, by others Marcus. We learn from different passages of his own work, that he served in Asia with Sextus Pompeius, and returned to Rome after the death of Sejanus, or towards the end of the reign of Tiberius. This S. Pompeius was consul during the year when Augustus died. The work of Valerius, "Dictorum Factorumque memorabilium libri novem," he inscribed to the successor of that emperor. It is valuable, not from any peculiar elegance of diction, but for its copious and variegated collection of ancient anecdotes of public and private life. According to the opinion of some critics, his composition has not descended to our times in its original form, but as it was reduced to an epitome, either by Julius Paris, or by Januarius Nepotianus. It is however far from being certain that his work was remodelled. See Vossius de Historicis Latinis, p. 123, and Fabricii Bibliotheca Latina, tom. ii. p. 50. edit. Ernesti.

The earliest edition of Valerius Maximus is supposed to have been printed at Strasburg by Mentelin. It is a folio volume without date, but conjectured to be at least as early as the year 1470. An edition which appeared soon after this period, has very frequently been described as the first. It was printed by P. Schoeffer de Gernshem, Mogunt. 1471, fol. And the same year produced an edition by V. de Spira, Venet. 1471, fol. After some intermediate editions, other two proceeded from the press of Aldus, Venet. 1502, 1514. 8vo. Many editions afterwards appeared, several with annotations by Pighius, and a few with brief notes by Lipsius. Among the early impressions, we may specify that which contains the annotations of Pighius and Colerus, Francof. 1627, 8vo. A very elaborate and valuable edition, accompanied with a great body of notes, was at length published by Torrenius, Leidæ, 1726, 4to. Several other editions have more recently appeared; and among these we may venture to recommend that of Kapp, Lipsiæ, 1782, 8vo.

VALERY, St, a sea-port of France, in the department of the Lower Seine, and the arrondissement of Yvetot. On the English channel it has a good tide-harbour, from which the herring and other fisheries are extensively carried on, and where many ships are built. Lat. 49. 52. 12. Long. 4. 35. 20. The inhabitants in 1836 amounted to 5328.

VALET, a French term, used as a common name for domestic men-servants.

VALETTA, La, the capital of the island of Malta, is situated on the east side of the island, in 14° 30′ E. long.

36° 53′ N. lat. It was founded in 1566 by the celebrated grandmaster of the same name, and received munificent contributions from the pope, and from the kings of Spain, France, and Portugal, and it is now one of the first towns in Europe. It consists of five parts, La Valetta or Citta Nuova, Citta Vittoriosa, Senleya or the isle of St. Michael, Barmola, and Cottonera. The situation of the town is beautiful, the streets are regular, and well paved with lava. The public buildings and private houses are of a very superior order; they are built of stone, with flat or terraced roofs. Water is supplied by means of an aqueduct seventeen thousand yards long, conveying fifty-eight gallons per minute. The city contains above twenty churches, great and small, besides the cathedral. The principal edifices are the cathedral, the palace of the grandmasters, the lodges of the different languages, the conservatory, the university, the treasury, the palace of justice, the hospital, the Monte di Pieta, the barracks, the theatre, and the exchange. These buildings are distinguished by the elegance and chasteness of their architecture. The public library contains about 100,000 volumes, and there is also an extensive museum. The total population of the island in [illegible], including the troops, amounted to 106,614, of which about 40,000 resided in the capital.

VALLADOLID, one of the provinces into which the kingdom of Leon in Spain is divided. It extends over 271 square leagues, and has a population of 187,390 souls. It is situated in a country destitute of trees, except an occasional mixture of fir woods in some of the more sandy soils. From being thus denuded of trees, it appears more barren than it in reality is; for it produces good crops of corn, especially of wheat, when the summer is moist, and on all those spots where either natural or artificial irrigation is practised; but like all the plains of Castile and Leon, it suffers most severely in dry seasons. The canal of Castile runs through a portion of this department, and as it is designed for irrigation, as well as for navigation, it is very beneficial as far as it extends; and if ever it should be completed, so as to unite the river Santander with the Ebro and the Douro, it will be of incalculable advantage to the whole of Valladolid.

VALLADOLID, a city of Spain in the province of Leon, and the capital of a district of the same name. It is situated on a plain at the spot where the rivers Pisuerga and Esguiva form a junction; and the waters of the latter, divided into two branches, pass through a part of the city. The country around it is not productive, but might be made highly fertile by a small expense in irrigation. The city is large, and contains a population of about 30,000 souls. The streets are narrow and crooked, and exhibit signs of decay, but the principal square is very magnificent, and has many remains of that ancient grandeur which belonged to it when this place was a royal residence, and the palace, now hastening to ruin, was occupied by the court of Philip the Third. The convent of the Dominicans is a fine Gothic pile, and some other ecclesiastical edifices are both large and venerable; but the university, which was once flourishing, is hastening to decay, and has very few students, and these are constantly diminishing in number. Valladolid is situated in Lat. 41. 42.

VALOGNES, an arrondisement of the department of Manche in France. It extends over 406 square miles, and comprehends seven cantons, which are divided into 118 communes, with 95,950 inhabitants in 1836. The capital is the city of the same name, nine miles from the sea, on the banks of the river Werderet. It is a place of manufacturing industry, in which cloths called *draps de Valognes*, are extensively made. In 1836 it contained 1050 houses, and 6555 inhabitants. Near to it are the remains of an ancient city and an amphitheatre. Lat. 49. 30. 26. Long. 1. 33. 45. W.

VALLEGGIO, a city of Italy, in the delegation of Verona, and under the Austrian government of Milan. It stands on the river Mincio, and contains 5350 inhabitants, chiefly employed in the culture of silk. Near to it is Borghetto, where, in 1796, the Austrian army was defeated by Bonaparte.

VALVE, in *Hydraulics*, *Pneumatics*, &c. is a kind of lid or cover of a tube or vessel, so contrived as to open one way, but which, the more forcibly it is pressed the other way, the closer it shuts the aperture; so that it either admits the entrance of a fluid into the tube or vessel, and prevents its return; or admits its escape, and prevents its re-entrance.

VANBRUGH, SIR JOHN, a very eminent dramatic writer, descended from a family originally of Ghent in Flanders. The persecution of the protestants by the duke of Alva drove his grandfather to London, where he established himself as a merchant. His son Giles went to reside in the city of Chester; and there it is supposed that he carried on the business of a sugar-baker. He is mentioned as one of those worthy citizens of Chester, who, although in communion with the church of England, attended the week-day lectures of Matthew Henry, "and always treated him with great and sincere respect."[1] Whatever was his trade, he became rich by it, and married the youngest daughter of Sir Dudley Carleton. By that lady he had eight sons, of whom John was the second. The precise period of his birth, though it probably happened soon after the Restoration, is not known; and we are also left to conjecture what may have been the variety and extent of his early studies. His father's wealth, and the evidence of his own writings, would lead us to suppose that his education was not neglected. At an early age, he served as an ensign in the army, but after a short trial abandoned the military profession. What led to this precipitate retirement does not appear; but it is easy to imagine a thousand causes of disgust to a service, in which "preferment goes by letter and affection." Vanbrugh was a younger brother; and being in all likelihood attracted to the profession of arms by no higher motives than a juvenile fondness for feathers and scarlet cloth, which soon become objects of indifference to the silliest person that wears them, he resolved to pursue some mode of life which might be favourably contrasted with the glittering penury of a subaltern.

In the absence of other resources, he thought of writing for the stage; an occupation usually productive of more vexation than emolument. In those days, however, dramatic writing, if the most precarious, was also the most profitable species of literary labour. And the dramatist has this advantage over every other man of letters, that he is either greeted by sudden applause, or relieved from the horrors of suspense by immediate condemnation. In some provincial town where his regiment was stationed, Vanbrugh formed the acquaintance of Sir Thomas Skipwith, from whom, Cibber, in his Apology for his Life, states that "he happened to receive a particular obligation," of what nature he does not explain. By way of showing his gratitude to Sir Thomas, who had some share in the Theatre Royal, Drury Lane, he wrote for that house the comedy of the Relapse, or Virtue in Danger. This play, which is a sequel to Cibber's Love's Last Shift, was acted in 1697, with complete success. The Relapse was a very seasonable acquisition to the company, whose affairs were in great disorder, owing to the secession of Betterton and the principal comedians, who had been provoked by the tyranny of the patentees to erect an independent standard in Lincoln's-

Vanbrugh. Inn-Fields. Soon after this comedy had been performed, Lord Halifax, who was a great admirer of Betterton, requested Vanbrugh to finish the Provoked Wife, which had been shown to his lordship in an imperfect state, and give it to the other house. This solicitation he was unable to resist; nor did his compliance give any offence to Sir Thomas Skipwith. The Provoked Wife was performed in 1697, and was received with as much applause as the Relapse. In the preface to that comedy he says, "there is not one woman of real reputation in town, but, when she has read it impartially over in her closet, will find it so innocent, she'll think it no affront to her prayer-book to lay it upon the same shelf." This reminds us of Smollett, who flattered himself that in his novel of Peregrine Pickle there would not be found a single "adventure, phrase, or insinuation, that could be construed by the most delicate reader into a trespass upon the rules of decorum!" Of the tendency of Vanbrugh's writings, a very different opinion was formed by the arch-enemy of the theatre, Jeremy Collier, who, in his celebrated View of the Immorality of the Stage, assigned him a conspicuous place among the offenders against religion and decency. Vanbrugh replied in "A Short Vindication of the Relapse and the Provok'd Wife from Immorality and Prophaneness." Lond. 1698, 8vo. This tract contains more wit than argument; and the grave charge brought against him, Sir John Vanbrugh rebuts too much in the manner of Sir John Falstaff, another ingenious sophist of equestrian rank. Although petulant enough, however, he was not angry, like some of the other antagonists of Collier. The world acknowledged that he had not written foolishly, and it gave him very little concern that, in the opinion of one rigid censor, he had written wickedly. Lefebvre-Cauchy has said in a few words all that can be urged in extenuation of his offence: "Malheureusement la plus grande licence régnait alors sur la scène Anglaise, et l'on ne devait pas attendre qu'un jeune militaire cherchât à en épurer la morale."[1]

During the same year, 1697, Vanbrugh, who was again at liberty to oblige his friend Sir Thomas Skipwith, brought out Esop, a comedy in two parts, at Drury Lane. This comedy, which was a translation, with the addition of some new characters, from the French of Boursault, met with a much more moderate share of success than its predecessors. Pope is said to have complimented Vanbrugh by saying, that the fables in his Esop were written in the true style of La Fontaine, very much to the surprise of the dramatist, who knew nothing of La Fontaine or his productions. Esop was followed in 1700 by the Pilgrim, and in 1702 by the False Friend. About this period was finished a theatre in the Haymarket, for which Vanbrugh had sufficient interest to procure thirty subscriptions at one hundred pounds each. On the foundation-stone of this structure were inscribed the words "Little Whig," in compliment to Lady Sunderland, the second daughter of the duke of Marlborough. The management of the house was conducted by Congreve and Vanbrugh, in whose company the names of Betterton and his principal adherents were enrolled. That great tragedian and his associates had not found their account in deserting the patentees, and now hoped that a succession of new pieces from the chief favourites of the town would speedily retrieve their affairs. They were however disappointed in their expectations. The house was badly adapted for the conveyance of sound; and although Vanbrugh wrote with great despatch, Congreve was too jealous of his fame to suffer any thing to come from his hands that had not been polished to the most dazzling brilliancy. About this time the Italian opera, though yet in an embryo form, had found favour in England; and to humour the prevailing taste, the new managers opened their theatre with a piece set to Italian music, called the Triumph of Love, which brought nothing into the treasury. In 1705 Vanbrugh produced the Confederacy, founded on the "Bourgeois à la mode" of Dancour. This piece was also coldly received; and Congreve quitted with some precipitation what he considered to be a falling house. Vanbrugh was now left to his own resources, and in the year 1706 produced the Cuckold in Conceit, Squire Treelooby, and the Mistake, from the "Cocu Imaginaire," the "Monsieur de Pourceaugnac," and the "Depit Amoreux" of Moliere. The terse antithesis and epigrammatic point of the French comedian were little to the taste of an English audience; and Vanbrugh, now thoroughly disgusted with theatrical management, assigned his house and properties to Mr. Owen Swiney, upon condition of receiving five pounds for every acting night, or an income not exceeding two hundred per annum. But if he had no dexterity in managing a theatre, he possessed to a wonderful degree the more important art of endearing himself to powerful friends. A lively writer is often a very sombre companion; but Vanbrugh's most "entertaining scenes," says Cibber, who knew him well, "seemed to be no more than his common conversation committed to paper." Great men are not always in haste to provide for the needy companions of their pleasures, who seldom acquire any thing by such exalted intercourse, but a taste for enjoyments which they can rarely secure. Such helpless witlings it is often impossible to rescue from the miseries of dependence, which seems t be their natural element. But Vanbrugh was a man o true genius, whom it was reputable to befriend, and a man of energy, who was never plunged in disreputable indigence, and who was perfectly able to befriend himself Dignity and wealth now flowed fast upon him. At Greenwich in 1714 he received the honour of knighthood; in 1715 he was appointed comptroller of the royal works; and in the ensuing year, surveyor of the works at Greenwich Hospital. Some years before, he had been made Clarencieux king-at-arms, an office for which he had no qualifications. His appointment created such an outcry in the College of Heralds, that he had the modesty to resign. Hi successor however had recourse to more palatable arguments than abuse. In 1715 he produced a farce called the Country House.

At one period of his life, Vanbrugh paid a visit to France where he met with a remarkable adventure. When surveying some fortifications with minute attention, he attracted the notice of an engineer, upon whose information he was handed over to the civil authorities, and conveyed to the Bastile. Upon the news of this extraordinary incarceration, he was visited by some of the French nobility whose language he spoke with perfect fluency and elegance and who were so much charmed by his wit and vivacity that they exerted themselves strenuously in his behalf, and he was speedily restored to liberty. In that gloomy edifice, which had often re-echoed to the groans of despair Vanbrugh passed some of the most pleasant hours of hi life. It is singular enough that a similar incident occurred to Hogarth, who was taken into custody when sketching the gate of Calais. But that morose and irritable humourist had no distinguished visitors to cheer the gloom of hi confinement, and commemorated this disagreeable event o his history in the print entitled, "O, the Roast Beef o Old England!"

Although he had retired from the bustle of theatrica management, Vanbrugh still continued his dramatic labours and was engaged in writing the Provoked Husband, when his hand was arrested by the stroke of death. This even t k place at his house in Whitehall, on the 26th of March 1 26. His widow survived till the year 1776, when she d d at the age of ninety. Their only son, an ensign in the s ond regiment of foot guards, died in 1745 of the wounds w ich he had received in a battle fought near Tournay.

---

[1] Biographie Universelle, tom. xlvii. p. 418.

The Provoked Husband was admirably finished by Cib- b , and is still a favourite piece; every comic actress of a eminence including Lady Townly in her list of parts. I on the revival of the Provoked Wife, Vanbrugh had a eady exhibited some regard to decency, by divesting S John Brute of his clerical costume in a scene of the f rth act, and providing him with the habiliments of a f ionable demirep. In his prologue to the Provoked H sband, Cibber informs us that the departed dramatist d igned, if his life had been prolonged, to have made still m re important sacrifices at the shrine of decorum.

As an architect, Sir John Vanbrugh is accused by Swift of s aling his plans from the edifices erected by children with c ds or mud; and after he had built St. John's Church in estminster, some Pasquin of the time suggested the fol- l ving retaliation:

Lie heavy on him, earth, for he
Laid many a heavy load on thee.

hen Pope remonstrated with Swift upon his speaking with s h unmeasured contempt of one of the most remarkable n of his time, the dean said that Vanbrugh was a puppy a l a coxcomb, although he knew nothing of him but that he s neither a Tory nor a high-churchman. At last he became amed of his injustice; and in the preface to the Miscel- l ies, collected by Pope and himself, an ample apology is de for his unseasonable merriment at the expense of "a n of wit and honour."

Vanbrugh is now to be viewed in the character of a drama- writer. In assimilating remote ideas, which is the proper ovince of wit, he is only inferior to Congreve, who was so pro- gal in his use of this faculty, that Pope is induced to inquire f Congreve's fools are fools indeed." The personages of ngreve's scenes are reproductions of the obsolete charac- s of the old comedy, and his dialogue is a perpetual blaze wit. The wit of the fine gentleman, and that of his key, are no doubt discriminated with great nicety; but th utter such brilliant things, every time they have occa- n to speak, as perhaps no man but Congreve himself uld have devised. If this is a fault, it is one which modern amatists, Sheridan alone excepted, have avoided with sin- lar success. Although Vanbrugh is less liberal than Con- eve in his expenditure of wit, he was a more faithful painter the manners of the age in which he lived; his characters are e men and women of the time, and appropriate language put in the mouth of each. And if he is deficient in refine- ent, he is never deficient in wit and vivacity. "There something so catching to the ear," says Cibber, "so easy to the memory in all he wrote, that it has been served by all the actors of my time, that the style of no thor whatsoever gave their memory less trouble than that Sir John Vanbrugh; which I myself, who have been charg- with several of his strongest characters, can confirm by a easing experience." Had Vanbrugh lived a few years nger, he would probably have enriched the stage with enes of equal purity and elegance, and his easy and har- onious lines, which are too often but a captivating garb r maxims of depravity, might have been a graceful vehicle r sentiments of virtue, and instructed the understanding, hile they improved the heart.
